REPORT OF THE SAITHE (COALFISH) WORKING GROUP

Charlottenlund, 14-18 February 1977

This Report has not yet been approved by the International Council for the Exploration of the Sea; it has therefore at present the status of an internal document and does not represent an advice given on behalf of the Council. The proviso that it shall not be cited without the consent of the Council should be strictly observed.

x) General Secretary,
ICES,
Charlottenlund Slot,

Report of the Saithe (Coalfish) Working Group

1. Participants

B Fontaine	France
K Hoydal	Denmark (Faroe Islands)
T Jakobsen (Chairman)	Norway
J Janusz	Poland
B W Jones	United Kingdom (England)
H Knudsen	Denmark
S Munch Petersen	Denmark
S Myklevoll	Norway
H H Reinsch	Germany, Fed. Rep. of
J Richards	United Kingdom (Scotland)
S A Schopka	Iceland
B Vaske	German Democratic Republic

ICES Statistician, Dr V M Nikolaev, also participated in the meeting.

2. Terms of Reference

At the 64th Statutory Meeting of ICES it was decided (C.Res.1976/2:27) that:

"the Saithe (Coalfish) Working Group should meet at Charlottenlund from 14-18 February 1977 to assess TACs for 1978".

In addition, following the NEAFC request from the November 1976 Mid-term Meeting, the Working Group was requested by the Chairman of the Liaison Committee of ICES to provide a description of life histories, fisheries and distributions of the stocks in relation to zones under national fisheries jurisdiction for Saithe, Dogfishes and Sharks in the ICES Area.

In an understanding with the Chairman of the North Sea Roundfish Working Group Pollack was also included in the additional terms of reference.

3. Landings

Since the last meeting of the Working Group, Denmark had made estimates of landings of saithe taken as by-catches in the industrial trawl fisheries in the North Sea. These estimates, together with revised data for landings from fisheries for human consumption, were as follows:

Year	Industrial fisheries	Human consumption fisheries	Total
1970	58 700	4 600	63 300
1971	34 700	11 500	46 200
1972	22 600	17 000	39 600
1973	24 400	10 100	34 500
1974	38 800	8 300	47 100
1975	27 800	10 200	38 000
1976	53 594	12 479	66 073

The landings from the industrial fisheries had not previously been included in the North Sea landings but have now been included in Tables 1 and 3.

Tables 2-6 give landings for 1966-75 and provisional data for 1976. Catches at Iceland have continued to decline due to the lower level of recruitment in recent years. In the other areas the 1973 year class appears to be very abundant and is now making an important contribution to the catches.

4. Virtual Population Analysis (VPA)

Assessments made at the previous meeting of the Working Group (ICES, Doc. C.M.1976/F:2) have been updated using provisional age composition data for 1976 with revisions, where appropriate, to the data for earlier years. The Group experienced some difficulty in preparing age compositions for the North Sea. For this area, no U.S.S.R. age composition data were available for 1976 landings which accounted for one-third (106 000 tons) of the total catch. The summed age compositions for other countries (excluding the Danish industrial catch) were raised to allow for U.S.S.R. landings. In addition, there were revisions to the Danish landings as described in Section 3. An age composition for landings from the Danish industrial fishery was available only for 1976 and consisted of fish of ages 2-4, with 3 year olds of the apparently very abundant 1973 year class predominating. For earlier years the Group considered that the best approximation would be to assume that the Danish industrial landings were composed of the same three age groups, and age compositions were generated for this fishery assuming that the relative abundance of the age groups would be the same as in U.S.S.R. landings. The resultant age compositions used as input data are given in Table 10 and corresponding data for the other areas are shown in Tables 7, 13, 16 and 19.

Estimates of fishing mortality are given in Tables 8, 11, 14, 17 and 20. These tabulations also show the values of F assumed for 1976 which were used to initiate the computation. These latter values have been based on what is known about recent trends in the fishery. For the North Sea the inclusion of Danish industrial landings created problems in estimating input values of F for 1976 for the younger age groups. The values of F assumed for the younger age groups directly influence the estimates of the abundance of the year classes most recently recruited to the fishery. The assumed value of F for 3 year olds in 1976 results in a very large estimate for the 1973 year class in the North Sea. All the indications are that this is a very abundant year class but no independent estimates of year class strength were available for comparison.

Stock size estimates from VPA are given in Tables 9, 12, 15, 18 and 21. Year class strengths at 2 years old are tabulated in Table 28. The natural mortality coefficient, M, has been taken as 0.2 throughout.

5. The State of the Stocks

5.1 North-East Arctic

Fishing mortality appears to have remained relatively stable over recent years at about $F = 0.4$ on age groups 4 and older but with a higher $F (= 0.5)$ on 3 year olds. The 1973 year class is an abundant one, especially in the southern part of the area where they have been exploited as 2 and 3 year old fish in the purse-seine fisheries. Recent tagging experiments on young saithe on the Norway coast between 62°N and 65°N have given a high proportion of recaptures south of 62°N , i.e. in the North Sea statistical area.

5.2 North Sea

Problems relating to the North Sea assessment have been described above. The overall level of fishing mortality is believed to have remained relatively constant. The Danish industrial fishery by-catch in 1976 contained mainly 3 year old fish and the increase in the landings from this fishery in 1976 is likely to reflect the abundance of the 1973 year class rather than increased fishing effort as the fishery is not directed towards saithe. There were no data available to suggest that the total fishing on 3 year old fish had increased substantially in 1976 and the F values assumed for 1976 were set at a level comparable with values estimated for the preceding years using trial VPA runs. The resultant estimate of 2 year old year class strength for the 1973 year class was 934 million which is approximately double the previous largest year class.

5.3 Iceland

Again there appears to have been no major change in this fishery and fishing mortality on the fully exploited age groups is $F = 0.5$, which is slightly below the MSY level ($F = 0.55$). Year classes of 1969 and later have been less abundant than those of 1960-68, and there is no indication of any abundant year classes among those now recruiting to the fishery.

5.4 Faroe

Fishing mortality was probably at a somewhat lower level in 1976 as a result of reduced fishing by French vessels and this is likely to have reduced the fishing mortality rates on the 4 and 5 year old fish in particular.

With the current exploitation pattern, fishing mortality ($F = 0.4$) appears to be slightly below the level required to give maximum sustainable yield ($F_{MSY} = 0.5$). As in most of the other areas the 1973 year class appears to be an abundant one.

5.5 West of Scotland

Data for this fishery are less good than for the other areas. No age composition data are available for the French fishery which accounts for about two thirds of the landings. The English age compositions are used for all countries except Scotland for which separate data are available. In this area also the 1973 year class appears to be very abundant and has contributed to the increase of catch in 1976.

6. Estimation of Total Allowable Catches (TACs)

Catch prognoses have been prepared for the years 1977-79, using the data given in Tables 22-26. Average (1963-72 year classes) year class strengths have been used for the recruiting year classes for the North-East Arctic, Faroe and West of Scotland. For the North Sea, the average recruitment was determined from year classes 1962-71. For Iceland, recent year classes have been less abundant than in earlier years and prognoses have been based on recruitment averaged for year classes 1968-72. Weight at age data have been adjusted in some cases so that the sum of 1976 catch numbers x average weight gives agreement with the 1976 landed weight. In all the prognoses, except at Iceland, it has been assumed that the exploitation pattern will remain unchanged. In at least some of the areas this may not be a realistic assumption. Changes in the relative amounts of fishing by countries involved in the fisheries which may follow the change to coastal state jurisdiction could for example affect the exploitation pattern.

For all stocks it was assumed that fishing mortality in 1977 would continue at the 1976 level. For 1978 and 1979 prognoses were prepared on the basis of (a) fishing mortality remaining constant at the 1976 level and (b) fishing mortality reducing over two years to F_{MSY} if the 1976 level F exceeded F_{MSY} . The fishing mortality giving maximum sustainable yield (MSY) was obtained from the yield curves in Figure 1. These were calculated on the model in which F varies with age as described in ICES Doc. C.M.1976/F:2. The results of the prognoses are given in Table 27.

6.1 Recommendations for Total Allowable Catches (TACs)

6.1.1 North-East Arctic

In this area the level of fishing mortality is above F_{MSY} for the present exploitation pattern. The maximum mortality is experienced by three year old fish. Spawning stock biomass is becoming reduced. The Group recommends that consideration be given to reducing fishing mortality either by an overall reduction in the amount of fishing, or, what is probably preferable, by reducing fishing mortality on the younger age groups and increasing the average age at first capture. For example, by preventing capture of 2 and 3 year old fish the long-term yield could be increased by 30%. If an overall reduction in fishing were to be adopted, the TAC for 1978 would be 108 000 tons if a change to F_{MSY} was to be made in one step. This would involve a severe reduction in catches which could be lessened if F was reduced in two stages, e.g., $F = 0.4$ in 1978 and $F = 0.25$ in 1979. In this case the TAC for 1978 would be 163 000 tons. Fishing at F_{MSY} would be expected to give an average equilibrium yield of 204 000 tons (average number one year old recruits x yield per one year old recruits).

6.1.2 North Sea

As for the North-East Arctic the current fishing mortality rate is above F_{MSY} and the three and four year old fish are suffering higher mortality rates than the older age groups. In this area a large proportion of the young fish mortality is generated by industrial fisheries for other species. Again there is a need to reduce fishing mortality overall to at least F_{MSY} or to give protection to younger age groups to increase the average age of first capture. Various regulatory measures relating to industrial fisheries are being considered for implementation in 1977 but their likely effects on the saithe by-catches are unpredictable. Another problem is the actual size of the 1973 year class which is currently estimated as a very large one. However, by 1978 this year class will be past making its main contribution to the catches. If an overall reduction in fishing mortality is considered this could be spread over two years reducing F to 0.42 in 1978 and 0.35 in 1979. For this strategy the Group recommends a TAC for 1978 of 224 000 tons. The North Sea assessment did not include data for Norwegian industrial landings, and to make allowance for landings taken in this fishery the TAC could be increased by about 5 000 tons.

6.1.3 Iceland

At Iceland the saithe stock is being fished close to the F_{MSY} level and the exploitation pattern is such that there is less fishing on the younger age groups than in other stocks. The new minimum trawl cod end mesh size of 155 mm introduced in 1977 can be expected to reduce fishing mortality on the younger age groups still further. The immediate loss resulting from the mesh change is expected to be about 4%. The catch prognoses have assumed a relatively low figure for the recruiting year classes which is more consistent with the recent recruitment levels than a longer-term average which would include year classes from the period

when recruitment was at a higher level. If the fishery is maintained at the current F level, and taking into account the effects of the increased mesh size at Iceland, a TAC of 64 000 tons is recommended for 1978.

6.1.4 Faroe

This stock is being exploited at slightly below the F_{MSY} level for the current exploitation pattern. Prognoses have been calculated on the basis of F continuing at the same ($F = 0.4$) level or for an increase to F_{MSY} (= 0.5) in 1978. For fishing at the MSY level in 1978 it is recommended that the TAC for 1978 should not exceed 45 000 tons.

6.1.5 West of Scotland

In this area the yield per recruit is low due to the high rate of exploitation on younger fish, and while this exploitation pattern is maintained the current levels of F are above those required for MSY. There is a need to reduce fishing mortality to about half the present level or alternatively protection should be given to the younger age groups. To reduce fishing mortality rate to the MSY level it is suggested that this could be done in two stages, reducing to $F = 0.45$ in 1978 and to $F_{MSY} = 0.3$ in 1979. For this strategy a TAC for 1978 of 20 000 tons is recommended.

6.2 Summary

The following TACs are recommended for 1978:

<u>Area</u>	<u>1978 TAC (in tons)</u>
North-East Arctic	163 000
North Sea	224 000 ¹⁾
Iceland	64 000
Faroe	45 000
West of Scotland	20 000

1) Does not include any allowance for Norwegian industrial landings.

For the areas where a reduction in fishing mortality has been recommended the average equilibrium yields have been calculated for fishing mortality rates at the present and the MSY levels:

	<u>Equilibrium Yield</u>	
	<u>Present F</u>	<u>F_{MSY}</u>
North-East Arctic	182 000 tons	204 000 tons
North Sea	180 000 tons	186 000 tons
West of Scotland	19 000 tons	20 000 tons

The fishing mortality levels corresponding to F_{0.1} are close to $F = 0.2$ for all areas.

7. Spawning Stock Biomass

In Table 29 the calculated spawning stock biomass for each stock is given for the period 1960-77. For all stocks there has been a considerable

decline during the last five years.* However, only in the North-East Arctic has the spawning stock biomass been reduced to a level below what has previously been recorded. The rate of decline has apparently been high and this is supported by claims from Norwegian gill-net fishermen that catch per effort of spawning saithe in the Svinøy area has been severely reduced in recent years. For the other stocks, rich year classes have previously been produced at or below the present spawning stock biomass level.

* This is at least partially due to lower levels of recruitment in recent years.

Table 1. Summary of total landings of saithe from the main fishing areas (metric tons, whole weight). This table is based on the biological data supplied to the Working Group and used in the assessments. These figures differ to some extent from the official "Bulletin Statistique" data, which are used for Tables 3-7.

Year	Fishing area					Total
	NE-Arctic	IV+IIIa	Va	Vb	VI	
1960	136 006	31 515	48 120	11 845	8 349	235 835

1) Fishing mortality on age groups subject to maximum exploitation.

Table 28. Estimates from Virtual Population Analysis
of population size (millions) at 2 years old
of each year class. (Estimates of year class
size of the most recent year classes are less
reliable.)

Year class	NE-Arctic	North Sea	Iceland	Faroe	Scotland
1958	116	38	41	10	8
1959	229	35	39	15	9
1960	337	50	103	25	18
1961	117	67	68	18	15
1962	361	163	115	26	29
1963	204	118	87	23	20
1964	247	165	82	28	17
1965	186	134	72	22	26
1966	365	366	108	42	20
