REPORT OF THE NORTH SEA ROUNDFISH WORKING GROUP

Copenhagen, 7 - 16 June 1983

This document is a report of a Working Group of the International Council for the Exploration of the Sea and does not necessarily represent the views of the Council. Therefore, it should not be quoted without consultation with the General Secretary.

REPORT OF THE NORTH SEA ROUND FISH WORKING GROUP

1. PARTICIPANTS

D W Armstrong	United Kingdom (Scotland)
E D Anderson	USA
N Daan	Netherlands
J P Hillis (part-time)	Ireland
B W Jones (Chairman)	United Kingdom (England)
J Lahn-Johannessen	Norway
F Lamp	Federal Republic of Germany
P Lewy	Denmark
C T Macer	United Kingdom (England)
O M Smedstad	Norway
T Smith	USA
A Souplet	France
G Wagner	Federal Republic of Germany

K Hoydal, ICES Statistician, also attended the meeting.

2. TERMS OF REFERENCE

At the 1982 Statutory Meeting of ICES it was decided (C.Res.1982/2:5:10) that the North Sea Roundfish Working Group should meet at ICES headquarters from 7-16 June 1983 to:

- (i) assess catch options for 1984 inside safe biological limits for cod, haddock and whiting in Sub-areas IV, VI and Divisions VII<sup>d,e</sup>,
- (ii) advise on possibilities other than by mesh regulations to improve the exploitation pattern on these stocks,
- (iii) review which data are available in the Working Group files for evaluating density dependence in the parameters of the models used in fish stock assessment,
- (iv) specify deficiencies in data required for assessments.

3. INTRODUCTION

At the 1981 meeting of the Working Group a new method was introduced, the Gamma method, for determining on an objective basis the levels of fishing mortality in the most recent year. The resultant values of  $F$  were then used to initiate the Virtual Population Analysis (VPA). There were subsequently some criticisms of the Gamma method mainly on the grounds that it did not allow for catchability varying with time. At the 1982 meeting the Working Group used a new method, the Rho method, which made allowance for changing catchability, and this method was considered by ACFM to be generally acceptable. Shortly before the 1983 North Sea Roundfish Working Group meeting there was a meeting of the Working Group on Methods of Fish Stock Assessment which, *inter alia*, examined the currently available methods which use catch and effort data to determine  $F$  values in the most recent year. As there was only one week between the meetings, members of the Roundfish Working Group did not have adequate time to assimilate and implement fully the recommendations of the Methods Working Group. Thus, the Roundfish Working Group had to adopt a pragmatic approach to the problem of tuning the VPAs by using the best of the methods for which computational software was available.

Three methods were attempted this year:

- (a) The Armstrong-Cook method as the method preferred by the Methods Working Group;
- (b) The Rho method for continuity and comparison with the 1982 assessments;
- (c) The Lewy method, which is a development of the Rho method, has the advantage that it calculates catchability at a fleet-disaggregated level.

These methods are described in greater detail in Section 5.

ACFM was critical of the Report of the 1982 meeting of the Working Group "because of the way the Working Group appeared to have discarded the IYFS data, although the difficulties in obtaining reliable estimates of recruiting year classes were appreciated". It was not the intention of the Working Group to discard the IYFS data, but during the 1982 meeting it became apparent that the difficulties in interpreting these data were greater than the Group was able to resolve in the available time. An International Gadoid Survey Working Group has been convened to meet in 1983 to examine the problems associated with the prediction of recruiting year class strength from survey data. Unfortunately, the Gadoid Group is not due to meet until July and consequently the Roundfish Working Group had to make its estimates of recruitment (see Section 6) in the absence of any advice, which might be given.

#### 4. REVISIONS TO DATABASE

##### Estimation of the Age Frequency Distributions of Haddock Discarded in Division VIa, 1965-77

Estimates of the numbers of haddock discarded at each age by Scottish vessels exist for the period 1978-82. These data were used to estimate the average number of haddock discarded per fish landed for ages 1 to 11 for each Scottish gear. Estimates of numbers discarded at each of these ages were then obtained for the period 1965-77 using the relationship

$$D(a,y,g) = L(a,y,g) \cdot X(a,g)$$

where  $a$  refers to age,  $y$  refers to year,  $g$  refers to gear,  $L$  refers to number landed,  $X$  is average number discarded per fish landed and  $D$  refers to discards.

In many cases no fish are landed at age 0, and it is therefore not possible to estimate the number discarded per fish landed. For this age group discards were estimated using the following relationship

$$\frac{D(0,y,g) / E(y,g)}{D(1,y+1,g) / E(y+1,g)} = K(g)$$

where  $E$  refers to fishing effort and  $K$  is the average ratio of discards per unit effort determined from data for the period 1978-82.

The values obtained by these methods are of course rather crude and it is hoped to improve on the estimation technique in the near future.

Mean weight at age for discards for the period 1965-77 was assumed to be equal to the mean value over all gears for the period 1978-82.

This was the only major revision to the database other than updating for the last two years. Updated total weights and total numbers for North Sea cod, haddock and whiting stocks can be found in Tables 4.1 - 4.3.

##### 5. DETERMINATION OF FISHING MORTALITY RATES IN THE LAST DATA YEAR

As mentioned in Section 3, the Working Group attempted to use three methods for determining  $F$  in the last data year:

- (a) The Rho method
- (b) The Lewy method (see Appendix)
- (c) The Armstrong-Cook method.

The program for the Rho method was available on the ICES computer, for the Lewy method on the Charlottenlund computer, and for the Armstrong-Cook method on the Aberdeen computer.

Individual fleet catch and effort data were available as indicated in the text table below, which also shows which fleet data were excluded from the final analysis.

+ indicates data available

X indicates fleets excluded from final analysis

Fleet	North Sea			West of Scotland		
	Cod	Haddock	Whiting	Cod	Haddock	Whiting
Scottish Trawl	+ X	+	+	+	+	+
Seine	+	+	+	+	+	+
Light Trawl	+	+	+	+	+	+
<u>Nephrops</u> Trawl	+ X	+ X	+ X	+ X	+ X	+ X
English Trawl	+	+ X	+ X	+ X	+ X	
Seine	+ X	+ X	+ X			
Netherlands Beam Trawl	+					

An initial decision was made to exclude the Scottish Nephrops trawl fleet data from all stocks because it was felt that these data are inappropriate for this purpose. English trawl and English seine data had to be excluded from the haddock and whiting analyses as there were no fleet discard data available.

Preliminary runs were made with both the Rho and the Lewy methods for the North Sea stocks and with the Rho method for West of Scotland stocks.

In general, the results for the methods were in good agreement. The Lewy method has the advantage that  $q$  values for each age in each year are calculated for each fleet separately. Plots were therefore made of  $q$  against year for each age/fleet combination. On the basis of these plots it was decided to exclude some additional fleet data before proceeding to the final analysis. For both haddock stocks both methods calculated  $F$  values for a number of age groups which were unrealistically high. The data for the North Sea haddock stock were transmitted to Aberdeen for use in the Armstrong-Cook program. The results from this method also gave unacceptable values for a number of age groups and none of these methods could be used this year for haddock. Logistical problems did not permit the Armstrong-Cook analysis to be extended to other stocks.

Although the results from the Rho and Lewy methods were generally in good agreement (see below) a decision had to be made as to which sets of F values were to be used in the assessments. The Working Group considered that the Lewy method was in principle preferable to the Rho method because it enabled the q values to be calculated on disaggregated fleet data. In addition, the program for the Lewy method incorporated a calculation of the coefficient of variation for the estimated F values. However, because of the convenience of access to the Rho method on the ICES computer, because the Rho method used the ICES VPA program, and in order to allow some comparison with the previous year's assessment, the Working Group decided to use the output from the Rho method. Input data, Gamma values, Rho values and regression analyses are given in Tables 5.1 - 5.12, and plots of the Rho values against time are given in Figures 5.1 - 5.6.

The text table below give the F values in 1982 for North Sea cod and whiting estimated by the two methods and also shows the 95% confidence limits associated with these estimates as calculated by the Lewy method. It should be noted that this confidence interval represents a minimum figure, as it relates only to the estimate of F from the regression line and does not include any error associated with the catch numbers and effort data.

North Sea Cod

Age	1	2	3	4	5	6	7	8
Rho F	.20	1.22	.96	.65	.67	.60	.77	.75
Lewy F	.21	1.46	1.04	.65	.75	.61	.76	.59
Lewy 95% Confidence Interval $\pm$	.06	.20	.14	.09	.09	.08	.11	.10

North Sea Whiting

Rho F	.78	1.14	.98	1.00	1.22	2.01	1.70	1.50
Lewy F	.76	.68	1.14	1.11	1.19	2.03	1.29	1.15
Lewy 95% Confidence Interval $\pm$	1.38	.22	.14	.18	.30	.72	.43	

6. ESTIMATION OF RECRUITMENT

Preliminary indices of abundance for the North Sea stocks for the 1982 and 1981 year classes were available from the 1983 IYFS. Indices were calculated as:

- (a) IYFS standard survey arithmetic mean index,
- (b) Burd-Parnell arithmetic mean index based on rectangles fished in all years;
- (c) Burd-Parnell geometric mean index based on rectangles fished in all years.

These indices are tabulated together with VPA year class strength estimates in Tables 6.1-6.3.

Plots were made of the various indices against VPA year class strength estimates, and for North Sea/West of Scotland relationship for VPA year class strength estimates. These plots for the IYFS standard arithmetic mean indices are reproduced in Figures 6.1-6.6 and Tables 6.4-6.6 and give the calculated coefficients for straight line geometric mean regressions.

The North Sea Roundfish Working Group did not wish to anticipate discussions expected to take place in the International Gadoid Survey Working Group (IGSWG). However, the Working Group suggests that the following points relating to the interpretation of IYFS data might be considered by the IGSWG:

- (1) What is the best computational method for deriving a survey index and, in particular, should the index be based on arithmetic or geometric average?
- (2) For estimation of absolute year class strength:
  - (2a) Is a straight line relationship appropriate?
  - (2b) If a line is fitted should a predictive or a GM regression be used?
  - (2c) Should a fitted line be forced through the origin?
  - (2d) Are there other means than the available linear regression techniques to reduce the coefficient of variation of the estimates?
- (3) Is the variance of the data sufficiently small for a useful prediction to be obtained?

The indications from the 1983 IYFS are that the 1982 year classes for all three species in the North Sea are of relatively low abundance.

Interpretation of the recruitment data is discussed for each stock in the appropriate section.

#### 7. NORTH SEA COD

##### 7.1 Catch Trends (Table 7.1 and Figure 7.1.A)

Provisional nominal landings in 1982 were 251 361 tonnes, compared to 290 296 tonnes in 1981. Unreported landings of 20 303 tonnes in 1981 and 4 573 tonnes in 1982 were also included in the Working Group estimates of landings. The TACs agreed between EEC and Norway for 1981 and 1982 (220 000 tonnes and 235 000 tonnes respectively) were thus exceeded by 90 649 tonnes and 20 182 tonnes in these two years.

##### 7.2 Age Composition (Table 7.2)

There were no revisions to the data base other than updating of the 1981 data and addition of 1982 data. As shown in the text table on p.6, only a very small proportion of the landings was not covered by sampling. As in previous years, discards and industrial fishery by-catches were not included in the VPA input data, since they are not considered to be reliably estimated.

NORTH SEA COD

Year	Category	Nations supplying age composition data	Weight represented by age compositions	Total weight caught	Percentage represented by age compositions
1981	Industrial by-catch	-	-	Not known	-
	Human consumption landings	Belgium, Denmark, England, Federal Republic of Germany, Netherlands, Scotland, France	303 467	310 599	98
	Discards	Netherlands, Scotland	10 919	Not known	-
1982	Industrial by-catch	Norway	368	Not known	-
	Human consumption landings	Belgium, Denmark, England, Federal Republic of Germany, Netherlands, Scotland, France	248 397	255 934	97
	Discards	Scotland	4 212	Not known	-

7.5 Recruitment (Table 7.5 and Figure 7.1.B)

The numbers of fish of the 1981 and 1982 year classes were estimated from IYFS-VPA plots.

1981 year class

This was estimated at 180 million fish at age 2 from the 1983 IYFS, using the correlation with VPA, which is highly significant. The catch at age 1 in 1982 implies an F value of 0.27 (the highest recorded value for this age group) and a stock number at age 1 of 290 millions. This value is supported by the English groundfish survey estimate of 260 millions at age 1. Last year there were uncertainties about the size of this year class as estimated by the IYFS at age 1. The Working Group used a value of 210 millions and ACFM finally adopted a value of 138 millions. The Rho estimate of F at age 1 in 1982 is 0.20 which implies a stock size of 388 millions. However, the Rho plot for this age group has a high variance probably due to the effects of discarding. The IYFS estimate is, therefore, preferred.

1982 year class

The IYFS in 1983 indicates a very low abundance for this year class. Inspection of various IYFS indices plotted against VPA showed that all gave a similar value for year class strength, since the scatter of points is reduced near the origin. The 1982 year class is indicated to be similar in size to the poor year classes of 1971, 1973, 1975 and 1980. The mean of these year classes is 110 millions and this value was adopted as the estimated size of the 1982 year class at age 1.

1983 year class

This was assumed as 202 millions at age 1, the average recruitment for the years 1963-79.

7.4 Weight at Age (Table 7.3)

Stock mean weights were assumed to be the same as catch mean weights. For predictions of catch in 1983 and 1984, mean weights were calculated as arithmetic means for the period 1977-82.

7.5 Fishing Mortalities in 1982 (Table 7.4)

F at age 1

Two estimates were available for this age group: that from the Rho method which gave 0.20 and that implied by the IYFS recruitment estimate which indicates an F of 0.27. The latter value is the highest yet seen in the VPA for this age group but is the preferred value, for the reasons described in Section 5.

F at other ages

These were estimated using the Rho method as described in Section 5. Catch and effort data were available for 6 fleets and these were examined separately using the Lewy method. This showed that in 2 fleets the variance about the regression line was rather higher than in the other 4 fleets. Exclusion of these 2 fleets in the Rho method gave slightly higher values for the correlation coefficient for older age groups and therefore the F values estimated are based on 4 fleet data sets. The F values obtained from using the data from all 6 fleets are in fact similar to the 4 fleet data.

The estimate at age 2 is higher than those previously estimated for this age by VPA, but the other values are similar to recent average levels.

The F values on the older age groups are lower than those indicated by the Rho method in last year's assessment. Although both sets of F values were estimated using the Rho method, this year's catch and effort data were updated by including Dutch data and by excluding fleet data showing relatively high variances. In addition, there were some revisions to English catch/effort data.

7.6 VPA Results (Tables 7.4 and 7.5, Figures 7.1.A-B)

Mean F on ages 3-8 increased between 1963 and 1972 but has remained relatively stable in subsequent years. Recruitment has fluctuated between 78 and 444 millions at age 1. Spawning stock biomass declined steadily from 1968 to 1978 but this trend has subsequently reversed.

7.7 Equilibrium Yield for Average Recruitment (Figure 7.1.C)

This was calculated using mean weights and mean Fs averaged over the period 1977-82. Yield was calculated for an average recruitment of 202 millions at age 1 (1963-79). The maximum yield is estimated at 315 000 tonnes at an F of 0.18 compared to recent average F (1977-82) of 0.74.

7.8 Catch Predictions

Input data are given in Table 7.6. The mean weights and exploitation pattern are the average for the period 1977-82. Results are given in Tables 7.7 and 7.8 and graphed in Figure 7.1.D.

1983

Two assumptions were considered:

$$\text{Assumption 1: } F_{83} = F_{82}$$

In this case a catch in 1983 of 223 000 tonnes at a mean F of 0.73 is produced. Last year's prediction was 200 000 tonnes at a mean F of 1.01.

$$\text{Assumption 2: Catch}_{83} = \text{TAC} = 240 000 \text{ tonnes}$$

Following this assumption F will increase by 12% to 0.82.

1984

Catches and spawning biomasses were calculated for a range of Fs for both options in 1983. At constant F, catches in 1984 are predicted at 183 000 tonnes under Assumption 1, and 169 000 tonnes under Assumption 2 ( $F_{84} = F_{82}$ ). The decreased catches in 1984 are primarily the result of the low abundance of the 1982 year class.

8. COD IN DIVISION VIa

8.1 Catch Trends (Table 8.1, Figure 8.1.A)

Provisional nominal landings in 1982 were 21 544 tonnes compared to 23 950 tonnes in 1981. Despite the decrease in landings in 1982, the quantity was nevertheless high compared to recent levels. The TAC recommended by ACFM for 1982 was 17 000 tonnes.

8.2 Age Composition (Table 8.2)

Details of data supplied for the past 2 years are given in the text table below. There were no changes in the VPA input data for years prior to 1981. The data base does not include estimates of discards.

<u>Year</u>	<u>Nations supplying age composition data</u>	<u>Weight represented by age composition</u>	<u>Total weight caught</u>	<u>% represented by age composition</u>
1981	England, Ireland, Scotland	16 222	23 921	68
1982	England, Ireland, France, Scotland	21 485	21 740	99

8.3 Recruitment (Table 8.5, Figure 8.1.B)

1981 year class

The VPA correlation with the North Sea is non-significant (1 year old) or only just significant (2 years old) and so it was decided to use an average value of F to determine the strength of this year class. The mean for the period 1977-79 (0.10) was selected, and this results in an estimate of 21.3 millions at age 1. This is the largest year class yet seen in the VPA but this estimate is supported by Scottish cpue data (Table 5.3). Although the Rho method is potentially less reliable for this age group, the estimate of 20.7 millions, which it indicates, is very close to the adopted value of 21.3 millions, as calculated from mean F.

1982 and 1983 year classes

There is a clear upward trend in recruitment since 1965. However, the Group decided that it would be inadvisable to extrapolate this trend, since to do so would estimate the 1982 and 1983 year classes as being of high abundance and hence we would obtain a very optimistic forecast. For this reason it was assumed that the abundance of the 1982 and 1983 year classes is 7.7 millions at age 1, the mean for the period 1967-79.

8.4 Weight at Age (Table 8.3)

The mean weight data for the period 1967-78 are a nominal constant series, set at the 1978 level. For this period, biomass estimates should be treated with caution.

8.5 Fishing Mortalities in 1982

F at age 1

This was assumed to be the same as the average for the years 1977-79 (0.10). The Rho method gives an almost identical value.

F at other ages

These were estimated using the Rho method. Data from 4 fleets were examined initially. In one of them (English trawl), fishing effort has declined drastically in the last few years and this resulted in some anomalous gamma values which biased the corresponding Rho estimate. This fleet was therefore excluded from the Rho analyses. Except at age 5, the estimated Fs are in good agreement with recent values.

8.6 VPA Results (Tables 8.4-8.5, Figure 8.1.B)

Mean F has shown an increasing trend over the whole period (1967-82). Recruitment has also tended to increase and fluctuations have also become more marked in recent years. After remaining at a constant level during the period 1971-80, spawning stock biomass has increased over the past two years.

8.7 Yield at Average Recruitment (Figure 8.1.C)

This was calculated using mean weights and mean fishing mortalities for the period 1977-82. A mean recruitment of 7.7 millions (1967-79) was assumed. The maximum yield is calculated as 15 500 tonnes at an F of 0.31. Recent average F has been 0.83.

8.8 Catch Predictions

The input data are given in Table 8.6. The mean weights and exploitation pattern are averages for the period 1977-82.

1983

In the absence of an agreed TAC for 1983, only a single option ( $F_{83} = F_{82}$ ) was assumed. The predicted catch is 22 600 tonnes at a mean F value of 0.84. In last year's assessment a catch of 25 700 tonnes was predicted at an F of 0.71.

1984

Table 8.7 and Figure 8.1.D give the predicted catches and spawning biomass for a range of Fs. If F remains constant in 1984, a catch of 23 200 tonnes is predicted.

9. COD IN DIVISION VIb

No age compositions are available for this stock, but nominal landings are quite small (Table 9.1). If a TAC is set for the whole of Sub-area VI, an appropriate allowance will need to be made for Division VIb.

10. COD IN SUB-AREA VII

10.1 Cod in Divisions VII<sub>d</sub> and e (Table 10.1)

As in previous years the only data available were from England, but based on limited sampling. Since English landings form only a small proportion of the total, no analytical assessment was attempted.

10.2 Cod in Divisions VII<sub>b,c</sub> and VII<sub>g-k</sub> (Table 10.2)

No age compositions are available for these areas.

11. NORTH SEA HADDOCK

11.1 Catch Trends

Total international landings and total international catches are given in Table 11.1 and shown in Figure 11.1.A for the period 1960-82.

The TAC for 1982 was 180 000 tonnes and provisional nominal landings for that year are 181 049 tonnes. The Working Group's estimate of total landings for 1982 is 186 463 tonnes. Discards for 1982 were estimated at 41 308 tonnes.

11.2 Age Composition

Details of the data supplied to the Working Group by various nations for 1981 (final) and for 1982 (provisional) are summarized in the text table below:

Year	Category	Nations supplying age composition data	Weight represented by age composition	Total weight caught	% represented by age composition
1981	Industr.	Denmark, Norway	16 216	17 615	92
	Human consump.	Belgium, Denmark, England, France, Netherlands, Scotland	122 961	130 009	95
	Discards	Scotland	38 527	60 290	64
1982	Industr.	Denmark, Norway	19 969	20 980	95

11.3 Weight at Age

Mean weight at age data for the total catch (used as stock weights) are given in Table 11.3.

11.4 Recruitment (Table 11.5, Figure 11.1.B)

1982 year class

Recruitment indices for the 1982 year class at age 1 in 1983 were available from the IYFS. These indices indicated that the 1982 year class is of very low abundance. The scatter diagram of IYFS index versus VPA number indicates a curvilinear relationship whereas the basic assumption made in the past was that the relationship should be rectilinear. Pending the deliberations of the forthcoming Young Gadoid Survey Working Group it was decided to estimate the absolute abundance of this year class by inspection of the scatter diagram of IYFS index versus VPA rather than by regression methods. This resulted in an estimate of 760 million fish at age 1 in 1983.

1981 year class

For the first time in this Working Group an index of abundance for 2-year old haddock was also available from the IYFS. This allowed estimation of the absolute abundance of the 1981 year class in 1983 from Figure 6.4.A. The abundance estimated by use of regression methods was 760 million fish at age 2. Given the catch of this year class at age 1 in 1982, this implies that the abundance of the 1981 year class at age 1 was about 1250 million fish. Inspection of the IYFS index for age 1 fish gives a very similar result.

Recruitment at age 0 in 1983, 1984 and 1985 was assumed to be 2695.318 millions, this value being the average for the period 1961-79 excluding the 1967 year class.

11.5 Fishing Mortalities in 1982 for Age Groups 0 to 11+

As noted in Section 5, none of the methods available for the estimation of these values produced acceptable results. It was therefore decided to use mean values of fishing mortality rates for the period 1978 through 1980.

Fishing mortalities at age 0 and 1 in 1982 were evaluated to produce the abundance levels estimated from the IYFS.

11.6 VPA Results

Estimated fishing mortalities for the period 1960-82 are shown in Table 11.4 and the corresponding stock number and stock biomasses are shown in Table 11.5.

Historical spawning stock biomasses are shown in Figure 11.1.B.

Current spawning stock size is higher than that for the period 1978-79 when the stock size was at almost the lowest recorded level.

11.7 Equilibrium Yield for Average Recruitment

Equilibrium yield and spawning stock size are shown in Figure 11.1.C.

11.8 Catch Predictions

Input data for catch predictions are shown in Table 11.6.

Only one set of options was calculated, since assuming  $F_{83} = F_{82}$  produces a predicted catch (human consumption landings + industrial by-catch) of 182 000 tonnes. This is almost identical to the agreed TAC for 1983 of 181 000 tonnes.

Predicted catches for 1984 are presented in Table 11.7 and are also shown graphically in Figure 11.1.D.

12. HADDOCK IN DIVISION VIa

12.1 Catch Trends (Table 12.1)

Nominal landings in 1982 were 28 883 tonnes and the Working Group-estimated total (29 228 tonnes) did not differ appreciably from this value.

The weight of haddock discarded in the period 1965 to 1977 was estimated by the methods explained in Section 4. Scottish discard data were raised to total international level for the period 1978-82.

Figure 12.1.A shows estimated weight landed and discarded since 1965.

12.2 Age Composition (Table 12.2)

Details of the data supplied to the Working Group by various nations for 1981 (final) and for 1982 (provisional) are summarized in the text table below.

Year	Category	Nations supplying age composition data	Weight represented by age compositions	Total weight caught	% represented by age compositions
1981	Human consump.	England, Ireland, France, Scotland	14 775	18 218	81
	Discards	Scotland	9 980	15 060	66
1982	Human consump.	England, Ireland, France, Scotland	29 112	29 228	100
	Discards	Scotland	6 554	9 910	66

12.3 Weight at Age

Mean weight at age data for the total catch (used as stock weights) are given in Table 12.3. The values shown now include data on discards and are therefore different from corresponding values presented in previous reports.

12.4 Recruitment (Table 12.5)

The abundance of the 1982 year class in 1983 was estimated by inspection of the scatter diagram of VPA in Division VIIa versus VPA in Sub-area IV (Figure 12.1.B) as 48 millions at age 1. A similar procedure was adopted to estimate the abundance of the 1981 year class in 1982 as 102 millions at age 1.

Average recruitment of 173.286 millions at age 0 (mean value for 1965-79 excluding the 1967 year class) is assumed for the years 1983, 1984 and 1985.

12.5 Fishing Mortalities in 1982 for Age Groups 0 to 11+

As noted in Section 5 none of the methods available for the estimation of these values produced acceptable results. It was therefore decided to use mean values of fishing mortality rates for the period 1978 through 1980.

Fishing mortalities at ages 0 and 1 were chosen to produce the stock abundances at those ages indicated in the preceding section.

12.6 Fishing Mortalities at Age 11 for 1965 to 1981

These values were adjusted by inspection of trial VPAs to be more or less in accordance with F at ages 7-9.

12.7 VPA Results

Estimated fishing mortalities for the period 1965-82 are shown in Table 12.4 and the corresponding stock numbers and stock biomasses are shown in Table 12.5.

Historical spawning stock biomasses are shown in Figure 12.1.B.

Current spawning stock size is about three times as great as that in 1979 when the stock size was at the lowest recorded level.

12.8 Equilibrium Yield for Average Recruitment

Equilibrium yield and spawning stock size are shown in Figure 12.1.C for an average recruitment at age 0 of 173.286 million.

12.9 Catch Predictions

Input data for catch predictions are shown in Table 12.6.

Since no TAC has been agreed for Division VIa, only one set of catch predictions, assuming  $F_{83} = F_{82}$ , was made. The landings predicted for 1983 on this basis are 38 000 tonnes, which is considerably higher than the catch of 29 200 tonnes in 1982.

Predicted catches for 1984 are presented in Table 12.7 and are also shown graphically in Figure 12.1.D.

It should be noted that the predictions presented in this report are not comparable to those previously presented since discards are now included in the data base. In particular, the inclusion of the discards has considerably increased our estimate of the abundance of the 1979 year class, which results especially from the estimate of the numbers of fish of this year class discarded at age 2 in 1981. It is estimated that the landings from this year class alone in 1983 will be about 25 000 tonnes.

13. HADDOCK IN DIVISION VIb

13.1 Catch Trends (Table 13.1)

The English fishery on Rockall Bank continued in 1982 taking a catch of 7 700 tonnes compared with 9 000 tonnes in 1981. Landings by other countries were insignificant and amounted to only 68 tonnes in 1982.

13.2 Stock Assessment

Again in 1982 sampling of commercial landings was not possible because they were not landed in the United Kingdom. The English research vessel trawl survey made in 1981 was repeated in 1982, and some additional stations were worked. Also in 1982 a trawl survey was undertaken by the Scottish research ship "Scotia".

For the English surveys, the data for the two years can be compared for the 45 stations which were common to both surveys. The catch age compositions and weights caught were as follows:

Age	Number per 45 hauls	
	1981	1982
0	353 962	
1	95 650	96 767
2	323	69 808
3	164	1 844
4	5 496	1 555
5	25 692	6 577
6	0	22 804
7	417	0
8	551	1 999
9	59	1 148
10+	3	16
Total N	482 317	202 520
Total weight	36 148	48 490
Total N ages 1-10+	128 355	202 520
Total weight ages 1-10+	30 596	48 490

In the 1982 survey, which was made in July, no 0-group fish of the 1982 year class were caught, whereas in 1981 when the survey was conducted in August large numbers of 0-group fish were caught. It was not clear whether the 1982 year class is a failure or whether the survey was too early for the 0-group fish to be available on the bottom. For the remaining year classes the results of the two surveys are consistent in showing the 1976, 1977, 1980 and 1981 year classes to be abundant. Other year classes are poor or virtual failures and contribute very little to the catch. Catch rates (in weight) of fish at age 1 and older were 58% higher in 1982 than in 1981. This increase is less than the doubling that was predicted on the basis of the 1981 survey alone.

Estimates of mortality rates between years for the various year classes are highly variable. For the poor year classes this is probably due to sampling error. For the abundant year classes the indication is that mortality rates are low, but it is possible that survey results may be affected by changes in seasonal availability.

The general indications are that current catch levels could be maintained in 1983, but the prospects for 1984 are less certain because of the absence of information on the abundance of the 1982 year class.

Information from the 1982 fishery indicated that catch rates were high and that large individual hauls were being taken. In these circumstances selectivity of trawl cod ends tends to be reduced. In the 1982 situation with high abundance of 1- and 2-year old fish in the selection range, it is thought that a high proportion of fish in the catches would have been below legal minimum landing size and to conform with conservation regulations would have required a high rate of discarding.

14. HADDOCK IN SUB-AREA VII

Nominal catches of haddock in Divisions VIId,e and in VIIb,c,g-k are given in Tables 14.1 and 14.2. No other data were available, and no assessment could be attempted.

15. NORTH SEA WHITING

15.1 Catch Trends (Table 15.1, Figure 15.1.A)

The provisional nominal landings for 1982 amount to 102 000 tonnes, which is close to the catch reported for 1981 and below the TAC agreed for 1982 of 170 000 tonnes. The Working Group estimates of total catches, however, differed considerably between 1981 (192 000 tonnes) and 1982 (134 000 tonnes).

15.2 Age Composition (Table 15.2)

The age composition data for 1981 were updated and provisional estimates for 1982 were prepared.

Details of the data supplied to the Working Group by various nations for 1981 and 1982 are summarized in the following text table:

Year	Category	Nations supplying age composition data	Weight represented by age compositions	Total weight caught	% represented by age compositions
1981	Industrial by-catch	Denmark, Norway	63 132	66 595	95
	Human consump.	England, France, Netherlands and Scotland	76 746	80 018	96
	Discards	Netherlands and Scotland	17 117	45 560	38
1982	Industrial by-catch	Denmark, Norway	31 970	32 990	97
	Human consump.	Belgium, England, France, Netherlands, Scotland	72 118	72 381	100
	Discards	Scotland	9 945	29 004	34

#### 15.3 Recruitment

The abundance of the 1982 year class at 1 year old and the 1981 year class at 2 years old were both estimated at  $500 \times 10^6$  million fish at age 1 and 2, respectively on the basis of the preliminary indices of these year classes in the 1983 IYFS. These estimates were obtained by inspection of the appropriate VPA/IYFS scatter diagram (Figures 6.5 and 6.6).

The F values implied by these recruitment figures on 0- and 1-year old whiting in 1982 were on the low side, but they were not considered to be unrealistically low.

The recruitment at age 0 entering the fishery in 1983 and subsequently was assumed to correspond to the average recruitment at age 0 of  $2 700 \times 10^6$  fish during the time period 1961-80.

#### 15.4 Weight at Age

Mean weight at age data for total catches (used as stock weights) are given in Table 15.3.

#### 15.5 Fishing Mortalities in 1982 for Age Groups 2-9

Fishing mortalities in 1982 for these age groups were obtained by the Rho method (see Section 5).

#### 15.6 VPA Results

Estimates of F calculated by VPA are given in Table 15.4. The average F values over the age groups 2-6, although variable from one year to another, were considered to justify a constant terminal F value on the oldest age groups in the catch of 1.0. The average value obtained in 1982 was slightly above the values obtained for the preceding period.

Estimates of stock numbers and spawning stock biomass are given in Table 15.5. Due to a steady decline in recruitment from year class 1978 onwards, the spawning stock biomass shows a pronounced downward trend since 1980, although in 1982 (210 000 tonnes) it was still higher than the lowest value on record (Table 15.5, Figure 15.1.B).

15.7 Equilibrium Yields for Average Recruitment

Long-term equilibrium yields in terms of total landings and human consumption landings are presented in Figure 15.1.C. Input data were those used for catch predictions (Table 15.6). In calculating these yields  $F$  for the industrial fisheries has been kept constant. Also the proportion discarded, the average for the last 6 years, has been kept constant, irrespective of  $F$  resulting from the human consumption fishery.

The actual yield curve presented strongly depends on these assumptions and so do the biological reference points, which therefore have not been calculated. The  $F$  level in the human consumption landings is indicated.

15.8 Catch Prediction (Table 15.7 and Figure 15.3)

Input data for the catch predictions are given in Table 15.6. The following primary assumptions were made when carrying out the predictions:

- 1) The partial exploitation pattern in the human consumption fishery (landings and discards) in 1983 would be the same as the average partial human consumption exploitation pattern over the period 1977-82, the level being scaled to the average value of fishing mortality over the age groups 2-6 in 1982. The exploitation pattern and the level of fishing mortality in the industrial fishery were assumed to correspond to the average pattern and level in this fishery over the period 1977-82. The overall exploitation pattern was obtained by adding the two patterns in the human consumption and the industrial fishery.
- 2) Mean weight at age in the stock and in the various categories of catch would remain the same as the average for 1977-82.
- 3) Discarding rates at age would be the same as the average rates for 1977-82.

No catch prediction was made for the assumption that the catch in 1983 would equal the agreed TAC of 170 000 tonnes, because this would result in unrealistically high fishing mortalities. Therefore only the assumption with  $\bar{F}_{83}^{hc} = \bar{F}_{82}^{hc}$  was pursued, which gives landings in 1983 of 93 000 tonnes.

Attention is drawn to the development in the spawning stock biomass (SSB). The estimated SSB in 1984 is 127 000 tonnes, which represents the lowest value on record. This recent decrease is due to a sequence of bad year classes. Although in the prediction for 1985 the SSB is back at a much higher level, this calculated increase is entirely due to the assumption that the 1983 year class, which enters the SSB in 1985, is of average size. In view of the downward trend in recruitment in recent years and without any information on recruitment in 1983, the estimated SSB in 1985 cannot be relied upon.

16. WHITING IN DIVISION VIa

16.1 Catch Trends (Table 16.1 and Figure 16.1.A)

The revised reported landings of 18 477 tonnes taken in 1981 are well above the provisional figure of 11 800 tonnes reported in 1982.

However, the Working Group estimate of 12 664 tonnes was used in the assessment. The provisional landings in 1982 were 13 540 tonnes. There was no agreed TAC in effect. The estimated total catch including discards was 18 770 tonnes.

#### 16.2 Age Composition (Table 16.2)

The age composition data for 1981 were revised. Provisional age compositions for 1982 were compiled. In addition to data on the human consumption landings, discard data were provided by Scotland. However, since these are available for one year only, they have not been used in the assessment. Details of the data supplied to the Working Group are summarized in the text table below.

Year	Category	Nations supplying age composition data	Weight represented by age compositions	Total weight caught	% represented by age compositions
1981	Human consumption landings	France, Ireland, Scotland	12 491	12 664	98
1982	Human consumption landings	France, Ireland, Scotland	13 265	13 540	98
	Discards	Scotland	3 253	5 230	62

#### 16.3 Recruitment

With reference to Section 6, abundance figures of the 1982 year class at 1 year old and the abundance of the 1981 year class at 2 years old were estimated from the regression lines of VPA recruitment indices for Division VIa on the VPA recruitment indices for Sub-area IV for the two age groups, respectively. According to the lines connecting  $\bar{x}$ ,  $\bar{y}$  and the origin, the number of the 1982 year class at 1 year old was estimated at  $20 \times 10^6$  fish and the number of the 1981 year class at 2 years old were estimated at  $14 \times 10^6$  fish.

The F value implied by the recruitment figure for the 1981 year class of 0.18 in 1982 was not considered to be anomalous.

The number of recruits at age 1 entering the fishery in 1984 and subsequently was assumed to be  $88 \times 10^6$ , which is the average number of 1-group whiting during the period 1963-80.

#### 16.4 Weight at Age

Mean weight at age data for total catches (used as stock weights) are given in Table 16.3.

#### 16.5 Fishing Mortalities in 1982 for Age Groups 2-6

Fishing mortalities in 1982 for these age groups were obtained by the Rho method (see Section 5).

#### 16.6 VPA Results

Estimates of F from the VPA are given in Table 16.4. The average F values over the age groups 2-4 are consistently lower than the terminal

F values for the oldest age group during the whole time period. However, since discard data are not included in this assessment, the average fishing mortalities are underestimated and the terminal F values used generally appear to correspond with the estimated mortalities in 5- and 6-year old whiting.

The F level estimated in 1982 from the Rho method is somewhat higher than in the results from the VPA indicated for the preceding years.

Estimates of stock numbers and spawning stock biomasses are given in Table 16.5. Spawning stock biomass (ages 2+) has dropped in 1982, due to the poor 1980 year class reaching maturity (Figure 16.1.C).

#### 16.7 Equilibrium Yield for Average Recruitment

Yield was calculated using an exploitation pattern and mean weights at age equal to the averages 1977-82. The flat curve (Figure 16.1.C) has no clear maximum. The  $F_{0.1}$  is indicated in the figure, although it must be observed that due to lack of information on discards both the real exploitation pattern, and thus the yield curve, remain unknown.

#### 16.8 Catch Prediction

The input data for the catch predictions are given in Table 16.6.

The primary assumption about exploitation pattern and mean weight at age in 1982 and 1983 were the same as described for North Sea whiting, except that no consideration was given to discards, for which no adequate data are yet available. There has not been an agreed TAC for whiting in 1983 in Division VIIa and, therefore, only the assumption that  $\bar{F}_{83} = \bar{F}_{82}$  has been considered.

The results of the prediction runs are shown in Tables 16.7 and are also given in Figure 16.1.D.

The estimated spawning stock biomass (2+ whiting) in 1985 should be treated with care, because a major proportion of this biomass consists of the 1983 year class, which has been assumed to be of average size. Despite the recent series of bad year classes, the low spawning stock biomass of 8 000 tonnes estimated at the beginning of 1984 is therefore bound to increase in any prediction runs based on average recruitment of the 1983 year class.

The landings estimated for 1983 of 8 200 tonnes in the present assessment are considerably smaller than the value of 12 100 tonnes predicted in the 1982 Working Group report. This discrepancy is due to the fact that in the former assessment the recruitment of the 1982 year class at 1 year old was assumed to be of average size ( $87\ 046 \times 10^3$ ), whereas now it has been estimated as a poor year class ( $20\ 486 \times 10^3$ ).

### 17. WHITING IN SUB-AREA VII

#### 17.1 Whiting in Divisions VIId, e

Landing figures for 1981 have been revised from 8 271 tonnes to 10 804 tonnes, which brings the catch back to the level observed in the mid-1970s (Table 17.1). Provisional landings in 1982 are 8 640 tonnes.

The age composition of the total catch in 1981 has been revised. For 1982, age composition data have been submitted by England and France covering 99% of the provisional landings.

A VPA was made to give some indication about the level of exploitation. The input catch data are given in Tables 17.2-17.3. Both catch at age and weight at age data reveal an apparent discontinuity in 1981: the numbers landed of the older age groups are rather larger during the last

two years than during the earlier period, whereas the weights at age are consistently lower over the age range. The fishing mortalities are given in Table 17.4. In the absence of catch per unit of effort data the input values for the last data year were adjusted in an iterative procedure to correspond with the resultant averages over the period 1976-79. The terminal F values on the oldest age group were arbitrarily set at 1.0. The stock estimates (Table 17.5) show a sudden increase in abundance of older age groups in 1981. However, these results cannot be relied upon, because the discontinuity in the input data in 1980/81 is likely to indicate a major sampling problem in this fishery.

17.2 Whiting in Divisions VIIb,c and VIIg-k (Table 17.6)

Landings in 1980-82 fluctuated around 9 000 tonnes as they did in the earlier period of 1973-76.

18. POSSIBILITIES FOR IMPROVING THE EXPLOITATION PATTERNS OTHER THAN BY MESH REGULATION

For North Sea cod there have been suggestions that some fleets have been concentrating in areas where young fish predominate and are consequently taking a high proportion of young cod in their catches. One area that has been mentioned in this context is the Helgoland Bight. Figure 18.1 shows the main areas of distribution of 0-, 1- and 2-groups cod in the southern North Sea in each quarter of the year based on research vessel survey data for the period 1980-82. This shows that young cod are concentrated in the German Bight at certain times of the year.

No data were available at the Working Group meeting giving an area breakdown of quantities caught together with the associated age compositions. Consequently, it was not possible to estimate what proportions of young fish were taken in any particular area. Detailed data of this kind would be required for any quantitative assessment of cod. In addition, it would also be essential to have estimates on discards by area. Furthermore, any local conservation measures, which might be contemplated, would also have implications for fisheries for other species, which take place in the same area.

For haddock and whiting in the North Sea the two major factors influencing the exploitation pattern are the catches of undersized fish taken with current human consumption fishery mesh sizes and subsequently discarded and the by-catches in the industrial fisheries. The first of these problems is probably best resolved by mesh regulation. The second problem is more a question of policy and economics relating to the co-existence of industrial and human consumption fisheries.

19. DATA AND WORKING GROUP FILES FOR EVALUATING DENSITY DEPENDENCE IN THE PARAMETERS USED FOR STOCK ASSESSMENT

Data are available in the Working Group computer files which enable stock biomass to be calculated. These data include weight at age estimates, which could be used for density-dependent growth analyses. However, because sums of products corrections have been applied in many cases the interpretation of these data requires some care. Year class strength estimates are available from VPA for stock recruitment analyses. No detailed maturity ogive data are available to examine possible density-dependent maturity relationships.

In addition to the aggregated data in the Working Group files, more detailed national data are available at various institutes.

20. DEFICIENCIES IN THE DATA

Some countries were still unable to present properly prepared data at the beginning of the Working Group meeting, even though this year the Group did not meet until June. Work on assembling the basic age composition data was therefore delayed while telephone calls and telexes were sent to obtain national data.

Some uncertainties remain unresolved for Irish data for Division VIIa.

The Working Group used IYFS indices to help determine the abundance of recruiting year classes. The indices prepared from the 1983 IYFS were incomplete, because some countries had not met deadlines for submitting survey data to the IYFS Coordinator.

For Item 2 of the terms of reference, data are required giving catches (landings and discards separately) together with associated age composition data split on an area basis. It would also be helpful to the Working Group, if the problems requiring analysis could be specified more explicitly with a definition of any areas which might be subject of any special concern.

Knife-edge age at maturity has been used for all stocks for spawning stock biomass estimates. It is hoped that at the next meeting, maturity ogives will be available for three years for the North Sea stocks from IYFS data.

Discard estimates have not yet been worked up for the Division VIIa whiting stock. Discard data for Division VIIa haddock were included in the assessment for the first time this year.

For West of Scotland cod mean weight data for the period 1967-77 need to be revised.

For Divisions VIId,e whiting there appear to be some sampling problems.

21. RECOMMENDATIONS AND SUGGESTIONS

It is recommended that the ICES VPA programme be enhanced to enable the partial F values to be calculated for each category of catch.

It is suggested that if alternative F indices to those used in this report are recommended either by ACFM or by the Working Group on Fish Stock Assessment, then consideration should be given to whether the proposed indices can be used for expressing the average partial F in the different categories separately.

The Working Group recommends that the suitability of industrial by-catch data for recruitment predictions is examined.

---

Table 4.1 North Sea. COD. Numbers ('000) and weight (tonnes) in each category.

Year	Human consumption		Discards		Total	
	Number	Weight	Number	Weight	Number	Weight

\* Not significant

1) Based on the mean value of the poor year classes 1971, 1973, 1975 and 1980

2) Based on the regression of VPA-IYFS standard: see also Section 7.4

3) Because the correlation coefficient is not significant average recruitment has been assumed

4) See Section 8.3

x) Provisional figures.

a) Figures from Norway do not include whiting caught in Rec.2 fisheries. For 1973 and 1974 Rec.2 fisheries were officially reported, but have been deducted from the figures given here to make a consistent time series.

b) 1973-74 include Div. IIIa, 1978 included in Div. IIIa.

c) Include discards.

## APPENDIX A

THE LEWY-METHOD

The basic idea is to evaluate the development of the catchability for each fleet and age group separately. This is an advantage compared to the Gamma and Rho methods. Both these methods consider the catchability of the total fleet. Hence it is not possible to distinguish between technological developments in each fleet and changes in the total fleet composition. As, for example, the structure of the Scottish fleet has changed drastically since 1966 this improvement might be important. Estimation of catchability on fleet disaggregated data should result in better estimates of  $F$  than are obtained using the Rho model.

## The Model

It is assumed that

where  $F$  denotes fishing mortality rate,  $q$  catchability coefficient,  $E$  the effort,  $f$  the fleet,  $a$  the age, and  $y$  the year.

Contrary to the Gamma method  $q$  is assumed to be independent of the number of fish in the sea.

According to (1)  $q$  can be estimated as follows

where  $C$  is the catch, and  $\bar{N}$  the average number of fish in the sea estimated from the VPA.

## NOTATION

Age	$a = 1, 2, \dots, A$ ( $A_1, A_2$ ) is the age range, where reasonable estimates of $q$ are obtainable)
Fleet	$f = 1, 2, \dots, F_1$
Year	$y = 1, 2, \dots, Y$ $Y_1$ = the last year for which estimates of $q$ are used in regression analysis
$q(f, a, y)$	and $\hat{q}(f, a, y)$ denote catchability coefficients
$F(f, a, y)$	denotes fishing mortality rate for fleet $f$
$C(f, a, y)$	denotes catch in numbers for fleet $f$
$E(f, y)$	denotes fishing effort
$F(a, y)$	and $F_{NEW}(a, n)$ denote fishing mortality rates for total mortality rates for total international values
$C(a, y)$	denotes catch in number for total international values
$N(a, y)$	denotes the average number of fish in the sea

### Computational Procedure

1. Input arbitrary values of  $F(a,Y)$  and  $F(A,y)$ ,  
 $a = 1,2,\dots,A$ , and  $y = 1,2,\dots,Y$  in the VPA
  2. Perform VPA
  3. Estimate

$$q(f, a, y) = \frac{C(f, a, y)}{E(f, Y) \cdot N(a, y)} = \frac{C(f, a, y) \cdot F(a, y)}{E(f, y) \cdot C(a, y)} \quad A1 \leq a \leq A2 \dots \dots \dots \quad (7)$$

4. Perform linear regression for each fleet and age group:

$$\hat{q}(f, a, y) = \alpha(f, a) + \beta(f, a)(y - \bar{y}) \quad y = 1, 2, \dots, Y$$

5. Estimate  $\hat{q}(f, a, Y)$

6. Estimate  $\hat{F}(f, a, Y) = \hat{q}(f, a, Y) \cdot E(f, y)$

7. Reestimate total international F in year Y

$$FNEW(a, Y) = \sum_f \hat{F}(f, a, Y) \frac{C(a, Y)}{\sum_f C(f, a, Y)} \quad \text{Al } a \leq A2$$

8. If  $\sum_{i=1}^{A2} (\text{FNEW}(a, Y) - F(a, Y))^2 < 10^{-5}$  then stop else go to 2. .... (4)

### The Variance of Terminal F

From the computational procedure it is possible to calculate the variance and therefore the confidence limits of the estimated terminal F.

Let the age group be given.

For each age group we have that

$$F_{NEW}(y) = \sum_f \hat{F}(f, y) \cdot C(y) / \sum_f C(f, y) \quad \dots \dots \dots \quad (6)$$

Assume that the effort,  $E$ , and the catches,  $C$ , are determined without any sampling or other errors, such that their variances are assumed to be zero. Assume further that the catches of one fleet is stochastically independent on the other fleets. As a consequence  $\text{COV}(\hat{F}(f,y), \hat{F}(g,y)) = 0$ .

The variances of (5) and (6) are now

$$\text{VAR}[\bar{F}(f,y)] = (\mathbb{E}(f,y))^2 \quad \text{VAR}[\bar{q}(f,y)] \dots \dots \dots \quad (7)$$

$$\text{VAR} \left[ \bar{F}_{\text{NEW}}(y) \right] = \sum_f \text{VAR} \left[ \hat{F}(f, y) \right] + \left( C(y) / \sum_f C(f, y) \right)^2 \dots \quad (8)$$

The variance of the estimated catchability in the last year,  $\hat{q}(f,y)$ , is estimated by

where  $\sigma^2$  is the variance about the regression line.

The variance (9) should be considered as a minimum value as the variances of the catches and the effort figures of course are bigger than zero. The variance of terminal F estimated in (6) is therefore a lower limit too.
