THE NORWEGIAN RESEARCH PROGRAM ON THE  
BARENTS SEA CAPELIN STOCK

by

Are Dommasnes

Institute of Marine Research  
P.O. Box 1870-72, N-5011 Bergen, Norway

ABSTRACT

The aim of the Norwegian research program on the Barents Sea capelin stock is to provide information needed for management of the fishery. The cruise program for 1977 and the objectives of each cruise is discussed. The sampling program and processing of information is also described.

INTRODUCTION

Since 1964 the Norwegian capelin fishery in the Barents Sea has gradually increased in importance. In 1964 the Norwegian catch

was 19.626 metric tonnes, and in 1976 it was 1.929.567 metric tonnes. The Barents Sea capelin fishery is now by far the largest industrial fishery in Norway.

Parallel to the increase in importance of the Barents Sea capelin stock, the research effort on that stock has also increased. The Institute of Marine Research started its program of capelin investigations with a cruise in September 1960. In 1961 there was one cruise in February/March and one in August (MØLLER and OLSEN, 1962). In 1977 there is planned a number of Norwegian research cruises throughout the year to investigate the capelin stock in the Barents Sea.

The short range aim of the research is to obtain knowledge on the present state of the stock in order to advice the fishing industry and governmental planning agencies on the prospects for the next season and on possible management actions which may be necessary.

The long range aim of the research is to obtain a better understanding of the biological aspects governing the dynamics of the population: its growth pattern; changes in the growth pattern of individual fish and of the population as such when the physical or biological environment changes; factors that influence the place and time for spawning; factors that influence the survival of the larvae; and the reaction of the population to fishing pressure.

#### THE CRUISE PROGRAM

Since the Institute of Marine Research started its research program on the Barents Sea capelin, a pattern of yearly research cruises has developed to obtain the information that is necessary for management of the fishery. Vessels, time and area for the

cruises are chosen depending on what information is needed, when it is needed, and when and where the information is most readily available. As an example, the cruise program for 1977 is given in Table 1.

The two winter cruises in January, February and March (cruises no. 1a and 1b) have as their most immediate task to locate commercial concentrations of maturing capelin and follow the migration run towards the coast, collect samples of the capelin and record the hydrographic conditions in the area. In March some time is also set aside for an acoustic survey of immature capelin. An important aspect of these cruises is to describe the spawning run in terms of routes taken, hydrographic conditions and length and age composition of the spawning stock.

The next research cruise, no. 2, is concerned with investigations in coastal waters to locate the spawning sites and determine the time of spawning. The spawning areas are located mainly by collecting bottom samples with a Petersen grab, but also the school pattern seen on the echo sounder is used, and information obtained from the fishermen. Information from this cruise is used to decide whether any areas should be closed to fishing and, eventually, how the closed areas should be delineated.

The "summer cruise" (no. 3a) has as its immediate purpose to provide fresh information on the size of the capelin stock, its age composition, the average length of each yearclass, and the geographical distribution of the capelin before the summer fishery. In addition, the distribution of capelin 0-group is recorded from plankton samples. With the information from this cruise, it is decided whether regulation of the summer fishery is necessary and, eventually, which regulations should be introduced. This year conditions for employing the echo integration technique were very poor in June, mostly due to ice conditions, and the cruise had to be partly repeated in July (cruise no. 3b).

Cruises 4a and 4b in August-September are part of the International 0-group fish survey in the Barents Sea. These cruises combine acoustics and trawling to obtain distribution maps and abundance indices of the 0-groups of the most important species of fish in the area.

The capelin cruises in September - October, no. 5a and 5b, provide information on the state of the capelin stock before the winter fishery that starts in January. Management decisions concerning this fishery are based to a large extent on information from those cruises.

The "summer cruise" (no. 3a) in June and the "autumn cruises" (no. 5a and 5b) are the cruises where the capelin stock is assessed, using a combined trawl survey/echo integration technique (NAKKEN and DOMMASNES, 1975 and 1977).

#### SAMPLING, RECORDING OF DATA

Sampling of commercial catches at the fish meal plants is carried out as for herring and mackerel and is described by HAMRE, ULLTANG and ØSTVEDT (1974).

Fishing from the research vessels is done by means of pelagic trawl, bottom trawl or purse seine. A random sample of approximately 100 fish is taken from the catch. Non-random samples, and smaller or larger samples, are taken for special purposes.

The information is recorded on the standard form in Fig. 1. This form is also used for herring, sprat, and mackerel, and therefore has some columns that are not used for capelin.

In addition to sample number, date, geographical position, gear, etc., the following parameters may be recorded for each fish:

Length in mm, measured from the tip of the lower jaw (mouth closed) to the end of the ventral lobe of the caudal fin with the fin in natural position

Volume in milliliters

Sex

Maturity according to the revised Johansen scale drawn up for Atlanto-scandian herring (ANON. 1962).

Stomach fullness

Degree of digestion

Age, from otoliths

Radius of year-rings and total radius of otoliths.

On board the research vessels "G.O. Sars" and "Johan Hjort" capelin otoliths are usually measured on board, but when the samples are taken on other vessels measuring has to be done ashore.

Not all of the above parameters are recorded always. Often, particularly when the number of samples is large, only the length frequencies are recorded. In that case the form in Fig. 2 is used. If information on sex is wanted, a separate length frequency is recorded for each sex.

On most cruises with the "G.O. Sars" and "Johan Hjort" it is also standard procedure to record integrated echo intensity of the different species of fish encountered, as described by NAKKEN and DOMMASNES (1975).

#### PROCESSING OF SAMPLE DATA

During the stock assessment cruises punching of all material is done on board the "G.O. Sars". In the case of the "autumn cruise" (5a and 5b) the sample forms are transferred from the "Johan Hjort" to "G.O. Sars" for this purpose.

After the samples have been punched and recorded on tape they are run through a test program that is designed to detect errors in the recording and punching of data.

Programs to utilize the sample data have now been developed. The main purpose of the programs is to present the data in easily surveyable tables.

The following standard printouts are available:

Age versus length  
Weight versus length  
Weight versus age  
Maturity stage versus length  
Maturity stage versus age  
Sex versus length  
Sex versus age  
Stomach fullness versus length  
Stomach fullness versus age  
Back-calculated average length for each yearclass  
Back-calculated average growth each year for each  
yearclass

The tables can be presented for any chosen area and time period, or for any selection of samples. For routine printouts standard time periods and areas will be chosen. Application of the data in the tables to special problems can then be done either with a small desk-top calculator or with special computer programs.

In addition there is available from the stock assessment cruises biomass and number of each yearclass in the total stock and biomass of the spawning stock (NAKKEN and DOMMASNES, 1975 and 1977).

Most of these printouts can also be obtained from the computers on board the "G.O. Sars". As an example is shown in Fig. 3 a printout that gives total numbers,

mean lengths and biomass for each yearclass and for the spawning stock.

The calculation of age composition in the catches, based on a combination of age-length material from the research vessels and length frequencies from the commercial catches (HAMRE, ULLTANG and ØSTVEDT, 1974) will also be computerized.

Table 1. Norwegian research cruises to investigate the Barents Sea capelin stock in 1977.

Cruise no	Time period	Vessel	Purpose
1a	6 Jan.- -12 Mar.	"G.O. Sars"	Distribution, migration routes, age and size composition of capelin before and during the winter fishery. Combined with investigations on cod.
1b	6 Jan.- -20 Feb.	Chartered vessel	Distribution, migration routes, age and size composition of capelin before and during the winter fishery.
2	13-30 March	Chartered vessel	Localization of capelin spawning areas along the Norwegian coast. Time of spawning.
3a	30 May - -2 July	"G.O. Sars"	Distribution, quantity, age and size composition of capelin before the summer fishery. Distribution of 0-group capelin.
3b	10-27 July	"G.O. Sars"	Distribution, quantity, age and size composition of capelin before the summer fishery.
4a	17 Aug.- -14 Sept.	"G.O. Sars"	International 0-group survey in the Barents Sea. Distribution and quantity of 0-group fish, including capelin.
4b	17 Aug.- -14 Sept.	"Johan Hjort"	As above.
5a	16 Sept.- -7 Oct.	"G.O. Sars"	Distribution, quantity, age and size composition of capelin before the winter fishery.
5b	16 Sept.- -7 Oct.	"Johan Hjort"	As above.
