REPORT OF THE SAITHE (COALFISH) WORKING GROUP

Copenhagen, 20-27 April 1982

This document is a report of a Working Group of the International Council for the Exploration of the Sea and does not necessarily represent the views of the Council. Therefore, it should not be quoted without consultation with the General Secretary.

x) General Secretary,
ICES,
Palægade 2-4,
DK-1261 Copenhagen K,
Denmark.

REPORT OF THE SAITHE (COALFISH) WORKING GROUP

1. PARTICIPANTS

R M Cook	United Kingdom (Scotland)
H Gislason	Denmark
T Jakobsen (Chairman)	Norway
S H f Jakupsstovu	Faroës
B W Jones	United Kingdom (England)
J B Pérodou	France
H H Reinsch	Federal Republic of Germany
S A Schopka	Iceland

K Hoydal attended the meeting as the ICES Statistician.

2. TERMS OF REFERENCE

At the 69th Statutory Meeting it was decided (C.Res.1981/2:27:5) that the Saithe (Coalfish) Working Group should meet at ICES headquarters 20-27 April 1982 to:

- (i) assess catch options for saithe stocks in 1983, taking into account possible relationships between the North Sea stock and the North-East Arctic stock,
- (ii) assess catch options for cod and haddock in the Faroes area,
- (iii) advise on appropriate mesh sizes for saithe for trawl gears in Sub-areas I and II and Sub-area IV,
- (iv) specify deficiencies in data required for assessments.

3. LANDINGS IN THE NORTH-EAST ATLANTIC

From 1970 to 1976 the total landings of saithe from the main fishery areas in the North-East Atlantic were in the range of 640 000 - 720 000 tonnes (Table 3.1). In subsequent years, landings have declined to a level of about 400 000 tonnes. Preliminary reported landings in 1981 are 410 000 tonnes.

4. NORTH-EAST ARCTIC SAITHE

4.1 Landings (Table 4.1, Figure 4.1.A)

The provisional estimate of landings in 1981 was 172 000 tonnes, which was an increase from 145 000 tonnes reported for 1980. Landings in 1981 were significantly in excess of the TAC of 123 000 tonnes recommended for that year. The increased landings were due mainly to Norwegian trawlers.

4.2 Age Composition (Table 4.2)

Revised age composition data submitted for 1980 resulted in significant changes from the provisional data used for this year in last year's assessment. Provisional data for 1981 were available for landings by the Federal Republic of Germany and Norway, which together accounted for almost 100% of total landings.

4.3 Weight at Age (Table 4.3)

Weight at age data for Norwegian landings were available for 1980 and 1981. For weight at age in the stock, data based on an average of Norwegian data for the years 1974-79 were used for 1980 and 1981 for stock biomass calculations.

4.4 Fishing Mortality and Stock Size Estimate from VPA

4.4.1 Estimates of fishing mortality (Table 4.4)

Values of F for 1981 used as VPA input were based on estimates of trends in the amount of fishing by the various fleets comprising the Norwegian fishery. The purse-seine fishery appears to have continued in 1981 in a manner similar to 1980 with a reduced fishing mortality on 2 year old fish. This fleet has been concentrating to some extent in 1981 on the relatively abundant 1978 year class, resulting in a higher F on 3 year olds in 1981.

It would appear that the values used last year as input for 1980 were too low and gave an overoptimistic estimate of the stock size. Input values of F on the oldest age group for the years 1977-80 have also been revised upwards to values which are more consistent with the VPA calculated values.

This year the Working Group re-considered the age range over which average fishing mortality is calculated, and agreed that the use of age groups 3 to 8 would be more appropriate for an index of fishing mortality than the ages 5 to 10, which were used previously. Indices of average fishing mortality quoted in this report are, therefore, not directly comparable with those given in last year's report.

The trend in fishing mortality is plotted in Figure 4.1.D. After the high levels recorded in 1974-76, the fishing mortality rates appear to have been reducing.

4.4.2 Spawning stock biomass and recruitment

Estimates of spawning stock biomass are given in Table 4.5 and Figure 4.1.B. Higher input F values for 1981 than were used last year for 1980, and an upwards revision of F on the oldest age groups in recent years have resulted in spawning stock biomass estimates for the recent period being considerably lower than last year's estimates. Spawning stock biomass has been falling continuously since 1970 and is associated with the increased fishing mortality from 1968-76. The spawning stock should benefit from the reduction in fishing mortality since 1976, and an improvement is expected in the prediction period.

Estimates of stock numbers at each age are given in Table 4.5, and recruitment at age 1 is plotted in Figure 4.1.C. No clear trend in recruitment is apparent.

4.5 Yield per Recruit

The yield per recruit curve given in Figure 4.2 has been calculated using the exploitation pattern and weight at age data for the stock given in Table 4.6. The present level of $F = 0.36$ (\bar{F}_{3-8} unweighted) is in excess of $\bar{F}_{\max} = 0.26$ and $\bar{F}_{0.1} = 0.16$.

4.6 Catch Predictions

The data used in the catch predictions are given in Table 4.6. Average recruitment (average 1966-78) has been assumed for the year classes 1980-83. It has further been assumed that fishing mortality

in 1982 will remain at the 1981 level of $\bar{F}_{3-8} = 0.36$. Predicted catches and stock biomasses for 1982 and for a range of levels of fishing mortality in 1983 are given in Table 4.7. Predicted landings in 1983 and spawning stock biomass estimates for the beginning of 1984 are presented graphically in Figure 4.3. For the assumption that F remains unchanged at the 1981 level, landings in 1982 are expected to be 155 000 tonnes, which is 17 000 tonnes lower than in 1981, but they are expected to increase again to 170 000 tonnes in 1983.

5. NORTH SEA SAITHE

5.1 Landings (Table 5.1, Figure 5.1.A)

The reported landings for 1981 were 123 847 tonnes, a figure close to the 123 446 tonnes reported for 1980. The TAC in 1981 was 127 000 tonnes.

5.2 Age Composition (Table 5.2)

The age composition for 1980 was updated. The main difference between the age composition for 1980 used last year and the one given in Table 5.2 was due to a revision of the age composition of the Norwegian landings. The sums of products in 1980 were 8% below the reported landings.

For 1981 a provisional age composition was constructed, based on data from Denmark, England, Federal Republic of Germany, France, Norway and Scotland. The landings of these countries represented 99% of the reported landings. The SOP was 82 tonnes above the nominal landings.

As in previous years the age composition was derived by raising the sum of the reported age compositions in the human consumption fishery to the total landings from this fishery. The total age composition was subsequently calculated by adding the age composition of the industrial landings.

5.3 Weight at Age (Table 5.3)

Weight at age data from Denmark, England, France, Norway and Scotland were used to calculate a set of weight at age data for 1980 and 1981. Annual averages weighted by catch in numbers were calculated and used for weight at age in the catch and stock.

For predictions, the average of the weight at age in 1979-81 were used. (Table 5.7.)

5.4 Fishing Mortality and Stock Values from VPA

5.4.1 Estimates of fishing mortality

A trial VPA, using the same terminal F values as last year, showed no changes in the average fishing mortality for ages 3-6 between 1980 and 1981. However, the average fishing mortality at age for 1977 and 1978 showed a peak for ages 4 to 6, and a new exploitation pattern was, therefore, calculated, assuming ages 7 and older to be equally exploited.

French effort data were used to calculate the effort of the total international fleet by dividing total landings by the French catch per unit of effort (Table 5.6). The total effort shows no major change from 1980 to 1981.

A second VPA with the new exploitation pattern and \bar{F}_{3-6} equal to 0.37 in 1981 showed little change in the average fishing mortality

from 1978 to 1981, and a decline from 1976-78 which was reasonably consistent with the effort data and was therefore adopted by the Working Group. The terminal fishing mortality at age 1 was chosen in order to give a recruitment of 200 million fish in 1981. This recruitment is above the average recruitment in the years 1975-79 and was chosen because of the large catch of 1 year old fish in 1981.

This year the Working Group re-considered the age range over which average fishing mortality is calculated and agreed that the use of age groups 3 to 6 would be more appropriate for an index of fishing mortality than the ages 5 to 10, which were used previously. Indices of average fishing mortality quoted in this report are, therefore, not directly comparable with those given in last year's report.

The trend in fishing mortality is plotted in Figure 5.1.D.

5.4.2

Spawning stock biomass and recruitment

Spawning stock biomass (Table 5.5 and Figure 5.1.B) has fluctuated since 1976 between 270 000 tonnes and 335 000 tonnes. Figure 5.1.C shows recruitment at age 1. The year classes 1975-78 appear to be below the long-term average. In the predictions, the recruitment in 1982 to 1984 was assumed to be equal to the average recruitment of the year classes 1975 to 1978 ($R_1 = 148 \times 10^6$).

5.5

Yield per Recruit

The yield per recruit curve (Figure 5.2) was calculated using the average weight at age in the years 1979-81 and the current exploitation pattern (Table 5.7). F_{max} expressed as the average fishing mortality for ages 3-6 is 0.26. The present fishing mortality is estimated to be $\bar{F}_{(3-6)} = 0.37$.

5.6

Catch Predictions

Table 5.7 shows the input data used in the catch predictions. The agreed TAC for the North Sea in 1982 is 125 000 tonnes, and the predicted catch is 124 000 tonnes. The results of the catch predictions are shown in Table 5.8 and Figure 5.3 for a range of options for 1983.

6.

ICELANDIC SAITHE

6.1

Landings

Landings of saithe from Division Va are shown in Figure 6.1.A and in Table 6.1. Since 1977, catches have been at a fairly stable level of 50 000 - 60 000 tonnes annually. Landings in 1981 were 59 000 tonnes.

6.2

Age Composition

Age composition data were available only for the Icelandic catches which accounted for 93% of the total landings in 1981. The total catch in numbers used as input for the VPA (Table 6.2) was calculated by raising the other catches with the Icelandic age composition data. The 1980 data were revised and updated.

6.3

Weight at Age

Weight at age data used for stock biomass calculations are given in Table 6.3. In 1979, several thousand specimens of saithe were measured and weighed, and the length/weight relationship was revised. The 1979 weight at age data were used for the period 1974-79, when the sum of products estimates were within 2% of the actual landings. In the period 1966-73, data from previous assessments were used unchanged.

Since 1979 the average weight at age has been declining. An average of the 1980 and 1981 data were used in the catch projections (Table 6.6).

6.4

Fishing Mortality and Stock Values from VPA

6.4.1

Estimates of fishing mortality (Table 6.4)

The big increase in redfish catches in 1981 implies that some effort was diverted from the saithe fishery. Therefore, the average of the relatively stable F values in the 1977-79 period, which were somewhat lower than the 1980 F values, have been used as input F for the VPA. The unweighted mean fishing mortality on the age groups 4-9 which accounts on average for about 90% of the catches, has been taken as a reference fishing mortality in the presentation of the assessments (Figure 6.1.D).

6.4.2

Spawning stock biomass and recruitment

Spawning stock biomasses are shown in Figure 6.1.B and Table 6.5. The spawning stock biomass increased from 122 000 tonnes in the early 1960s to a peak of 443 000 tonnes in 1969. This increase in spawning stock biomass was the result of higher year class strengths. Since 1969 the spawning stock has been declining, and in 1981 (174 000 tonnes) it was at a level similar to that in the mid-1960s.

The 1960-67 year classes were more abundant than the 1968-77 year classes (Figure 6.1.C and Table 6.5). The abundance of the 1979 year class at age 2 was assumed to be 42 million fish equal to the average for the year classes 1968-77. Accordingly, the input F for this year class at age 3 in 1980 was adjusted to produce this result. For the catch projections, abundances for 1980 and 1981 were also assumed to be 42 million fish (35 million at age 3).

6.5

Yield per Recruit

The yield and spawning stock biomass per recruit curves are shown in Figure 6.2. No changes in the exploitation pattern have taken place in recent years and, therefore, the average 1977-79 exploitation pattern has been used. The yield per recruit curve is flat-topped. F_{max} is about 0.39, and the present fishing mortality on age groups 4-9 is estimated to be $\bar{F}_{(4-9)} = 0.29$.

6.6

Catch Predictions

The input data for catch projections are shown in Table 6.6. The projections are based on the 1977-79 exploitation pattern also used as input to the VPA.

The recommended TAC for 1982 is 62 000 tonnes. Assuming the same effort on saithe in 1982 as in 1981, the expected catch in 1982 will be 67 000 tonnes. The associated spawning stock biomass in 1983 will be 184 000, and the total stock biomass about 350 000 tonnes. The results of catch projections for 1983 and total stock and spawning stock biomasses in 1984 are given in Table 6.7 and Figure 6.3.

7. FAROE SAITHE

7.1 Landings and Changes in the Fisheries

Preliminary catch data indicate a total catch of 30 176 tonnes from the Faroe saithe stock in 1981 (Table 7.1, Figure 7.1.A). This is an increase by 4 946 tonnes compared to 1980. Foreign catches were very small in 1981 compared to previous years and constituted only 1.7% of the total catch in 1981. The Faroese catch increased by 5 866 tonnes in 1981.

7.2 Age Composition (Table 7.2)

Age compositions for 1981 were available only for the Faroese landings. The Federal Republic of Germany and France landings were distributed according to age distributions of catches by Faroese trawlers more than 1 000 HP. The Norwegian catch at age was estimated from Faroese gill net catch at age compositions. The United Kingdom (Scotland) landings were distributed using the age composition in the Faroese trawlers, less than 1 000 HP, landings.

7.3 Weight at Age (Table 7.3)

The weight at age data set used by the 1981 Working Group were used for the years previous to 1981. Weight at age data were provided for the Faroese landings in 1981. These, however, gave a high sum of products discrepancy, and the Working Group, therefore, decided to use for 1981 the mean weights at age for the period 1978-80. These values were also used for the catch predictions.

7.4 Fishing Mortality and Stock Values from VPA

7.4.1 Estimates of fishing mortality (Table 7.4)

The fishing pattern for saithe by the Faroese fleet in 1981 was in general similar to that in 1979 and 1980, with a fishery from October to April on adult fish aggregating on the spawning grounds, and another fishery during summer in shallower water exploiting mainly younger fish.

The development, which started in 1980 with smaller trawlers (less than 1 000 HP) trawling as pair trawlers rather than as single boat trawlers, has continued in 1981 with the result that a significant part of this size group and also medium-sized trawlers are now operating as pair trawlers. One of the benefits obtained with this strategy is that the boats, when operating as pair trawlers, can fish in deeper water compared to operating as single boat trawlers.

As in 1980, the smaller pair trawlers in 1981 exploited mainly young fish. This was also the case for the smaller single boat trawlers in 1981. The age composition of the landings from the larger pair trawlers and the larger single boat trawlers was more evenly distributed over the whole age range. A special feature for the whole trawler fleet is occasional, large catches of young saithe throughout the year.

Compared to 1980, the total effort of the Faroese fleet mainly fishing for saithe in 1981 was on the same level. The change towards pair trawling and the reduced effort used in the redfish fisheries, however, have probably increased the directed effort on the saithe to some extent in 1981.

Trial VPA runs, using the same input F's as were used by the 1981 Working Group, showed that the assumptions, on which the assessments in 1980 and 1981 were based, i.e. that the fishing pressure was higher on the younger age groups (4-6 years old) than on the older age groups, were not valid. Using this assumption, the trial VPA runs also indicated more than 50% increase of the fishing mortality on the 4-8 year olds in 1981 compared to 1980. This increase in effort was not evident from the Faroese effort data brought to the meeting. The available evidence, therefore, indicates the following:

- 1) F on young fish (4-6 years) in 1981 is less than F on old fish (7+) in 1981,
- 2) F on young fish in 1981 is greater than F on young fish in 1980,
- 3) F on old fish in 1981 is greater than F on old fish in 1980.

The set of input F values for 1981 chosen by the Working Group was 0.18 for the ages 4-6, and 0.27 for older ages. These values allow the three conditions mentioned above to be satisfied. This could also be achieved by higher levels of F, but this would increase the discrepancy with the effort data. The VPA results are given in Tables 7.3 and 7.4.

This year the Working Group re-considered the age range over which average fishing mortality is calculated and agreed that the use of age groups 4 to 8 would be more appropriate for an index of fishing mortality than the ages 5 to 10, which were used previously. Indices of average fishing mortality quoted in this report are, therefore not directly comparable with those given in last year's report.

7.4.2 Spawning stock biomass and recruitment (Table 7.5)

The change in assumptions of the exploitation pattern and also the revision of some input F values on the oldest age groups have resulted in estimates of spawning stock biomasses for the recent years, which are larger than those given in last year's report (Figure 7.1.B).

No independent estimate is available for the strengths of recruiting year classes. From the VPA, the recruitment appears to have varied extensively, with recruitment of 1 year olds between 20 and 40 millions in the period 1961-66, between 50 and 70 millions in the period 1967-70, and between 20 and 40 millions again in the period 1971-78, except for the year class 1976, which is somewhat lower (Figure 7.1.C). The assumption that the 1978 year class is above average year class strength, for the most recent years, is not evident from the VPA done this year. With the exploitation pattern assumed now, however, the year class is not fully recruited to the fishery yet.

7.5 Yield per Recruit

Curves of yield per 1 year old recruit and spawning stock biomass per recruit are also plotted in Figure 7.2. Fishing mortality in 1981 ($\bar{F}_{4-8} = 0.22$) is less than $F_{\max} = 0.44$. For a constant average recruitment (1974-77 year classes) of 21.2 million 1 year olds, the equilibrium yield with the 1981 exploitation pattern would be 22 000 tonnes, and the corresponding spawning stock biomass 93 000 tonnes.

7.6

Catch Predictions

Input data for the catch predictions are given in Table 7.6. The year classes 1978 onwards are assumed to be the average of the 1974-77 year classes ($R_1 = 21.2 \times 10^6$). In Table 7.7 the yield in 1983 and the spawning stock biomasses for 1984 are given under different assumptions of fishing mortality in 1983, on the basis that fishing mortality in 1982 is unchanged from the 1981 level.

8.

WEST OF SCOTLAND SAITHE

8.1

Landings

Landings of saithe from Sub-area VI are shown in Figure 8.1.A and in Table 8.1. The TAC for 1981 was 27 000 tonnes, while landings were 24 000 tonnes.

8.2

Age Composition (Table 8.2)

Revised data for 1980 and preliminary data for 1981 were available from the United Kingdom (England and Wales), United Kingdom (Scotland), and France. These accounted for 97% of the 1980 landings and 95% of the 1981 landings (Table 8.1). The combined landings of these nations were raised to the total international catch.

8.3

Weight at Age (Table 8.3)

Mean weight at age values used in making predictions are shown in Table 8.7. These are the weighted means for the years 1979-81 and are similar to the values used by the 1981 Working Group.

Sum of products discrepancies for each national data set in 1980 and 1981 were less than 7%. Scottish and French numbers at age were adjusted to compensate for these discrepancies. For the English data, mean weight at age was adjusted.

8.4

Fishing Mortality and Stock Values from VPA

8.4.1

Estimates of fishing mortality

Table 8.6 shows the estimation of fishing effort relative to 1981. These data indicate a similar effort in 1981 compared to 1980. On this basis, input F_s were chosen at the same level as those used for 1980. This results in lower F_s in 1980, but is consistent with the difference in the landings for the same period. The plot of relative effort versus relative F (Figure 8.2) indicates that mean $F(3-6)$ in 1981 is also consistent with the historical data set.

The Working Group felt that the mean F calculated over ages 3-6 best reflected the fishing mortality level on the stock. Using the same exploitation pattern as the historical mean, F_s were therefore selected which gave $\bar{F}(3-6) = 0.20$, the same as the value used for 1980 by the 1981 Working Group.

8.4.2

Spawning stock biomass and recruitment

Historical spawning stock biomass figures are shown in Table 8.5 and Figure 8.1.B. The estimated spawning stocks for the years 1979-81 are all similar. In view of the higher weights at age used in these years and the unreliability of earlier weight at age data, these spawning stocks are probably relatively lower than Table 8.5 suggests.

The estimated number of recruits at age 1 are shown in Table 8.5 and Figure 8.1.C.

No data are available for Sub-area VI to assess the abundance of recent year classes. In view of the continuing lower recruitment estimated in recent years, an average for the years 1975-79 was used to give an estimate of 28 millions for the 1980 year class. The same value was used for the 1982-84 prediction runs.

8.5

Yield and Spawning Stock Biomass per Recruit

The yield and spawning stock biomass per recruit curves are shown in Figure 8.3. The yield/recruit curve is flat-topped. The present estimated level of fishing mortality, $\bar{F}_{(3-6)} = 0.2$, approximates to $F_{0.1} = 0.2$ and is well below $F_{\max} = 0.32$.

8.6

Catch Predictions

Input data for catch predictions are shown in Table 8.7. It was assumed that \bar{F}_{3-6} in 1982 = \bar{F}_{3-6} in 1981. The results are shown in Table 8.8 and Figure 8.4.

9.

FAROE COD

9.1

Faroe Plateau Cod

9.1.1

Landings and fishing effort

Landings in 1981 were 23 000 tonnes compared to 21 000 tonnes in 1980 (Table 9.1 and Figure 9.1.A). In 1980, 98% of the total landings were made by Faroese vessels. Records of fishing effort show that compared with 1979 and 1981, effort was less for several of the vessel categories fishing mainly for cod. For two new vessel categories smaller (less than 1 000 HP) and larger (greater than 1 000 HP) pair trawlers, the effort was significantly higher in 1981 compared to 1980. Although these vessels fish mainly saithe, cod and haddock constitute approximately 25% of their total landings. Several of the long-liners and smaller trawlers in 1980 and 1981 directed their effort towards cod for only a part of the year. A small overall reduction in fishing since 1979 is likely to have been the net result.

9.1.2

Age composition (Table 9.3)

Age compositions were provided only for the Faroese landings. The French landings were distributed according to age distribution of catches by the larger Faroese trawlers (more than 1 000 HP). The Norwegian and United Kingdom (Scotland) catch at age was estimated using the age composition in the larger Faroese long-liners' landings.

Again in 1981, larger than normal landings were reported to have been taken in the Faroes area by vessels of the Federal Republic of Germany. It was again assumed by the Working Group that these fish were incorrectly attributed to Division Vb, and they were accordingly excluded from the data used in the assessments.

9.1.3

Weight at age (Table 9.4)

The weight at age data set used by the 1981 Working Group was used for the years prior to 1981. For the 1981 landings, weight at age from the Faroese catches was used and sums of products were within 4% of nominal landed weights. For the earlier years, discrepancies up to 20% were observed, but these will not significantly affect

the interpretation of the temporal trend in spawning stock biomass. Weight at age data used in catch predictions were an average for the years 1979-81.

9.1.4 Fishing mortality in 1981

Data for the Faroese catch in number by age group per unit effort for the smaller Faroese long-liners, which direct their effort mainly towards cod and haddock, were analysed, but the results were inconclusive. Estimates of F at age in 1981 were chosen by the Working Group to simulate the same fishing effort in 1981 as in 1980 (see para. 9.1.1).

9.1.5 Results of VPA (Tables 9.5 and 9.6)

9.1.5.1 Fishing mortality

Estimates of fishing mortality in each year, calculated from VPA, are given in Table 9.5, together with input values for 1981 and for the oldest age group in each year.

9.1.5.2 Spawning stock biomass and recruitment

Estimates of spawning stock biomass (age groups 4 to 10+) are given in Table 9.6 and shown graphically in Figure 9.1.B. Spawning stock biomass reached the maximum recorded level in 1977, when the very abundant 1972 and 1973 year classes had both been recruited to the adult stock. Since then, spawning stock biomass has declined.

The estimated number of recruits at age 1 for the year classes 1960-79 are given in Figure 9.1.C. Estimates of year class strength from 0-group surveys are not sufficiently reliable to predict the abundance of recruiting year classes and, therefore, year classes 1980-82 have been assumed to be equal to the average calculated for year classes 1965-77 (22 millions). The 1979 year class appears from the VPA to be of average strength, and the value estimated by VPA has therefore been used in the predictions. It was indicated by the 1981 Working Group that the 1978 year class was probably abundant. The assessment made in 1982 indicates that it is of the same order of magnitude as the very abundant 1972 and 1973 year classes.

9.1.6 Yield per recruit

Curves of yield and spawning stock biomass per 1 year old recruit are plotted in Figure 9.2, using the data given in Table 9.7. Fishing mortality in 1981 ($\bar{F}_{3-6} = 0.31$) is slightly in excess of $F_{\max} = 0.26$. For a constant average recruitment of 22 million 1 year olds, the equilibrium yield with the 1981 exploitation pattern would be 25 000 tonnes, and the corresponding spawning stock biomass would be 76 000 tonnes.

9.1.7 Catch predictions

Data used in the catch predictions are given in Table 9.7, and the results are given in Table 9.8 and plotted graphically in Figure 9.3. If fishing mortality in 1982 is maintained at the 1981 level ($\bar{F}_{3-6} = 0.31$), landings of 25 500 tonnes are predicted.

9.2 Faroe Bank (Table 9.2)

Landings of cod from the Faroe Bank have declined in recent years, and amounted to 1 000 tonnes in 1981. No attempt was made to assess this stock.

10. FAROE HADDOCK

The assessment was made for the stock of haddock for the total Faroe (Division Vb) area.

10.1 Landings and Fishing Effort

Landings in 1981 declined to the very low level of 12 100 tonnes compared to 15 000 tonnes in 1980 (Tables 10.1 and 10.2 and Figure 10.1.A).

Fishing effort data were available for the Faroese fleets. These indicated a slight reduction in effort by all the fleets, which traditionally land the bulk of the haddock catches (see also Section 9.1).

10.2 Age Composition (Table 10.3)

Age composition for the Faroese landings from the Faroe plateau were provided. These were used to calculate the age composition for the total landings from the Faroe plateau and Faroe Bank combined.

10.3 Weight at Age (Table 10.4)

The weight at age data set used by the 1981 Working Group was used for the years prior to 1981. Weight at age data for the 1981 catches were provided for the Faroese landings, but as these gave a large sum of products's discrepancy, the Working Group decided to use the mean for the years 1978-80, and these values were also used for the catch prediction.

10.4 Fishing Mortality

The available effort data indicated a slight reduction in the effort directed towards haddock in 1981 compared to 1980. Analysis of catch in number by age group per unit effort by the smaller long-liners supported this. As the reduction in effort, however, appeared to be small, the Working Group chose as input F's the same values as those used by the 1981 Working Group; this gave a fishing mortality level in 1981 similar to that in 1980.

10.5 Results of VPA

10.5.1 Fishing mortality

Estimates of fishing mortality in each year calculated by VPA are given in Table 10.5, together with input values for 1980 and for the oldest age group in each year.

10.5.2 Spawning stock biomass and recruitment

Estimates of spawning stock biomass (Table 10.6, Figure 10.1.B) were relatively stable at about 60 000 tonnes up to 1974. Subsequently, the spawning stock benefitted from the recruitment of the abundant 1972 and 1973 year classes, which increased the spawning stock to about 93 000 tonnes. By 1981, the spawning stock had returned to a lower level. The estimated numbers of recruits at age 1 are given in Table 10.5 and Figure 10.1.C. In recent years, the year classes of 1972-74 were the highest on record, but subsequently the recruitment declined and the 1977 year class appears to have failed almost completely.

In the predictions two different recruitment levels were assumed: Option 1: recruitment of 20 million 1 year olds consistent with the lower recruitment in recent years, and Option 2: recruitment of 39 million 1 year olds equal to the average recruitment in the years 1966-78.

10.6 Yield per Recruit

The yield per recruit curve given in Figure 10.2 has been calculated using the exploitation pattern assumed for 1981 and the mean weight at age for the years 1978-80.

The present level of $\bar{F}_{4-6} = 0.28$ is below $F_{\max} = 0.49$.

10.7 Catch Predictions

Table 10.7 shows the input data used in the catch predictions, and the results are given in Tables 10.8 and 10.9, and plotted graphically in Figure 10.3. If fishing mortality is maintained at the 1981 level ($\bar{F}_{4-6} = 0.28$), and assuming the lower recruitment level (Option 1), landings of 11 000 tonnes are predicted for 1982, and 10 300 tonnes for 1983.

11. OTHER STOCKS IN DIVISION Vb

Landing statistics for other species in Division Vb have been updated to include 1980 and are given in Tables 11.1 - 11.10.

12. APPROPRIATE MESH SIZES FOR SAITHE FOR TRAWL GEARS IN THE NORTH-EAST ARCTIC AND THE NORTH SEA

Calculations have been made to indicate the expected yield per recruit for a range of mesh sizes at different levels of fishing mortality. These show the relative yields that could be expected, if saithe in the two areas were fished only by trawl gears in a single species fishery. No account has been taken of gear interactions, if gears other than trawl are used, nor of any stock and recruitment effects or of possible density-dependent growth.

The method used is that described by Macer (ICES, C.M.1982/G:3). For a range of mesh sizes from 80 mm to 200 mm, exploitation patterns and weight at age data were calculated for each mesh size (Tables 12.1 and 12.2). Selectivity data were based on a selection factor of 3.79 (Hylen, 1969, and ICES Coop.Res.Rep., Ser.B, 1968), and the selection range was adjusted in proportion to mesh size. At the lower end of the length range with decreasing mesh size, the capture by trawl is increasingly determined by availability rather than by selection.

Using the calculated exploitation patterns and weights at age, yields per recruit were calculated for each mesh size for a range of levels of fishing mortality for the two areas (Tables 12.3 and 12.4). The values of F_{\max} on the yield per recruit curve for each mesh size are also given in the tables. In both tables, the F values indicated are those on 4 year old fish. The present equivalent F values generated by the human consumption trawl fisheries are 0.28 in the North-East Arctic and 0.38 in the North Sea. At these current levels of fishing mortality, the maximum yield per recruit would be obtained using mesh sizes of 160 mm in the North-East Arctic and 180 mm in the North Sea.

13. INTERRELATIONSHIPS BETWEEN DIVISION IIIA AND SUB-AREA IV

With regard to the interrelationships between Division IIIa and Sub-area IV, the Working Group considered a paper by Jakobsen (ICES, C.M.1981/G:36). The analysis made in this paper is likely to represent more accurately the assessments based on the North-East Arctic and North Sea stocks as opposed to the assessments made by the Working Group based on the North-East Arctic and North Sea statistical areas. However, it is difficult to use these stock assessments as a basis for management advice. With the present regulatory boundary at 62°N, and no change in the fisheries, catches of fish of the North Sea stock will be taken north of 62°N. A change of the boundary between regulatory areas to 64°N would result in catches of the North-East Arctic stock, particularly of the spawning stock, being taken south of 64°N.

If there is no change in the regulatory boundary and there is no change in the fisheries, the traditional area-based assessments provide the best basis for management advice. However, if there were any changes in the fisheries or the conservation regulations in the area 62-64°N where distributions of the two stocks overlap, then the movements of fish between the two areas could have management implications.

For example, in the 62-64°N area there are fisheries, which concentrate their activities on young fish. The result of these fisheries is that there is, in this area, a relatively high fishing mortality on young fish. Increased yield could be obtained by improving the exploitation pattern by reducing or stopping fishing on the younger age groups. However, results of tagging experiments have indicated that young fish in the area 62-64°N tend to migrate south of 62°N as they grow older. This would imply that if fishing on young fish in the area 62-64°N is reduced, the long-term gains are likely to accrue mainly to the North Sea fisheries south of 62°N. A complete cessation of fishing in the young-fish fisheries in the 62-64°N area would result in an annual loss of about 20 000 - 30 000 tonnes from the fisheries in Division IIIa (north of 62°N). If the survivors from these fisheries were subsequently available to capture only in the North Sea south of 62°N, an increase in North Sea catches of about 50 000 tonnes would be expected. This figure is based on the expected number of additional recruits to the North Sea and the yield per recruit being achieved at current North Sea levels of fishing mortality and with the current North Sea exploitation pattern.

14. DEFICIENCIES IN THE DATA REQUIRED FOR ASSESSMENTS

Age and length sampling of the stocks assessed in this report seem presently to be carried out at a satisfactory level. In all saithe stocks effort data have so far been of little use as a basis for estimates of fishing mortality. This is chiefly a result of the fact that saithe in many fisheries is not the main target species. In some cases, there are effort data that may be potentially useful, but the time series is too short. The prospects of improving the effort data generally seem poor, although some improvement may be achieved, if effort could in some way be partitioned to indicate the level of effort directed towards saithe.

Reliable estimates of recruitment are also lacking. For saithe, no useful method for estimating recruitment has yet been demonstrated.

Groundfish surveys have been commenced in some areas, but their potential usefulness for saithe stock assessments has yet to be determined.

Last year's Working Group noted inadequacies in the data base for saithe in Sub-area VI.

Data from 1979 onwards appear satisfactory but conflict with weight at age data estimates for previous years and suggest that the Scottish age/length keys applied to French data in earlier years may be inappropriate. A solution to this problem cannot be attempted until Scottish data are revised. It is hoped that this will be done before next year's meeting.

*) Preliminary

a) Data from national laboratories

b) In 1973 and 1974 estimates of industrial by-catches were included in the Norwegian catches reported to ICES. These estimates have later been revised and the sum of industrial by-catch and human consumption landings therefore deviate somewhat from the Bulletin Statistique figures.
