## Contents

Executive Summary ..... 1
1 Introduction ..... 1
1.1 Main Tasks ..... 1
1.2 Participants ..... 3
1.3 Management framework for salmon in the North Atlantic ..... 3
1.4 Management objectives ..... 4
1.5 Reference points and application of precaution .....  4
2 ATLANTIC SALMON IN THE NORTH ATLANTIC AREA ..... 6
2.1 Catches of North Atlantic Salmon ..... 6
2.1.1 Nominal catches of salmon ..... 6
2.1.2 Catch and release ..... 7
2.1.3 Unreported catches ..... 7
2.2 Farming and Sea Ranching of Atlantic Salmon ..... 8
2.2.1 Production of farmed Atlantic salmon ..... 8
2.2.2 Harvest of ranched Atlantic salmon ..... 8
2.3 NASCO has asked ICES to report on significant, new or emerging threats to, or opportunities for, salmon conservation and management ..... 8
2.3.1 Recovery potential of Bay of Fundy and Southern Upland salmon populations ..... 8
2.3.2 Monitoring interactions between aquaculture and wild fisheries in Norway ..... 10
2.3.3 Cessation of mixed stock fisheries in Irish coastal waters from 2007 ..... 11
2.3.4 Development of predictive models for returning salmon in Norway ..... 12
2.3.5 Human activities impacting on aquatic diversity ..... 12
2.3.6 Timing and nature of density dependence in Atlantic Province salmon populations ..... 13
2.3.7 Autumn downstream migration of juvenile Atlantic salmon in the UK - possible implications for the assessment and management of stocks ..... 14
2.4 NASCO has asked ICES to provide a framework of indicators which would be used to identify any significant change in the previously provided multi-annual management advice for each Commission area ..... 15
2.4.1 Study Group on Establishing a Framework of Indicators of Salmon Stock Abundance ..... 15
2.4.2 Update of the Framework of Indicators for the 2007 to 2009 multi-year catch advice at West Greenland ..... 16
2.4.3 Application of the framework indicator spreadsheet for signalling whether a significant change in management advice may occur for the fisheries in 2008 and 2009 ..... 17
2.5 NASCO has asked ICES to examine associations between changes in biological characteristics of all life-stages of Atlantic salmon and variations in marine survival ..... 18
2.5.1 Small grilse size and growth during the first summer at sea in Scottish and Norwegian salmon populations ..... 19
2.6 Tracking and tagging studies ..... 19
2.6.1 Acoustic tracking of migrating Atlantic salmon kelts from the LaHave River, Nova Scotia, Canada ..... 19
2.6.2 Monitoring smolt migration in the River Rhine, Germany ..... 20
2.6.3 Data Storage Tags and tagging studies in Iceland ..... 20
2.7 Compilation of tag releases and fin clip data by ICES member countries in 2006 ..... 21
2.8 Summary of the Workshop on the Development and Use of Historical Salmon Tagging Information from Oceanic Areas (WKDUHSTI) ..... 21
3 North-East Atlantic Commission ..... 49
3.1 Status of stocks/exploitation ..... 49
3.2 Management objectives ..... 50
3.3 Reference points ..... 50
3.3.1 Description of the national conservation limits model ..... 50
3.3.2 National conservation limits ..... 50
3.3.3 Progress with setting river-specific conservation limits ..... 51
3.4 Management Advice ..... 51
3.4.1 Northern European maturing 1SW stocks ..... 52
3.4.2 Northern European non-maturing 1SW stocks ..... 52
3.4.3 Southern European maturing 1SW stocks ..... 52
3.4.4 Southern European non-maturing 1SW stocks ..... 52
3.5 Relevant factors to be considered in management ..... 53
3.5.1 Grouping of national stocks ..... 53
3.6 Pre-Fishery Abundance Forecast for 2006-2010 for the Southern NEAC stock complex ..... 54
3.7 Comparison with previous assessment ..... 54
3.7.1 National PFA model and national conservation limit model ..... 54
3.7.2 PFA forecast model ..... 54
3.8 NASCO has requested ICES to describe the key events of the 2006 fisheries and the status of the stocks ..... 55
3.8.1 Fishing at Faroes in 2005/2006 ..... 55
3.8.2 Significant events in NEAC homewater fisheries in 2006 ..... 55
3.8.3 Gear and effort ..... 55
3.8.4 Catches ..... 56
3.8.5 Catch per unit effort (CPUE) ..... 56
3.8.6 Age composition of catches ..... 56
3.8.7 Farmed and ranched salmon in catches ..... 57
3.8.8 National origin of catches ..... 57
3.8.9 The NEAC-PFA model ..... 58
3.8.10 Sensitivity of the PFA model ..... 58
3.8.11 National input to the NEAC-PFA model ..... 58
3.8.12 Description of national stocks as derived from the PFA model ..... 59
3.8.13 Trends in the PFA for NEAC stocks ..... 59
3.8.14 Survival indices for NEAC stocks ..... 60
3.8.15 Exploitation indices for NEAC stocks ..... 60
3.9 NASCO has requested ICES to provide any new information on the extent to which the objectives of any significant management measures introduced in recent years have been achieved ..... 61
3.10 NASCO has requested ICES to provide estimates of by-catch and non- catch fishing mortality of salmon in pelagic fisheries with an assessment of impacts on returns to homewaters ..... 62
3.10.1 SGBYSAL ..... 62
3.10.2 Bycatch of salmon in non-targeted catches in 2006 ..... 62
4 North American Commission ..... 128
4.1 Status of stocks/exploitation ..... 128
4.2 Management objectives ..... 128
4.3 Reference points ..... 128
4.3.1 Conservation Requirements for Labrador ..... 128
4.4 Management advice ..... 129
4.5 Relevant factors to be considered in management ..... 129
4.6 Updated forecast of 2SW maturing fish for 2006 ..... 129
4.6.1 Catch options for 2007 fisheries on 2SW maturing salmon ..... 130
4.7 Catch options for 2008-2010 for non-maturing 1SW ..... 130
4.8 Comparison with previous assessment and advice ..... 130
4.9 NASCO has requested ICES to describe key events of the 2006 fisheries and the status of the stocks ..... 130
4.9.1 Key events of the 2006 fisheries ..... 130
4.9.2 Harvest of North American salmon, expressed as 2SW salmon equivalents ..... 130
4.9.3 Gear and effort. ..... 131
4.9.4 Catches in 2006 ..... 133
4.9.5 Origin and composition of catches ..... 135
4.9.6 Exploitation rates ..... 138
4.9.7 Elaboration on status of stocks ..... 138
4.9.8 Egg depositions in 2006 ..... 142
4.9.9 Marine survival rates ..... 143
4.9.10 Pre-fisheries abundance ..... 144
4.9.11 Summary on status of stocks ..... 146
4.10 NASCO has requested ICES to evaluate the extent to which the objectives of any significant management measures introduced in recent years have been achieved ..... 147
5 Atlantic salmon in the West Greenland Commission ..... 181
5.1 Status of stocks/exploitation ..... 181
5.2 Management objectives ..... 181
5.3 Reference points ..... 181
5.4 Management advice ..... 182
5.4.1 Catch options for West Greenland ..... 182
5.5 Relevant factors to be considered in management ..... 182
5.6 Prefishery abundance forecasts 2007, 2008, 2009 ..... 183
5.6.1 North American stock complex ..... 183
5.6.2 Southern European MSW stock complex ..... 183
5.7 Comparison with previous assessment and advice ..... 183
5.8 NASCO has requested ICES to describe the events of the 2006 fishery and status of the stocks ..... 183
5.8.1 Catch and effort in 2006 ..... 183
5.8.2 Biological characteristics of the catches ..... 184
5.8.3 Continent of origin of catches at West Greenland ..... 184
5.8.4 Elaboration on status of the stocks in the West Greenland Commission area ..... 185
5.9 NASCO has requested ICES to provide a detailed explanation and critical examination of any changes to the models used to provide catch options... ..... 186
5.9.1 Run-reconstruction models ..... 186
5.9.2 Forecast models for pre-fishery abundance of 2SW salmon ..... 186
5.9.3 Development and risk assessment of catch options ..... 186
5.9.4 Critical Evaluation ..... 187
5.10 NASCO has requested ICES to provide any new information on the extent to which the objectives of any significant management measures introduced in recent years have been achieved ..... 187
6 NASCO has requested ICES to identify relevant data deficiencies, monitoring needs and research requirements taking into account NASCO's international Atlantic salmon research board's inventory of on-going research relating to salmon mortality in the sea ..... 205
6.1 Data deficiencies and research needs. ..... 205
Annex 1: Working Documents submitted to the Working Group on North Atlantic Salmon, 2007 ..... 207
Annex 2: References cited ..... 209
Annex 3: List of participants ..... 213
Annex 4: Reported catch of salmon in numbers and weight (tonnes round fresh weight) be sea-age class. Catches reported for 2006 may be provisional. Methods used for estimating age composition given in footnote. ..... 217
Annex 5(i): Estimated numbers of 1SW salmon returns, recruits and spawners for Labrador ..... 225
Annex 6: SAS program code for the provision of catch options for the West Greenland fishery for 2006 to 2008 ..... 237
Annex 7: Glossary of acronyms used by the Working Group on North Atlantic Salmon, 2007 ..... 249
Annex 8: Technical minutes from the ACFM Review Group on Salmon ..... 251

## Executive Summary

- In the North Atlantic, exploitation remains low and nominal catch of Atlantic salmon in 2006 was the lowest in the time series
- Marine survival indices remain low
- The North American Commission 2SW stock complex is suffering reduced reproductive capacity. Factors other than fisheries (marine mortality, fish passage, water quality) are contributing to continued low adult abundance.
- Northern North-East Atlantic Commission stock complexes (1SW and MSW) are at full reproductive capacity prior to the commencement of distant water fisheries
- Southern North-East Atlantic Commission stock complexes (1SW and MSW) are at risk of suffering reduced reproductive capacity prior to the commencement of distant water fisheries
- There are no catch options for the fishery at West Greenland (2007-2009) that would meet the management objectives
- There are no catch options for the fishery at the Faroes (2008-2010) that would meet precautionary management objectives

## 1 Introduction

### 1.1 Main Tasks

At its 2006 Statutory Meeting, ICES resolved (C. Res. 2006/ACFM14) that the Working Group on North Atlantic Salmon [WGNAS] (Chair: T. Sheehan, USA) will meet in Copenhagen, Denmark, from the $11-20^{\text {th }}$ April 2007 to consider questions posed to ICES by the North Atlantic Salmon Conservation Organisation (NASCO). The terms of reference were met and the sections of the report which provide the answers are below:
a ) With respect to Atlantic salmon in the North Atlantic Area:

3 ) provide a framework of indicators which would be used to identify any significant change in the previously provided multi-annual management advice fro each Commission area;

4 ) examine associations between changes in biological characteristics of all life stages of Atlantic salmon and variations in marine survival ${ }^{1}$;

5 ) provide a compilation of tag releases by country in 2006;
2.7

6 ) identify relevant data deficiencies, monitoring needs and research requirements².
Sec 6

2 ) provide any new information on the extent to which the objectives of any significant management measures introduced in recent years have been achieved;

3 ) further develop the age-specific stock conservation limits where possible based upon

4 ) provide annual catch options or alternative management advice for 2008-2010, if possible based on forecasts of PFA for northern and southern stocks, with an assessment of risks relative to the objective of exceeding stock conservation limits and advise on the implications of these options for stock rebuilding ${ }^{4}$;

5 ) provide estimates of by-catch and non-catch fishing mortality of salmon in pelagic fisheries with an assessment of impacts on returns to homewaters.
c ) With respect to Atlantic salmon in the North American Commission area:
1 ) describe the key events of the 2006 fisheries (including the fishery at St Pierre and Miquelon) and the status of the stocks ${ }^{3}$;

2 ) provide any new information on the extent to which the objectives of any significant management measures introduced in recent years have been achieved;

3 ) update age-specific stock conservation limits based on new information as available;
4 ) provide annual catch options or alternative management advice for 2007-2010 with an assessment of risks relative to the objective of exceeding stock conservation limits and advise on the implications of these options for stock rebuilding ${ }^{4}$;

5 ) provide a comprehensive description of coastal fisheries including timing and location of harvest, biological characteristics (size, age, origin) of the catch, and potential impacts on non-local salmon stocks.
d ) With respect to Atlantic salmon in the West Greenland Commission area:
1 ) describe the events of the 2006 fisheries and the status of the stocks ${ }^{3,5}$;
2 ) provide any new information on the extent to which the objectives of any significant management measures introduced in recent years have been achieved;

3 ) provide annual catch options or alternative management advice for 2007-2009 with an assessment of risk relative to the objective of exceeding stock conservation limits and advice on the implications of these options for stock rebuilding ${ }^{4}$

## Notes:

1. There is interest in determining if declines in marine survival coincide with changes in the biological characteristics of juveniles in fresh water or are modifying characteristics of adult fish (size at age, age at maturity, condition, sex ratio, growth rates, etc).
2 NASCO's International Atlantic Salmon Research Board's inventory of on-going research relating to salmon mortality in the sea will be provided to ICES to assist in this task.
3 ICES is asked to provide details of catch, gear, effort, composition and origin of the catch and rates of exploitation. For homewater fisheries, the information provided should indicate the location of the catch in the following categories: in-river; estuarine; and coastal. Any new information on non-catch fishing mortality, of the salmon gear used, and on the by-catch of other species in salmon gear, and on the by-catch of salmon in any existing and new fisheries for other species is also requested.
4 Provide a detailed explanation and critical examination of any changes to the models used to provide catch advice.
5 ICES is requested to provide a brief summary of the status of North American and North-East Atlantic salmon stocks. The detailed information on the status of these stocks should be provided in response to bl and cl.
is provided in Annex 3. A complete list of acronyms used within this document is provided in Annex 7.

| Trial, J. | USA |
| Wennevik, V. | Norway |

### 1.3 Management framework for salmon in the North Atlantic

The advice generated by ICES is in response to terms of reference posed by the North Atlantic Salmon Conservation Organisation (NASCO), pursuant to its role in international management of salmon. NASCO was set up in 1984 by international convention (the Convention for the Conservation of Salmon in the North Atlantic Ocean), with a responsibility for the conservation, restoration, enhancement, and rational management of wild salmon in the North Atlantic. While sovereign states retain their role in the regulation of salmon fisheries for salmon originating from their own rivers, distant water salmon fisheries, such as those at Greenland and Faroes, which take salmon originating from rivers of another Party are regulated by NASCO under the terms of the Convention. NASCO now has seven Parties that are signatories to the Convention, including the EU which represents its Member States.

NASCO discharges these responsibilities via three Commission areas shown below:

### 1.4 Management objectives

NASCO has identified the primary management objective of that organisation as:
"To contribute through consultation and co-operation to the conservation, restoration, enhancement and rational management of salmon stocks taking into account the best scientific advice available".

NASCO further stated that "the Agreement on the Adoption of a Precautionary Approach states that an objective for the management of salmon fisheries is to provide the diversity and abundance of salmon stocks" and NASCOs Standing Committee on the Precautionary Approach interpreted this as being "to maintain both the productive capacity and diversity of salmon stocks" (NASCO, 1998).

NASCO's Action Plan for Application of the Precautionary Approach (NASCO, 1999) provides interpretation of how this is to be achieved, as follows:

- "Management measures should be aimed at maintaining all stocks above their conservation limits by the use of management targets".
- Socio-economic factors could be taken into account in applying the Precautionary Approach to fisheries management issues":
- "The precautionary approach is an integrated approach that requires, inter alia, that stock rebuilding programmes (including as appropriate, habitat improvements, stock enhancement, and fishery management actions) be developed for stocks that are below conservation limits".

### 1.5 Reference points and application of precaution

Conservation limits (CLs) for North Atlantic salmon stock complexes have been defined by ICES as the level of stock (number of spawners) that will achieve long term average maximum sustainable yield (MSY). In many regions of North America, the conservation limits are calculated as the number of spawners required to fully seed the wetted area of the river. In some regions of Europe, pseudo stock-recruitment observations are used to calculate a hockey stick relationship, with the inflection point defining the conservation limits. In the remaining regions, the conservation limits are calculated as the number of spawners that will achieve long-term average maximum sustainable yield (MSY), as derived from the adult-toadult stock and recruitment relationship (Ricker, 1975; ICES, 1993). NASCO has adopted the
region specific conservation limits (NASCO, 1998). These conservation limits are limit reference points ( $\mathrm{S}_{\mathrm{lim}}$ ); having populations fall below these limits should be avoided with high probability.

Management targets have not yet been defined for all North Atlantic salmon stocks. When these have been defined they will play an important role in ICES advice.

For the assessment of the status of stocks and advice on management of national components and geographical groupings of the stock complexes in the NEAC area, where there are no specific management objectives:

- ICES requires that the lower bound of the $95 \%$ confidence interval of the current estimate of spawners is above the CL for the stock to be considered at full reproductive capacity.
- When the lower bound of the confidence limit is below the CL, but the mid point is above, then ICES considers the stock to be at risk of suffering reduced reproductive capacity.
- Finally, when the mid point is below the CL, ICES considers the stock to suffer reduced reproductive capacity.

It should be noted that this is equivalent to the ICES precautionary target reference points $\left(\mathrm{S}_{\mathrm{pa}}\right)$. Therefore, stocks are regarded by ICES as being at full reproductive capacity only if they are above the precautionary target reference point. This approach parallels the use of precautionary reference points used for the provision of catch advice for other fish stocks in the ICES area.

For catch advice on fish exploited at West Greenland (non maturing 1SW fish from North America and non maturing 1SW fish from Southern NEAC), ICES has adopted, a risk level of $75 \%$ (ICES, 2003) as part of an agreed management plan. ICES applies the same level of risk aversion for catch advice for homewater fisheries on the North American stock complex.

## 2 ATLANTIC SALMON IN THE NORTH ATLANTIC AREA

### 2.1 Catches of North Atlantic Salmon

### 2.1.1 Nominal catches of salmon

The nominal catch of a fishery is defined as the round, fresh weight of fish that are caught and retained. Total nominal catches of salmon reported by country in all fisheries for 1960-2006 are given in Table 2.1.1.1. Catch statistics in the North Atlantic also include fish farm escapees and, in some north-east Atlantic countries, relatively small numbers of ranched fish (see Section 2.2.2). Catch and release has become increasingly commonplace in some countries, but these fish do not appear in the nominal catches (see Section 2.1.2).

Icelandic catches have traditionally been split into two separate categories, wild and ranched, reflecting the fact that Iceland has been the only North Atlantic country where large-scale ranching has been undertaken with the specific intention of harvesting all returns at the release site. However, the release of smolts for ranching purposes ceased in Iceland in 1998. While ranching does occur in some other countries, this is on a much smaller scale. Some of these operations are experimental and at others harvesting does not occur solely at the release site. The ranched component in these countries has therefore been included in the nominal catch.

Figure 2.1.1.1 shows the nominal catch data grouped by the following areas: 'Northern Europe’ (Norway, Russia, Finland, Iceland, Sweden and Denmark); 'Southern Europe’ (Ireland, UK (Scotland), UK (England \& Wales), UK (Northern Ireland), France and Spain); 'North America’ (including Canada, USA and St Pierre et Miquelon (France)); and 'Greenland and Faroes'.

The provisional total nominal catch for 2006 was 2001 tonnes, 154 t below the updated catch for $2005(2155 \mathrm{t})$ and the lowest in the time series. The 2006 catch was almost 500 t below the average of the last five years ( 2498 t ), and over 550 t below the average of the last 10 years ( 2554 t ). Catches were below the previous five- and ten-year averages in most countries, and were the lowest recorded in the time series in six countries, four of these in Southern Europe.

Nominal catches in homewater fisheries split, where available, by sea-age or size category are presented in Table 2.1.1.2 (weight only). The data for 2006 are provisional and, as in Table 2.1.1.1, include both wild and reared salmon and fish farm escapees in some countries. A more detailed breakdown, providing both numbers and weight for different sea-age groups for most countries, is provided at Annex 4. Countries use different methods to partition their catches by sea-age class (outlined in the footnotes to Annex 4). The composition of catches in different areas is discussed in more detail in Sections 3, 4, and 5.

ICES recognises that mixed stock fisheries present particular threats to stock status. These fisheries predominantly operate in coastal areas and NASCO specifically requests that the nominal catches in homewater fisheries be partitioned according to whether the catch is taken in coastal, estuarine or riverine areas. Figure 2.1.1.2 presents these data on a country-bycountry basis. It should be noted, however, that the way in which the nominal catch is partitioned among categories varies between countries, particularly for estuarine and coastal fisheries. For example, in some countries these catches are split according to particular gear types and in other countries the split is based on whether fisheries operate inside or outside headlands. A more detailed description of how the catch in Labrador (Canada) is partitioned between coastal and estuarine areas is provided in Section 4.9.5. While it is generally easier to allocate the freshwater (riverine) component of the catch, it should also be noted that catch and release is now in widespread use in several countries (Section 2.1.2) and these fish are excluded from the nominal catch. Noting these caveats, these data are considered to provide the best available indication of catch in these different fishery areas. Figure 2.1.1.2 shows that
there is considerable variability in the distribution of the catch among individual countries. In some countries the entire catch is taken in freshwater, while in other countries the majority of the catch is taken in coastal waters; in many of these the coastal catch has declined markedly over the period.

Coastal, estuarine and riverine catch data aggregated by region are presented in Figure 2.1.1.3. In Northern Europe, catches have fluctuated over the period with no apparent trend. Typically about half the catch has been taken in rivers and half in coastal waters (although there are no coastal fisheries in Iceland and Finland), with estuarine catches representing a negligible component of the catch in this area. In Southern Europe, catches in all fishery areas have declined over the period and, while coastal fisheries make up the largest component of the catch, these fisheries have declined the most, reflecting widespread measures to reduce exploitation in a number of countries.

In North America, the total catch over the period 2000-2006 has been relatively constant. The majority of the catch in this area has been taken in riverine fisheries, while the catch in coastal fisheries has been relatively small in any year ( 11 t or less). Catches in coastal and estuarine fisheries, predominantly from aboriginal food fisheries, have increased slightly over the period.

### 2.1.2 Catch and release

The practice of catch and release in rod fisheries has become increasingly common as a salmon management/conservation measure in light of the widespread decline in salmon abundance in the North Atlantic. In some areas of Canada and USA, catch and release has been practiced since 1984, and in more recent years it has also been widely used in many European countries both as a result of statutory regulation and through voluntary practice.

The nominal catches presented in Section 2.1.1 do not include salmon that have been caught and released. Table 2.1.2.1 presents catch-and-release information from 1991 to 2006 for nine countries that have records; catch and release may also be practiced in other countries while not being formally recorded (e.g. Norway). There are large differences in the percentage of the total rod catch that is released: in 2006 this ranged from $18 \%$ in Iceland to $82 \%$ in Russia, reflecting varying management practices and angler attitudes among these countries. Within countries, the percentage of fish released has tended to increase over time. Overall, almost 154000 salmon were reported to have been released around the North Atlantic in 2006, about 3000 less than in 2005. There is also evidence from some countries that larger MSW fish are released in higher proportions than smaller MSW fish. Whilst the use of catch and release is likely to result in some fish dying through exhaustion or damage, studies have demonstrated that if fish are appropriately handled, mortality following capture is low and a large proportion of fish survive to spawn (Dempson et al., 2002; Webb, 1998a, 1998b; Whoriskey et al., 2000).

### 2.1.3 Unreported catches

Unreported catches by year (1987-2006) and Commission Area are presented in Table 2.1.3.1. A description of the methods used to derive the unreported catches was provided in ICES (2000) and updated for the NEAC Region in ICES (2002). In practice, the derivation methods used by each country have remained relatively unchanged and thus comparisons over time may be appropriate. However, the estimation procedures vary markedly between countries. For example, some countries include only illegally caught fish in the unreported catch, while other countries include estimates of unreported catch by legal gear as well as illegal catches in their estimates. Over recent years efforts have been made to reduce the level of unreported catch in a number of countries (e.g. through improved reporting procedures and the introduction of carcase tagging and logbook schemes).

The total unreported catch in NASCO areas in 2006 was estimated to be 670 t , a decrease of $4 \%$ from 2005 ( 700 t ). The unreported catch in the North East Atlantic Commission Area in 2006 was estimated at 604 t , that for the North American Commission Area 56 t , with 10 t estimated for the West Greenland Commission Area. The unreported catch, expressed as a percentage of the total North Atlantic catch (nominal and unreported), has fluctuated since 1987 (range 23-34\%), but has remained fairly constant at around $25 \%$ in the last three years (Figure 2.1.3.1). Expressed as a percentage of the total North Atlantic catch, estimates by country range from 0 to $15 \%$ in 2006 (Table 2.1.3.2), and expressed as a percentage of national catches, unreported catches range between $1 \%$ and $50 \%$.

In the past, salmon fishing by non-contracting parties is known to have taken place in international waters to the north of the Faroe Islands. Typically, a number of surveillance flights have taken place over this area in recent years. These have resulted in no sightings of vessels, although there have been extended periods over the winter period when no flights took place. This is the period when salmon fishing has previously been reported. No information was available regarding surveillance flights in 2006.

### 2.2 Farming and Sea Ranching of Atlantic Salmon

### 2.2.1 Production of farmed Atlantic salmon

The provisional estimate of farmed Atlantic salmon production in the North Atlantic area for 2006 is 817100 t . This represents a small increase on 2005, but remains below the peak figure of 831075 t reported for 2004 (Table 2.2.1.1 and Figure 2.2.1.1). Most of the North Atlantic production took place in Norway (73\%) and UK (Scotland) (17\%).

World-wide production of farmed Atlantic salmon has been in excess of one million tonnes since 2002. However, it is difficult to source reliable production figures for all countries outside the North Atlantic area and it has been necessary to use 2005 estimates for some countries in deriving a world-wide estimate for 2006. Noting this caveat, total production in 2006 is provisionally estimated at around 1264000 tonnes (Table 2.2.1.1 and Figure 2.2.1.1), a small increase on 2005 and the highest in the time series. Production outside the North Atlantic is dominated by Chile and is estimated to have accounted for $35 \%$ of the total in 2006. World-wide production of farmed Atlantic salmon in 2006 was thus over 630 times the reported nominal catch of Atlantic salmon in the North Atlantic. Farmed salmon therefore dominate world markets.

### 2.2.2 Harvest of ranched Atlantic salmon

Ranching has been defined as the production of salmon through smolt releases with the intent of harvesting the total population that returns to freshwater (harvesting can include fish collected for broodstock) (ICES, 1994). The total harvest of ranched Atlantic salmon in countries bordering the North Atlantic in 2006 was 9 t, a slight increase on 2005 (Figure 2.2.2.1). Salmon ranching (smolt releases) ceased in Iceland in 1998. Small catches of ranched fish were recorded in each of the three other countries reporting such fish (Ireland, UK (N. Ireland) and Norway); the data includes catches in net, trap and rod fisheries.

### 2.3 NASCO has asked ICES to report on significant, new or emerging threats to, or opportunities for, salmon conservation and management

### 2.3.1 Recovery potential of Bay of Fundy and Southern Upland salmon populations

The Working Group reviewed a model being used to assess how salmon populations are expected to respond to recovery activities in the Scotia-Fundy Region of Canada. The model is
based on the idea that human activities may affect some part or parts of a population's life history. This in turn affects the population's productivity which then affects population size. The effects of an activity are evaluated by examining the expected change in population size in response to the activity.

An equilibrium modeling approach was used for this analysis. This kind of analysis begins by splitting the life cycle into two parts, and for a given set of life history parameters, determining the population size at which the rates in each part of the life cycle are balanced such that the population doesn't increase or decrease in size. In the analyses presented, the first part of the model gives the number of smolts produced as a function of egg deposition (Figure 2.3.1.1a), modeled using a Beverton-Holt function. This model has two parameters, the slope of the function at the origin and the carrying capacity of the river, which can be changed in response to human activities in freshwater. The second part, the egg-per-smolt relationship (Figure 2.3.1.1b), which gives the rate at which smolts were expected to produce eggs in their entire life, is calculated based on survival of juvenile salmon in the marine environment, age-at-maturity, fishing mortality, fecundity, and the number of times a fish spawns throughout its life. The population equilibrium is found by estimating the abundance at which the production of smolts by eggs equals the reciprocal of the production of eggs by smolts (Figure 2.3.1.1c). In the example, a decrease in smolt-to-adult survival shifts the equilibrium point to a smaller population size. If smolt-to-adult survival decreases far enough, the equilibrium population size goes to zero and the population will become extinct in the absence of human intervention or a change in one or more of the vital rates. However, an equilibrium population size greater than zero does not necessarily mean that a population will not go extinct, because no allowance is made for random variability in the life history parameters.

The Working Group examined four case studies, two of which are reproduced here. For two populations, such as the LaHave River, Nova Scotia, only a single threat was examined. Population specific data were available for this population. Freshwater production in this river appears good relative to some other rivers in the region. Return rates for this population averaged $2.37 \%$ (range: $1.09 \%$ to $4.33 \%$ ) for 1 SW salmon and $0.48 \%$ (range: $0.24 \%$ to $0.97 \%)$. for 2 SW salmon for the 1996 to 2004 smolt year classes. The population equilibrium, based on average at-sea survival rates for the period, is just over $50 \%$ the conservation requirement (Figure 2.3.1.2.). At the lowest at-sea survival rates observed during this period, the population is not viable, whereas at the highest rates observed, the population equilibrium is well above the conservation requirement for this river.

Two of the case studies illustrated the cumulative effects of multiple threats. In the West River (Sheet Harbour, Nova Scotia) case study (Figure 2.3.1.3), little population specific data exists so the model was developed using a combination of data from the LaHave River and information about habitat specific to the river. Besides low at-sea survival, West River is also impacted by acidification. The model illustrates that a small population may be achieved in this river if marine survival improves, the population would be expected to remain below its conservation requirement and may be below a size at which the population would be viable in the long term. Both an increase in at-sea survival and pH recovery is needed to increase this population to levels above its conservation requirement.

The Working Group concluded that the approach was useful for evaluating the potential for recovery of salmon populations. Assuming that conditions in freshwater are not responsible for the low marine survival being experienced by Scotia-Fundy populations, the case studies illustrate the limiting effect that low marine survival can have on recovery actions focused only on improving freshwater habitat. However, at high at-sea survival rates the equilibrium population size is very sensitive to the amount of freshwater habitat. The LaHave River case study showed that in recent years, at-sea survival rates have in some years been high enough that if sustained, populations would be expected to increase to levels above the conservation
spawner requirement given sufficient freshwater habitat. In these instances, recovery actions focused in freshwater may or may not be effective depending on the scope available for improvements in freshwater. The case studies also illustrated how freshwater habitat degradation such as acidification limits the potential for population growth in some rivers even if at-sea survival improves. The analyses reviewed could be extended to other populations and threats, however, within the Scotia-Fundy region, the extent of all threats is not fully quantified. For this reason, the expected population response throughout the region to an increase in at-sea survival is presently unknown.

### 2.3.2 Monitoring interactions between aquaculture and wild fisheries in Norway

## Ongoing Research

A number of studies have been performed by the Institute of Marine Research (IMR), Norway to assess the impact of salmon farming in marine areas where important wild salmon populations may pass, and to enable appropriate actions to be taken to alleviate possible negative effects from the aquaculture activities. These studies clearly indicate that the impact from salmon lice infestations occurring in the migration areas of wild postsmolts may directly influence mortality rates but may also indirectly affect mortalities through reducing growth rates of fish surviving the first infestations (Skilbrei and Wennevik, 2006a).

## Studies relevant to regulations and management

Experimental trawling for wild postsmolts and hatchery postsmolts placed in cages along a fjord have demonstrated that a combination of enforcement of aquaculture regulations, and a strict programme of sea lice monitoring in fish pens together with voluntary actions from the farmers appears to reduce the numbers of sea lice to stated tolerance levels (Boxaspen 2006; Finstad et al., 2007). However, the continued increase in the number of fish farms and production of aquaculture highlight the importance of continued monitoring and surveillance.

Capture fisheries examined following simulated escapes of aquaculture salmon suggest a low probability of successful recapture after a major escape, unless the fisheries are operated immediately (within a few days) and with the effort spread over a large area. The study showed that escapees can be dispersed over several square kilometres in the course of just a few days (Skilbrei et al., 2007). In addition, immediately after an "escape" the fish may be in the deeper water layers avoiding capture by many gear types. After the initial period, surface gears may be more effective as the fish may be present on the surface.

These behavioural patterns of the escapees suggest that recapture efforts should be regional rather than local. In one experiment, more than $50 \%$ of adult salmon tagged with acoustic tags were recovered in several recreational fisheries with most of them taken in the recreational net fisheries during the annual autumn fishery for escapees. Recoveries indicated that most of the tagged salmon were caught within a range of 20 kilometres from the release sites indicating that high recapture rates are possible in fjord regions if the fishing effort is high. In sparsely populated areas, the efforts and resources required to recapture escapee salmon may be large. This includes farm sites close to the open sea where the salmon are believed to spread even faster than in the fjords as well as after very large escape incidents (Skilbrei and Wennevik, 2006b; Skilbrei et al., 2007).

## Identification methods

Norwegian fish farmers are required to report escapes from their farms to the authorities. However, it may be some time before it is apparent that fish have escaped, and such events are often discovered by nearby fishermen who report sudden and unusually high numbers of salmon in their gear. Recently a Norwegian project (TRACES) aimed at investigating the
origin of salmon from unreported escapes to their farm of origin, has made a major breakthrough in identifying the specific farm or cage of origin of escapee salmon by using a combination of genetic and chemical characteristics. In autumn 2006, substantial numbers of escaped salmon were observed in a fjord in Western Norway, although none of the fish farmers in the area had reported any escapes. The Institute of Marine Research was asked by the Directorate of Fisheries to investigate whether the source of the escaped fish could be traced. Samples were collected from all net cages in fish farms in the fjord and analyzed for 15 microsatellites. The DNA and chemical profiles of the escaped fish were then compared to the profiles of the different fish farms. The results showed with high probability that the escapees originated from one specific net cage. As this was the first time that DNA methodology had been used to trace the origin of escaped fish with such confidence that the Directorate of Fisheries in Norway proposes to apply similar procedures in similar cases in the future.

## Research reports

The Working Group noted that the proceedings (Hutchinson, 2006) and the Conveners’ report (Hansen and Windsor, 2006) from the ICES and NASCO Symposium on Interactions between aquaculture and wild stocks of Atlantic salmon and other diadromous fish species: Science and Management, Challenges and Solutions have been published.

### 2.3.3 Cessation of mixed stock fisheries in Irish coastal waters from 2007

In 2005, an Irish Government decision was taken to end the at sea mixed stock fisheries (predominantly drift nets) in 2007 and to operate fisheries only on single river stocks, which were shown to be meeting conservation limits. This was to align with best international practice, comply with scientific advice from ICES, meet NASCO objectives and to afford greater protection to stocks designated under the EU Habitats Directive (Council Directive 92/43/EC;
http://ec.europa.eu/environment/nature/nature_conservation/eu_nature_legislation/habitats_dir ective/index_en.htm). In the absence of mixed stock fisheries at sea from 2007, the methodology used to provide status of river stocks and catch advice has been modified for 2007 and thereafter. The major differences are related to the provision of catch advice on a river specific basis as advised by the Standing Scientific Committee of the National Salmon Commission. In so doing, the status of stocks is related specifically to individual rivers rather than to district aggregations of stocks. In the absence of a drift net fishery (or any other net fishery) at sea, in-river measures of abundance have been used (i.e. fish counter data and rod catch data) to provide a primary measure of spawning stocks and attainment of conservation limits.

The process of estimating conservation limits remains unchanged, as does the assessment of whether the stock (in this case the river stocks rather than the district stock as calculated in previous years) is above or below its conservation limit. This eliminates the uncertainty associated with the previous assessment in assigning all fish in the district catch to rivers within that district.

In this manner fisheries will now only take place on single river stocks shown to be meeting conservation limits in 43 rivers with the catch level set to allow at least a $75 \%$ chance of meeting the conservation limit. There are also two estuarine fisheries identified where there is a catch option providing a $75 \%$ chance that the individual rivers entering the estuary will meet their conservation limits.

There are 34 rivers that do not have an identifiable surplus over the CL. Therefore, there are no harvest options available to allow a fishery to take place such that these stocks will meet their conservation limit. Where these rivers are meeting $65 \%$ or more of their conservation limit a directed catch and release fishery will be permitted, provided the regional fisheries
authorities are satisfied that this will comply with set criteria and survival of released fish is within published limits.

There are 74 small rivers with no counter or an average rod catch of less than 10 salmon per annum. Given the tenuous state of many of the smaller rivers, general advice is that there should be no directed fishery (including catch and release) until other information is made available to indicate that these rivers are exceeding their CL and that there is a catch option that meets the management objectives.

### 2.3.4 Development of predictive models for returning salmon in Norway

A project to develop predictive models for the return of Norwegian salmon has recently been completed. The factors examined included hydrography, plankton production, the biomass and condition of pelagic marine fish species and salmon growth and survival indices (e.g. catches, estimated marine survival rates).

Models to forecast 1SW salmon were developed from environmental variables, plankton production, and condition factor and biomass of herring. This approach is based on the assumption that the smolt production is the same every year. To forecast PFA of 1SW salmon a multivariate regression method called PLS (Projection on Latent Structures, Martens and Martens, 2001) was applied. PLS models both the predictors and the response (1SW return) simultaneously to find the latent structures in the predictor space that best explain the response. These latent structures are similar to principal components. Models were developed for the whole of Norway, for the three regions (South-, Mid- and North-Norway) and for a single river (River Drammen). For all models, except South Norway, it was found that total stock biomass of herring was the most influential predictor.

Models were developed to forecast PFA of 2SW and 3SW salmon in years $\mathrm{i}+1$ and $\mathrm{i}+2$ based on the run of 1SW fish in year i. This approach is independent of smolt production and was based on observations of significant correlations between survival indices of 2SW and 3SW salmon from the same smolt cohorts.

The precision of the forecasts was variable, lowest in southern Norway and highest in northern Norway. This has been the first approach to forecast salmon runs to Norway, and work is continuing to further develop the models, including standardising data sampling so that the quality of appropriate time series will be less variable. It is hoped this will improve the ability to predict homewater PFA .

### 2.3.5 Human activities impacting on aquatic diversity

There are concerns about the movement and introduction of exotic fish (e.g. carp) to nonendemic watersheds and the impacts of these introductions on Atlantic salmon stocks. The inadvertent movement and introduction of aquatic diseases and organisms by human activities, including fishing, can also occur and potentially impact salmon populations and resource users. The Working Group was informed of the first confirmed occurrence of a presumably non-native freshwater algae in a salmon river of eastern Canada.

Didymosphenia geminata, commonly referred to as "didymo" or "rock-snot", is a fresh water diatomous algae that attaches to rocks and grows on gelatinous stalks. It prefers waters of low nutrient levels. It can develop into large mats of yellow-brown colour, which can cover the bottom of rivers and lakes. The mats have the texture of wet wool and when dry have the appearance of toilet paper or parchment paper. Didymo is not toxic and its impacts are most important on the aesthetics of the rivers (including angling quality). More detailed information and references on the characteristics of didymo can be found at the website of the Invasive Species Specialist Group (ISSG) of IUCN Species Survival Commission (http://www.issg.org/database/species/ecology.asp?si=775\&fr=1\&sts=).

Since the late 1980s, didymo blooms have been reported in a number of northern hemisphere countries within Europe and North America. Recently, didymo was also introduced to New Zealand where its impact on rivers has been severe resulting in a strong and directed campaign by the government to control its further distribution (see http://www.biosecurity.govt.nz/didymo).

The first important occurrence in eastern Canada was confirmed in the Matapedia River (Quebec) in 2006. The proliferation occurred in a high use prime angling stretch of the river and raised alarms in the local community. From water samples obtained in November 2006, cells of didymo were identified from seven of thirteen sampled rivers within Quebec, although the only important proliferation was reported from the Matapedia River.

In Iceland, didymo was not identified from aquatic surveys dating back to 1940's but it was subsequently identified in samples from 1994 from several rivers (Jonsson et al., 2000). In some rivers, blooms of didymo were reported and the algae spread to many rivers in the following years. It seems that shortly after it first arrives in a river or to an area in a river it can have very dense growth, but generally retreats after a few years although it still persists. It is now spread around the entire coast of Iceland, though not in all rivers. There have been no documented impacts on salmon or trout populations in Iceland.

Didymo can be transferred between watersheds through various vectors including fishing gear and more specifically the felt soles on waders. The increased spread of didymo in the last two decades is hypothesized to be the result of increasing global travel of recreational water users, including anglers.

The inadvertent transfer of didymo and other aquatic biota can be easily controlled through cleaning of gear using readily available detergents followed by drying equipment. Information campaigns to educate all water resource users have developed in eastern Canada. It is primarily through increased awareness and directed effort by all users that the spread of didymo and other aquatic invasive species can be controlled.

The Working Group notes that the impacts of non-indigenous species on Atlantic salmon populations are not fully understood and that the incidence of exotic species in aquatic habitats appears to be increasing.

### 2.3.6 Timing and nature of density dependence in Atlantic Province salmon populations

The Working Group examined a paper on the timing and nature of density dependence in Atlantic Province (Eastern Canada) salmon populations. Density dependence is the regulatory mechanism that prevents populations from increasing without bound or routinely extirpating. Analyses of density dependence are an important step in model development for reference point estimation, assessment of extinction risk and evaluating the effectiveness of proposed recovery activities as used in Section 2.3.1. Density-dependent survival within freshwater was analysed using electrofishing data from nine populations in the Maritime Provinces and smolt-to-adult return-rate data from 15 populations in eastern Canada was used to evaluate whether density-dependence is important in the marine environment. As illustrated with data and fits for three of the populations in Figure 2.3.6.1, three spawner-recruit models, a Beverton-Holt, a Ricker and a one-parameter density-independent model, were fit to each data series using maximum likelihood. Model fits were compared using likelihood ratio tests.

Within fresh water, no single, unequivocal pattern was evident with respect to the timing of density dependence. Density dependence was detected in three of six egg-to-age-0 transitions, in six of nine age-0-to-age-1 transitions, and in three of the nine age-1-to-age-2 comparisons. Overcompensation was not detected in these data. Carrying capacity for age-1 salmon was found to be highly variable among populations. Using a mixed-effects model, the median
carrying capacity was estimated to be 24.8 parr/ $100 \mathrm{~m}^{2}$ with $95 \%$ of the probability density falling between 3.8 and 165.9 parr/ $100 \mathrm{~m}^{2}$ (Figure 2.3.6.2).

In the marine environment, density dependence was potentially detected in three of the 15 populations for 1SW salmon, but these three series were either short or highly variable. Density dependence was not detected in any of nine 2 SW salmon populations.

The variability in both the timing of density dependence and carrying capacity for parr highlights the need for population-specific data for establishing reference points or when planning recovery or enhancement activities. The three populations with the lowest estimated age- 1 carrying capacity are located in the outer Bay of Fundy and Southern Upland, are in the southern half of the range of the included populations and are populations with low at-sea survival. Assuming these estimates are correct, freshwater production has the potential to limit population growth in these populations even if at-sea survival improves.

### 2.3.7 Autumn downstream migration of juvenile Atlantic salmon in the UK possible implications for the assessment and management of stocks

Downstream movement of juvenile Atlantic salmon during the autumn has previously been recorded for populations in both North America and the UK (Youngson, et al., 1983; Riley et al., 2002). Although Cunjak and Chadwick (1989) reported a significant migration into tidal rearing habitats, the function of this movement, the physiological status of these fish and whether such fish make an early entry into the marine environment remains unclear. The Working Group received new information from a study undertaken in the River Frome (Pinder et al., in press), which sought to quantify the size of the autumn migration and determine the physiological status of both migrants and non-migrants in this catchment.

Large numbers of 0+ salmon parr were tagged in the Frome during September in both 2004 and 2005 with Passive Integrated Transponder (PIT) tags; the majority of salmon leave this river as one-year-old smolts. The subsequent movements of the tagged fish were monitored at a number of trapping facilities and by means of a full river PIT antenna detector array (Ibbotson et al., 2004) located 4 km above the head of tide. The number of autumn migrants passing the antenna array between October 2005 and January 2006 was estimated at 2480 fish. This compares with a three-year mean smolt run estimate for the river (2004-06) of 9400. Electrofishing at low water in tidal sections of the river in February and March subsequently confirmed the presence of autumn migrating parr in the estuary.

Elevated total thyroxine levels (T3 and T4) in the autumn migrants were indicative of the fish making a directed migration. Further, increased numbers of filament chloride cells and higher percentage cover of the gill epithelium by these cells in the estuarine resident fish compared with freshwater residents, also suggested increased salinity tolerance and ability to osmoregulate. However, this was not sufficient for the estuarine residents to survive a saltwater challenge test (performed in February/ March). Neither the autumn migrants, estuarine resident parr nor river residents displayed a significant increase in gill or kidney $\mathrm{Na}+$, $\mathrm{K}+$-ATPase activity, as was evident for smolts in the springtime (Figure 2.3.7.1).

It was concluded that the component of the population that migrated downstream in the autumn was not physiologically adapted to survive early entry into saltwater and was expected to remain in the lower river/estuary at least until the following spring. It is not clear whether the downstream migration reflects displacement from upstream areas or is a specific life history strategy. It is also not known whether marine survival varies between autumn and spring migrants. Future returns of PIT-tagged adult salmon to the Frome should provide new information in this context.

The extent to which autumn migration might vary between catchments or over time, for example in response to climate change, is unclear. However, the implications from this study,
that a sizeable proportion of the parr population over winters in the estuary, highlights the importance of regarding estuarine environments as habitats utilised by juvenile salmon and of managing such habitats accordingly. Further, the findings may have implications for stock assessment programmes, as autumn migrants are likely to be excluded from most current smolt run estimates and estimates of marine survival.

### 2.4 NASCO has asked ICES to provide a framework of indicators which would be used to identify any significant change in the previously provided multi-annual management advice for each Commission area.

### 2.4.1 Study Group on Establishing a Framework of Indicators of Salmon Stock Abundance

In 2006, ICES provided multi-annual management advice for all three NASCO Commission Areas and presented a preliminary framework (Framework of Indicators) which would indicate if any significant change in the previously provided multi-annual management advice in subsequent years had occurred. The advice and Framework of Indicators (FWI) formed the basis for the multi-annual (3 year) regulatory measures, which were agreed upon in the West Greenland (salmon fishery in the waters off West Greenland; NASCO, 2006a) and North-East Atlantic Commissions (salmon fishery in Faroese waters; NASCO, 2006b). The second and third year of the regulatory measures for both fisheries is dependant on ICES providing, and the Parties to each Commission Area accepting, a finalized Framework of Indicators.

ICES formed the Study Group on Establishing a Framework of Indicators of Salmon Stock Abundance (SGEFISSA, ICES, 2007a) which met in 2006. The SGEFISSA further developed the FWI, which was originally presented by ICES (ICES, 2006). The FWI defined a significant change in management advice as an unforeseen increase in stock abundance to a level that would allow a fishery. The SGEFISSA developed a generalized FWI that can be applied to each NASCO Commission Area. Further, the SGEFISSA developed a FWI for the Greenland fishery based on the seven contributing stock complexes with direct links to the three management objectives established by NASCO for that fishery. This FWI assesses if there is an expectation that the previously provided management advice for the Greenland fishery is likely to change in subsequent years. The SGEFISSA provided a spreadsheet template FWI (Greenland Fishery Framework of Indicators.xls) in which the underlying variable of interest/ indicator dataset relationships and decision rules are summarized and collated according to the specific management objectives for each fishery. To apply the FWI, a user must enter the indicator values for the most recent year and the required fields are automatically calculated, displayed, summarized in a stock-specific fashion and an overall recommendation is determined.

The SGEFISSA was unable to develop a spreadsheet FWI for the Faroese fishery for a number of different reasons. Among them is the lack of quantitative catch advice, the absence of specific management objectives for the fishery, the absence of a sharing agreement for this fishery, and that none of the available indicator datasets met the criteria for inclusion in the FWI. In addition, the stock complex that is currently limiting this fishery (Southern NEAC non-maturing complex) has fluctuated around its Spawner Escapement Reserve in recent years.

The Working Group endorsed the SGEFISSA report of applying the FWI in respect of the West Greenland and North American Commissions. However, in the absence of a FWI for the Faroese fishery, the Working Group recommends that annual assessments be conducted to verify the multi-year catch advice.

### 2.4.2 Update of the Framework of Indicators for the 2007 to 2009 multi-year catch advice at West Greenland

The Working Group updated the FWI for the Greenland fishery. The update consisted of:

- Adding the values of the indicator variables for the most recent year,
- Running the objective function spreadsheet for each indicator variable and the variable of interest relative to the management objectives,
- Quantifying the threshold value for the indicator variables and the probabilities of a true high state and a true low state for those indicator variables retained for the framework,
- Revising/adding the indicator variables and the functions for evaluating the indicator score to the framework spreadsheet, and
- Providing the spreadsheet for doing the framework of indicators assessment.

The variables of interest data series for the six geographic areas of North America and for the southern NEAC MSW complex are presented in Table 2.4.2.1. The management objectives for the development of the catch options for the West Greenland fishery are presented in Table 2.4.2.2.

A total of 82 indicator variables were updated and analysed using the objective function spreadsheet. These variables included returns of 1SW or small salmon, 2SW or large salmon, and return rates as 1SW and 2SW salmon of wild and hatchery origin fish.

For the North American Commission area, the indicator variable data sets originated from 38 rivers distributed from the US to Labrador (Figure 2.4.2.1).

Based on the objective function spreadsheet and the criteria established by the SGEFISSA, a total of 32 indicator variables were retained (see below). Of these, four were return rate indicators of hatchery fish, while the remainder were of wild 2SW or large salmon ( $\mathrm{N}=15$ ) and wild 1SW or small salmon ( $\mathrm{N}=13$ ) returns to rivers.

| SUMMARY Of INDICATOR VARIABLES RETAINED FROM NORTH AMERICA |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Origin | Wild | Wild | Wild | Wild | Hatchery | Hatchery |  |
| Type of data | Return | Return | Survival | Survival | Survival | Survival |  |
| SIzE/AGE GRoup | Small/1SW | Large/2SW/ <br> MSW | Small/1SW | Large/2SW | Small/1SW | Large/2SW | Total |
| Labrador |  |  |  |  |  |  | 0 |
| Newfoundland | 1 |  |  |  |  |  | 1 |
| Quebec | 6 | 8 |  |  |  |  | 14 |
| Gulf | 1 | 1 |  |  |  |  | 2 |
| Scotia-Fundy | 4 | 4 |  |  | 1 | 1 | 10 |
| US $^{1}$ | 1 | 2 |  |  | 1 | 1 | 5 |
| Total | 13 | 15 |  |  | 2 | 2 | $\mathbf{3 2}$ |

${ }^{1}$ for US, returns include both wild and hatchery origin fish
${ }^{2}$ in one river (Narraguagus), returns are of age/size groups combined
Summaries of the indicator variables retained for the 2007 to 2009 multi-year catch advice indicator framework are provided in Table 2.4.2.3. No indicator variables were retained for the Labrador area and for southern NEAC non-maturing complex. All the retained indicator variables had a probability of identifying a true low state or a true high state of at least $80 \%$ (Figure 2.4.2.2). For the Quebec area, two indicator variables met the criteria for retention as described in SGEFISSA but the probability of identifying either a true low state or a true high
state was less than $80 \%$ and the Working Group recommended that these indicators not be included in the framework.

The Working Group modified the FWI from a one-way test to a two-way test in order to evaluate the over-estimation of stock abundance by the forecast model.

### 2.4.3 Application of the framework indicator spreadsheet for signalling whether a significant change in management advice may occur for the fisheries in 2008 and 2009.

The FWI spreadsheet is shown in Figure 2.4.3.1. The framework provides one of two conclusions for the user:

1) no significant change identified by the indicators

2 ) reassess
If no significant change has been identified by the indicators, then the multi-year catch advice for the year of interest could be retained. If a significant change is signalled by the indicators, the response is to reassess.

The framework spreadsheet is designed to capture both fishing and non-fishing scenarios:

- multi-year advice provides no catch options greater than zero but indicators are suggesting that the management objectives may be met (conclusion: Reassess),
- multi-year advice provides catch options greater than zero but the indicators suggest the management objectives may not be met (conclusion: Reassess).

The FWI spreadsheet will be updated with the returns or return rate data for 2007 to evaluate the appropriateness of the 2008 advice, and with the returns or return rate data for 2008 to evaluate the appropriateness of the 2009 advice. It is anticipated that the data for the indicator variables to populate the framework would be available in January of the year of interest. The framework will be updated whenever a new set of multi-year catch advice is provided. Figure 2.4.3.2 illustrates the timeline of how the FWI would operate.

## Applying the framework

There are two steps required by the user to run the framework. The first step in the framework evaluation is to enter the catch advice option for the West Greenland fishery ( t ). This feature provides the two way evaluation of whether a change in management advice may be expected and a reassessment would be required. The second step is to enter the values for the indicator variables in the framework for the year of interest. The spreadsheet evaluation update is automated and the conclusion is shown in the row underneath "Overall Recommendation".

## Framework features

The framework spreadsheet contains a number of cells with quantities used to evaluate the indicator variables and the attainment of management objectives. This information could be used to evaluate in a qualitative sense the state of the river-specific salmon stocks relative to the threshold values, which would infer that the management objectives would be met or not met for the geographic area. An understanding of these variables is not required to run the framework spreadsheet, as they are locked and not available to the user.

The conclusions from the framework evaluation are based on whether there is simultaneous achievement of the management objectives in the six stock areas of North America and the southern NEAC non-maturing complex (Figure 2.4.3.1). If there are no indicator variables for a geographic area, the attainment of the management objectives is evaluated as unknown and that area or complex is not used in the decision structure of the framework.

Within the geographic areas for which indicator variables are retained, all the available indicators are used to assess the indicator score. If an update value for an indicator variable is not available for the year of interest evaluation, the indicator variable is not used to quantify the indicator score for that area.

The indicator variables within a geographic area may be in different indicator states relative to the achievement of the management objective for the area. For example, in Figure 2.4.3.1 for the Quebec area, the indicator variable defined as the large salmon returns to River Bonaventure suggests that the management objective for Quebec may be met (indicator score $=+1$ ) but the next indicator variable (large returns to Grande Riviere) suggests that the management objective will not be met (indicator score $=-1$ ).

The overall indicator score for the geographic area is used to determine if the management objectives could be met. Multiple indicators within the stock complex groupings are combined by arithmetic average of the product of the indicator value $(-1,+1)$ and the probability of a correct assignment corresponding to the true low or true high states. An average geographic area or stock complex score equal to or greater than zero would suggest there is a likelihood of meeting the management objective for that grouping based on the historic relation between the variable of interest (adult returns to a geographic area or PFA) and the indicators evaluated. An indicator variable with a very strong power of resolution for a true low or true high state (for example geographic area Scotia-Fundy, LaHave River large salmon returns, probability of true low $=100 \%$, probability of a true high $=100 \%$ ) will have more weight in the derivation of the area score than an indicator variable of lower resolving power (for example geographic area Scotia-Fundy, Saint John 1SW Rate for hatchery, probability of true low $=81 \%$, probability of true high = 87\%) (Figure 2.4.3.1).

### 2.5 NASCO has asked ICES to examine associations between changes in biological characteristics of all life-stages of Atlantic salmon and variations in marine survival

The purpose of examining these associations is to determine whether declines in marine survival coincide with changes in the biological characteristics of juveniles in fresh water or are related to characteristics of adult fish (size at age, age at maturity, condition, sex ratio, growth rates, etc.). Changes in the sea age composition and run timing of salmon have been widely reported for populations throughout the North Atlantic, commonly involving a progressive reduction in the proportion of older fish and an associated shift in run timing from spring-summer to summer-autumn. In addition, the Working Group noted that there was also increasing evidence for changes in other biological characteristics, for example the size and growth of parr and the mean smolt age.

The Working Group received new information on changes in the size and growth of 1SW fish in the North East Atlantic and in biological characteristics from two index rivers in Quebec, but were unable to consider this topic in depth in the time available. The Working Group recommends that co-ordinated efforts are made to collate information on biological characteristics throughout the geographic range, to include issues such as:

- Juvenile size at age (freshwater growth)
- Smolt age composition
- Smolt run timing (and autumn parr movements)
- Post-smolt growth
- Sea-age composition
- $\quad$ Size at return (marine growth)
- Adult run timing
- Sex ratios

### 2.5.1 Small grilse size and growth during the first summer at sea in Scottish and Norwegian salmon populations.

Sample data from three Scottish net fisheries suggest that, over a wide area of Scotland and in each month of the season where data were available, grilse returning in 2006 were both substantially shorter and lighter than previous baseline data. Samples from river fisheries in Southern Norway show a similar pattern, while in mid and northern Norway the grilse sizes in 2006 were closer to the average in the period 1989-2005. The Scottish data show that the existence of "small grilse" was the result of a general decline in the size of returning fish as a whole. Reports of small grilse were simply the most obvious manifestations of a sharp decline in the general size of fish returning in 2006 compared to previous years.

Analysis of the back-calculated lengths of fish from scale samples from the North Esk net \& coble fishery provides strong evidence for a substantial decline in the growth of the 2006 grilse either in the short period in freshwater before smolt emigration or, more likely, in the post-smolt phase of their life in 2005. Back-calculated lengths of first year growth of grilse from rivers in the South Western part of Norway also show that the growth of the 2005 smolt cohort had declined substantially compared to the growth of previous cohorts.

Analysis of the time series data for all six Scottish net fisheries indicates that both median fork length and fresh round weight of returning grilse show distinct declines over a 40-year time period, albeit with shorter time-scale variations also evident within the data set. Data for 2006 show a sharp decline, particularly in July and August. In rivers in the southern parts of Norway the mean weight of grilse (fish smaller than 3 kg ) had varied since 1989, with 2006 showing the lowest values in the whole time series. For Norway the data prior to 1989 is probably biased because of the size selective drift net fishery that mainly targeted large grilse and smaller MSW salmon.

Grilse weight and grilse catches were positively correlated in rivers in southern Norway and mid Norway, suggesting that cohorts with reduced growth suffered reduced survival. However, in rivers in the northern part of Norway a similar pattern was not observed. Furthermore, the mean weight of grilse in the River Drammen was positively correlated to survival estimates from hatchery smolts released in the same river.

The Working Group also received information from Sweden that the grilse in 2006 were also small and lean, with a mean weight in the sport fishery $17 \%$ less than that in 2005, although MSW salmon were of normal size. Quite a few of the fish caught by anglers in Sweden were reported to be extremely thin and this raised concerns among fishermen about the future. Together with evidence of significantly smaller grilse from parts of UK (England \& Wales), and ad hoc reports from Ireland, it was apparent that reduced grilse size in 2006 was a phenomenon, which affected more southerly areas of Europe.

### 2.6 Tracking and tagging studies

### 2.6.1 Acoustic tracking of migrating Atlantic salmon kelts from the LaHave River, Nova Scotia, Canada

The Working Group reviewed the results of an acoustic tagging experiment in the LaHave River. Salmon kelts were captured in early April by seining, angling, and at a downstream assessment facility 25 km above tide head. Thirty kelts were implanted with acoustic tags, including 5 tags that transmit depth data. A total of 26 continuous recording acoustic receivers were placed in the river 15 km above head of tide to 24 km below tide at the outer limits of the estuary to monitor the passage of tagged fish from April to October (Figure 2.6.1.1). The outward migration of 30 kelts and subsequent return of one consecutive spawning salmon was successfully documented using this method. All kelts left the estuary by the middle of May.

The mortality rate of kelts to migration past the outer array was $10 \%$. Location and duration of residency was recorded and environmental variables were compared to behaviour.

The results indicated that capture by angling was the most successful method and that kelts tolerated handling and surgery well. No mortalities due to capture, holding or surgery occurred. The data on migration rate, diving behaviour and high survival rate were new and important information for this stock, which is experiencing increased mortality to repeat spawning. Only one salmon, a post-spawned 2SW female salmon returned to the estuary after 79 days, spent four days in the estuary and after entering the river reached the assessment facility in one day. This consecutive repeat spawning salmon had increased its weight by $50 \%$. Based on past external (Carlin) tagging experiments the remaining 26 salmon that successfully migrated past the outer array are expected to reach the Labrador Sea within three months and possibly farther north within five months similar to that expected for smolts. If the mortality rate that was measured for salmon exiting the estuary continued for the expected 14 month migration about five salmon could be expected to return in July 2007. However, based on recent observations of the proportions of repeat spawning salmon, fewer salmon may be expected.

The Working Group noted that based on the low mortality rate of kelts migrating past the outer arrays, the expected ocean migration and the large size of kelts, tagging experiments utilizing this stage of salmon, particularly with newly evolving advanced technology tags, could provide critical insights into the migration, behaviour and possibly survival rates to northern geographic areas.

### 2.6.2 Monitoring smolt migration in the River Rhine, Germany

The downstream migration of Atlantic salmon smolts was monitored in the River Rhine in 2006 and 2007 using the NEDAP Trail system (Breukelaar et al., 1998). Overall, 88 tagged fish were released into two tributaries of the River Rhine about 350 km from the sea. The smolts (hatchery $2^{+}$, weight > 150 g ) were tagged with a transponder (length 3.5 cm , weight 11.5 g ) by implantation into the body cavity, and allowed to recover for a period of several days in the hatchery before release to the river. The tagged fish were detected by fixed antenna arrays when leaving the tributary and during their migration through the Rhine delta to the sea. The NEDAP trail system is based on inductive coupling between an antenna loop on the river bottom and a ferrite rod antenna within the transponders. When the fish passes each detection station the unique ID-number of the transponder is recorded.

To April 2007, 64 fish have been detected leaving the tributary of release (5 in 2006 and 59 in 2007, respectively) and 24 ( 1 in 2006 and 23 in 2007, respectively) have been recorded reaching the sea after passing through the Rhine delta. The study aims to investigate the success of downstream migration and the migration routes in relation to the obstructions within the partly dammed Rhine delta, and particularly the Haringvliet sluices. The study will be repeated after re-opening of the Haringvliet dam. This is scheduled to occur by the end of 2008, aimed specifically at improving conditions for migratory fish species during their passage from freshwater to the sea and vice versa.

### 2.6.3 Data Storage Tags and tagging studies in Iceland

Hatchery reared smolts with implanted data storage tags (DST) were released in 2005 and 2006 in an Icelandic river. The first returns (5 salmon) were obtained in 2006. The DST tags recorded temperature and depth for the whole ocean cycle of these salmon. The salmon stayed in the surface layers throughout most of their ocean stay and all showed similar temperature profiles. The research provides new information on the conditions salmon experience at sea. Further analyses of these data as well as tags still to be recovered will provide a considerable input to the understanding of the behaviour of salmon at sea.

### 2.7 Compilation of tag releases and fin clip data by ICES member countries in 2006

Data on releases of tagged, fin-clipped and otherwise marked salmon in 2006 were provided to the Working Group and are compiled as a separate report (ICES, 2007b). In summary (Table 2.7.1), about 3.96 million salmon were marked in 2006, a decrease from the 5.64 million fish marked in 2005. The adipose clip was the most commonly used primary mark ( 3.02 million), with microtags ( 0.84 million) the next most common primary mark. Most marks were applied to hatchery-origin juveniles ( 3.85 million), while 94713 wild juveniles and 21013 adults were also marked. The use of PIT (Passive Integrated Transponder) as well as other implanted tags for marking Atlantic salmon has increased in the later years and are now listed in a separate column in Table 2.7.1. In 2006, 6305 PIT tagged salmon, Data Storage Tags (DSTs), radio and/or sonic transmitting tags (pingers) were also used.

From 2003, the Working Group has recorded information on marks being applied to farmed salmon. These may help trace the origin of farmed salmon captured in the wild in the case of escape events. At this time, two jurisdictions (USA-Maine, and Iceland) require that some or all of the sea-cage farmed fish reared in their area be marked. In Maine, some firms have opted for a genetic "marking" procedure. The broodstock of these firms has been screened with molecular genetic techniques, which makes it feasible to trace an escaped farmed salmon back to its hatchery of origin through analysis of its DNA. One company has applied ventral fin clip, but has not reported numbers for reasons of commercial confidentiality. In Iceland, coded wire tags are being applied to about $10 \%$ of sea-cage farm production. The Icelandic data are included in ICES (2007b), but the USA numbers are not included.

### 2.8 Summary of the Workshop on the Development and Use of Historical Salmon Tagging Information from Oceanic Areas (WKDUHSTI)

Results from the Workshop on the Development and Use of Historical Salmon Tagging Information from Oceanic Areas (WKDUHSTI) were presented to the Working Group. Data were provided from a number of countries, including tag recoveries in oceanic areas from smolt tagging in home waters, and recoveries in oceanic areas as well as in home waters of salmon tagged at sea. A framework for analyses of data was developed, and a standard format for recording tag recoveries was agreed. Using GIS as a tool, examples of geographical distribution of recaptured salmon originating from different areas were provided, demonstrating the potential for the use of this tool. A number of hypotheses relating to oceanic migration and distribution, which could be tested using tagging and recapture material, were discussed and developed. Tag recovery information could be complemented by genetic analyses of time series of available scale or tissue samples in relation to salmon life-history information derived from scale pattern analyses of freshwater and marine growth characteristics.

The Workshop concluded that there is great potential to analyse standardised datasets, but it remains to develop detailed statistical methods and models to analyse the material and test appropriate hypotheses. There is still a large amount of material available, but this has to be standardised and converted to the same format, as agreed in WKDUHSTI. An EXCEL file with the appropriate form was developed and should be made available to tagging agencies in the different countries. The workshop recommended that this framework be used for future contributions to the tag recovery data set. Each tagging agency should utilize the framework to prepare data for analysis at the next Workshop. It was recommended that agencies coordinate their efforts to ensure that datasets are not duplicated.

It was recommended that a similar Workshop be held sometime in 2007 or 2008 to complete compilation of available data and analyses of the resulting distributions of salmon at sea. In this regard, the Workshop considered that the integration of historical tagging data for NEAC
and NAC provides a significant opportunity to advance the state of knowledge of the marine distribution and migration of salmon. It was recommended that this Workshop should include oceanographers to assist with describing salmon distributions and relating them to the ocean environment.

Table 2.1.1.1. Nominal catch of salmon by country (in tonnes round fresh weight), 1960-2006. (2006 figures include provisional data).

Key:

1. Includes estimates of some local sales, and, prior to 1984, by-catch.

Before 1966 , sea trout and sea charr included ( $5 \%$ of total).
3. Figures from 1991 to 2000 do not include catches taken in the recently developed recreational (rod) fishery.
4. Improved reporting of rod catches in 1994 and data derived from carcase tagging and log books from 2002
5. Catch on River Foyle allocated $50 \%$ Ireland and $50 \% \mathrm{~N}$. Ireland
6. Angling catch (derived from carcase tagging and log books) first included in 2002.
7. Data for France include some unreported catches
8. Weights estimated from mean weight of fish caught in Asturias ( $80-90 \%$ of Spanish catch)
9. Between $1991 \& 1999$, there was only a research fishery at Faroes. In $1997 \& 1999$ no fishery took place;
the commercial fishery resumed in 2000 , but has not operated since 2001.
10. Includes catches made in the West Greenland area by Norway, Faroes,

Sweden and Denmark in 1965-1975
11. Includes catches in Norwegian Sea by vessels from Denmark, Sweden, Germany, Norway and Finland
12. Estimates refer to season ending in given year

Table 2．1．1．2．Nominal catch of salmon in homewaters by country（in tonnes round fresh weight），1960－2006．（2006 figures include provisional data）． $\mathbf{S}=$ Salmon（2SW or MSW fish）．$G=G r i l s e(1 S W$ fish）． $\mathbf{S m}=$ small． $\mathbf{L g}=$ large；for definitions，see Section 4．1．$T=S+G$ or $\mathbf{L g}+\mathbf{S m}$ ．

Notes: Data for 2006 are provisional for many countries.
Where production figures were not available for 2006, values as in 2005 were assumed.
West Coast USA = Washington State
West Coast Canada = British Columbia
Australia = Tasmania
Source of production figures for non-Atlantic areas: miscellaneous fishing publications \& Government reports (including Kjønhaug, 2007). Other' includes South Korea \& China.

Table 2.4.2.1. Returns ( $25^{\text {th }}$ percentile) of 2 SW salmon to six geographic areas of NAC and the southern NEAC MSW PFA. For NAC geographic areas, the $25^{\text {th }}$ percentile is calculated from the minimum and maximum ranges for each area, except for US where the values are point estimates.

Figure 2.1.1.3. Nominal catch taken in coastal, estuarine and riverine fisheries for the NAC area, and for the NEAC northern and southern areas. Note that time series and $y$-axes vary.

Figure 2.1.3.1. Nominal North Atlantic salmon catch, unreported catch and percentage unreported (expressed as \% of total catch - nominal + unreported) in NASCO areas, 1987-2006.

Figure 2.2.1.1. World-wide production of farmed Atlantic salmon, 1980-2006.

Figure 2.2.2.1. Production of ranched Atlantic salmon (tonnes round fresh weight) as harvested at ranching facilities in the North Atlantic, 1980-2006.

Figure 2.3.1.1. An equilibrium model linking habitat quality and quantity to fish population dynamics. A Beverton-Holt model is used to model the density-dependent relationship for survival from eggs to smolt (a). The slope at the origin of this model, which is the maximum number of smolts produced per egg in the absence of density dependent effects, changes as habitat quality changes, whereas changes in the amount of habitat change the carrying capacity. The number of eggs produced per smolt (b) throughout its life, changes with smolt-to-adult survival, fecundity, age-at-maturity or the number of times a fish spawns throughout its life. The population equilibrium occurs at the population size where the production of smolts by eggs is in balance with the production of eggs by smolts throughout their lives, and is the size at which the population will stabilize if all rates and the carrying capacity remain unchanged (c). The population equilibrium changes as the vital rates change and can be used to assess how a population is expected to change in response to human activities.

Figure 2.3.1.2. Dynamics of the LaHave River (above Morgan Falls) salmon population. The points are the observed egg depositions and smolt production for the 1994 to 2001 cohort years. The solid line is a Beverton Holt model obtained by fitting these data to the population spawning above Morgan Falls. The dashed lines show the replacement lines calculated using the minimum, average and maximum smolt to adult return rates observed for this population between 1996 and 2004. Shading indicates the status relative to the conservation egg requirement: dark shading is above the requirement, the medium shading is between $50 \%$ and $100 \%$ of the egg requirement and the light shading is below the requirement.

Figure 2.3.1.3. Equilibrium analysis of the recovery potential of salmon in West River (Sheet Harbour, NS). The upper left panel shows the present dynamic in which populations aren't viable as a result of low marine survival and reduced freshwater production due to acidification. The slopes of replacement lines are calculated using the mean, minimum and maximum return rates for LaHave River salmon for the 1996 to 2004 return rates. The upper right panel shows the expected change in freshwater production if the acidification problem was addressed in the entire river. The lower left panel shows the dynamics if freshwater production remains unchanged and at-sea survival rates are the mean and maximum returns rates from the LaHave River, together with a hypothesized return rate increase to $6 \%$ for 1 SW and $2 \%$ for 2SW salmon. The lower right panel shows a combined increased freshwater production and increased marine survival scenario in which the conservation egg requirement is reached. Shading indicates the status relative to the conservation egg requirement: dark shading is above the requirement, the medium shading is between $\mathbf{5 0 \%}$ and $\mathbf{1 0 0 \%}$ the egg requirement and the light shading is below the requirement.

Number per $100 \mathrm{~m}^{2}$

Figure 2.3.6.1. Observed (points) and predicted (lines) densities of Atlantic salmon obtained by fitting three models to the data. The data are the observed abundance or density within a cohort by age. The solid line is a one-parameter model that shows the fit obtained based on the assumption that survival is density independent. The dashed and dotted lines show the fits obtained from two-parameter Beverton-Holt and Ricker models respectively. Note: egg deposition time series not available for the Stewiacke River.

Carrying Capacity ( $\mathrm{N} / 100 \mathrm{~m}^{2}$ )

Figure 2.3.6.2. A meta-analytic summary of the habitat carrying capacity for age-1 parr for nine salmon populations. The light grey shaded regions are individual fits that depict the profile likelihood for carrying capacity, truncated to show the $95 \%$ confidence interval. The height of the profile is used to gauge the relative plausibility of different values (greater height is more plausible). The black dot is the maximum likelihood estimate for each parameter. The dark grey shaded regions show summaries of the mixed model fits. The "mixed model mean" represents the estimated mean of the logarithm of carrying capacity for these rivers with a $\mathbf{9 5 \%}$ confidence interval. The "mixed model estimated random effects distribution" is the normal distribution for the logarithm of carrying capacity based on its mean and variance and shows the distribution expected for the region.

Figure 2.3.7.1 Gill $^{\left(N a^{+}\right.}$, $\mathrm{K}^{+}$-ATPase activity for river resident parr (sampled in November and January), autumn migrants (sampled in October and November), estuarine residents (sampled in December and February) and smolts (sampled in April) on the River Frome in 2005/06 (* denotes significantly elevated levels).

Figure 2.4.2.1. Geographic position of all indicator rivers where data sets originated from and were considered for inclusion into the Framework of Indicators from North American Commission area. Black bullets identify rivers where the data were incorporated in the framework and grey bullets identify rivers for which the indicator variables were not used.

Figure 2.4.2.2. Comparative performance of the retained indicators $(\mathbf{N}=32)$ at identifying a true low (i.e. management objective will not be met) and a true high (i.e. management objective will be met) for the West Greenland multi-year catch advice framework.

Figure 2.4.3.1. Framework of indicators spreadsheet for the West Greenland fishery. For illustrative purposes, the average of the most recent ten years of returns or return rates for the 32 retained indicators is entered in the cells corresponding to the annual indicator variable values.

Figure 2.4.3.2. Suggested timeline for employment of the Framework of Indicators (FWI). In Year i, ICES provides multi-year catch advice (MYCA) and an updated FWI which re-evaluates the updated datasets and is summarized in an Excel worksheet. In January of Year $i+1$ the FWI is applied and two options are available depending on the results. If no significant change is detected, no re-assessment is necessary and the cycle continues to Year $i+2$. If no significant change is detected in Year $i+2$, the cycle continues to Year $i+3$. If a significant change is detected in any year, then reassessment is recommended. In that case, ICES would provide an updated FWI the following May. ICES would also provide an updated FWI if year equals 4.

Figure 2.6.1.1. Location and map of the LaHave River, and estuary, Nova Scotia, Canada, indicating the capture site of Atlantic salmon kelts at New Germany Lake and release site at Morgan Falls, and the head of tide at the town of Bridgewater (stars), also shown are the location of acoustic receivers 1-26 (black circles).

## 3 North-East Atlantic Commission

### 3.1 Status of stocks/exploitation

The status of stocks is considered with respect to the following guidance from ICES.
The interpretation of conservation limits (CLs) has been defined by ICES as the level of stock that will achieve long term average maximum sustainable yield (MSY). NASCO has adopted this definition of CLs (NASCO, 1998). The CL is a limit reference point; having populations fall below these limits should be avoided with high probability. However, management targets have not yet been adopted for Atlantic salmon stocks. Therefore homewater stocks in the NEAC area have been interpreted to be at full reproductive capacity only if the lower bound of the $95 \%$ confidence interval of the most recent spawner estimate is above the CL. In a similar manner, the status of stocks prior to the commencement of distant water fisheries has been interpreted to be at full reproductive capacity only if the lower bound of the $95 \%$ confidence interval of the most recent pre fishery abundance (PFA) estimate is above the Spawner Escapement Reserve (SER).

National outputs of the NEAC PFA model are combined in the following groups to provide NASCO with catch advice or alternative management advice for the distant water fisheries at West Greenland and Faroes.

| Southern European countries: | Northern European countries: |
| :--- | :--- |
| Ireland | Finland |
| France | Norway |
| UK (England \& Wales) | Russia |
| UK (Northern Ireland) | Sweden |
| UK (Scotland) | Iceland (north/east regions) |
| Iceland (south/west regions) $^{1}$ |  |

Justification for these groupings is provided in Section 3.5.
The status of these stock complexes prior to the commencement of distant water fisheries with respect to the SER requirements is:

- Northern European 1SW stocks are considered to be at full reproductive capacity.
- Northern European MSW stocks are considered to be at full reproductive capacity.
- Southern European 1SW stocks are considered to be at risk of suffering reduced reproductive capacity.
- Southern European MSW stocks are considered to be at risk of suffering reduced reproductive capacity.

The status of stocks is shown in Figure 3.1.1 and is elaborated upon in Section 3.4.
Estimated exploitation rates have generally been decreasing over the time period for both 1SW and MSW stocks in Northern and Southern NEAC areas (Figure 3.8.15.1 and Figure 3.8.15.2). Exploitation on Northern 1SW stocks is higher than on Southern 1SW and considerably higher for MSW stocks. There has been a slight increase in exploitation on 1SW and 2SW northern stocks since 2002. However, the current estimates for both stock complexes are amongst the lowest in the time series.

### 3.2 Management objectives

Management objectives are outlined in Section 1.4.

### 3.3 Reference points

Section 1.5 describes the derivation of reference points for these stocks and stock complexes.

### 3.3.1 Description of the national conservation limits model

River-specific conservation limits have been developed for salmon stocks in some countries in the NEAC area. An interim approach has therefore been developed for estimating national conservation limits for countries that cannot provide one based upon river-specific estimates. The approach is based on establishing pseudo-stock-recruitment relationships for national salmon stocks in the North East Atlantic Commission (NEAC) area (Potter et al., 1998).

As described in 2002 (ICES, 2002), the model provides a means for relating estimates of the numbers of spawners and recruits derived from the PFA model. This is achieved by converting the numbers of 1SW and MSW spawners into numbers of eggs deposited, using the proportion of female fish in each age class and the average number of eggs produced per female. The egg deposition in year ' $n$ ' is assumed to contribute to the recruitment in years " $n+3$ " to " $n+8$ " in proportion to the numbers of smolts produced of ages 1 to 6 years. These proportions are then used to estimate the 'lagged egg deposition' contributing to the recruitment of maturing and non-maturing 1SW fish in the appropriate years. The plots of lagged eggs (stock) against the 1SW adults in the sea (recruits) have been presented as 'pseudo-stock-recruitment' relationships for each homewater country except for countries with river specific CLs.

ICES currently defines the conservation limit for salmon as the stock size that will result in the maximum sustainable yield (MSY) in the long term. However, it is not straightforward to estimate this point on the national stock-recruitment relationships because the replacement line (i.e. the line on which 'stock' equals 'recruits') is not known for the pseudo-stock-recruitment relationships established by the national model because the stock is expressed as eggs, while the recruits are expressed as adult salmon. In 2001 the Working Group adopted a method for setting biological reference points from the national pseudo-stock-recruitment datasets (ICES, 2001). This model assumes that there is a critical spawning stock level below which recruitment decreases linearly towards zero, and above which recruitment is constant. The position of the critical stock level is determined by searching for the value that minimises the residual sum of squares. This point is a proxy for $S_{\text {lim }}$ and is therefore defined as the conservation limit for salmon stocks. This approach was again applied to the 2006 national stock-recruitment relationship assessment for countries where no river-specific conservation limits have been determined.

### 3.3.2 National conservation limits

The national CL model has been run for all countries (see Section 3.8.12) and the conservation limits are used for countries where no river specific conservation limits have been developed. Where river-specific estimates have been derived (ie. France, Ireland and UK (England \& Wales)) they are used to provide national estimates (Table 3.3.2.1).

The Working Group has previously noted that outputs from the national model are only designed to provide a provisional guide to the status of stocks in the NEAC area. The estimated national conservation limits have been summed for Northern and Southern Europe and are given in Figure 3.1.1 for comparison with the estimated spawning escapement. The conservation limits have been calculated as:

- Northern NEAC 1SW spawners - 271111
- Northern NEAC MSW spawners - 140230
- $\quad$ Southern NEAC 1SW spawners - 624221
- Southern NEAC MSW spawners - 269237

The conservation limits have also been used to estimate the SERs (i.e. the CL increased to take account of natural mortality between the recruitment date ( $1^{\text {st }} \mathrm{Jan}$ ) and return to home waters) for maturing and non-maturing 1SW salmon from the Northern and Southern Europe stock complexes. The SERs are shown in Figure 3.1.1 and Table 3.3.2.1. The Working Group also considers the current SER levels may be less appropriate for evaluating the historic status of stocks (e.g. pre-1985), that in many cases have been estimated with less precision.

### 3.3.3 Progress with setting river-specific conservation limits

Most NEAC countries have not developed river-specific conservation limits (CLs). In 2006, progress with setting river-specific CLs and associated compliance assessment was reported for Iceland, UK (Scotland) and Norway.

In Iceland work is progressing on several rivers to derive river specific CLs. Several datasets and techniques (catch data, counter data, habitat mapping, wetted area and juvenile surveys) are being used to estimate salmon production, run size and spawning escapement. To date work has indicated highly variable spawning reference levels. The next stage of the work will explore if and how CLs can be transported to recipient rivers.

In UK (Scotland) work has begun to develop procedures for setting river specific CLs. GIS applications, in conjunction with field based observation and a literature review of salmon distribution, have been used to develop a map based useable wetted area model for salmon which can be used to transport CLs among catchments. A CL has been derived for the North Esk and this has been transported to several recipient rivers. Methods to determine spawning escapement values in these rivers are now being investigated.

In Norway work is in progress to set conservation limits in 80 rivers. This work is based on stock recruitment relationships in nine rivers, and further transportation to data poor rivers based on similarities in productivity and stock age structure. Productivity is mostly based on catch statistics, and scale samples used to access the river- and sea age structure in a sub set of the populations. To derive the conservation limits, wetted area has been computed for the rivers based on digital maps and knowledge of how far salmon can migrate in the rivers. This work is planned to be reported to the Directorate for Nature Management during the summer of 2007.

### 3.4 Management Advice

ICES uses the catch advice presented in this section to determine whether or not stock complexes are at full reproductive capacity. The Working Group is unable to provide quantitative catch options for most stock complexes at this stage. To do so requires predictive estimates of PFA which have not yet been developed for all stock complexes. Initial attempts to develop forecast models for the Northern maturing 1SW, the Northern non-maturing 1SW and the Southern maturing 1SW stock complexes did not have sufficient predictive power to prove useful. The Working Group recommends further attempts to develop predictive models for all NEAC stock complexes. A quantitative prediction of PFA for Southern European MSW stocks is again provided. The Working Group considers that the following qualitative catch advice is appropriate based upon the PFA data and estimated SERs shown in Figure 3.1.1. In the evaluation of the status of stocks, PFA or recruitment values should be assessed against the SER values while the spawner numbers should be compared with the CLs.

Based on recent work on resolving the most appropriate stock groupings for management advice for the distant water fisheries (ICES, 2002, 2005) the Working Group agreed that:

- Advice for the Faroes fishery should be based upon all NEAC stocks.
- Advice for the West Greenland fishery should be based upon southern European non-maturing 1 SW salmon stocks.

The interpretations presented below are based on the results presented in Figure 3.1.1.

### 3.4.1 Northern European maturing 1SW stocks

- The lower bound of the PFA estimate has been above the SER throughout the series indicating an exploitable surplus and this stock is currently at full reproductive capacity prior to the commencement of distant water fisheries.
- The lower bound of the spawner estimate has fluctuated around the CL throughout most of the time series. In 2006, the lower bound of the spawner estimate was above the CL and this stock complex is currently at full reproductive capacity after homewater fisheries have taken place.
- In the absence of specific management objectives for this stock complex the precautionary approach is to fish only on maturing 1SW salmon from rivers where stocks have been shown to be at full reproductive capacity.

### 3.4.2 Northern European non-maturing 1 SW stocks

- The lower bound of the PFA estimate has been above the SER throughout the series indicating an exploitable surplus and this stock is currently at full reproductive capacity prior to the commencement of distant water fisheries.
- The lower bound of the spawner estimate has fluctuated around the CL throughout most of the time series. In 2006, the lower bound of the spawner estimate was above the CL and this stock complex is currently at full reproductive capacity after homewater fisheries have taken place.
- In the absence of specific management objectives for this stock complex the precautionary approach is to fish only on non-maturing 1SW salmon from rivers where stocks have been shown to be at full reproductive capacity.

### 3.4.3 Southern European maturing 1 SW stocks

- The lower bound of the PFA estimate fell below the SER for the first time in the series in 2006. This stock complex is currently at risk of suffering reduced reproductive capacity prior to the commencement of distant water fisheries.
- The mid-point and the lower bound of the spawner estimate has fluctuated around the CL throughout most of the time series. In 2006, both the mid-point and the upper bound of the spawner estimate were below the CL and this stock complex is suffering reduced reproductive capacity after homewater fisheries have taken place.
- In the absence of specific management objectives for this stock complex the precautionary approach is to fish only on maturing 1SW salmon from rivers where stocks have been shown to be at full reproductive capacity. The Working Group considers that reductions in exploitation are required for as many stocks as possible, to increase the probability of the complex meeting conservation limits. Furthermore, due to the different status of individual stocks within the stock complex, mixed stock fisheries present particular threats to stock status.

### 3.4.4 Southern European non-maturing 1SW stocks

- The lower bound of the PFA estimate has been above the SER throughout most of the series but is currently below. Thus this stock complex is currently at risk of suffering reduced reproductive capacity prior to the commencement of distant water fisheries.
- The mid-point and the lower bound of spawner estimate have been close to or below the CL since 1997. This stock complex is suffering reduced reproductive capacity after homewater fisheries have taken place.
- The quantitative forecast of PFA for 2007 indicates that this stock complex is expected to continue to decline from the previous year. In the absence of any fisheries on this stock complex there is a less than 64\% probability that the CL will be achieved in 2008 (see Section 5.4). The PFA forecast for 2007-2010 predicts values below the SER and therefore there should be no fishing on this complex at West Geenland or Faroes. In the absence of specific management objectives for this stock complex, with the exception of the West Greenland fishery, the precautionary approach is to fish only on non-maturing 1SW salmon from rivers where stocks have been shown to be at full reproductive capacity. The Working Group considers that reductions in exploitation are required for as many stocks as possible, to increase the probability of the complex meeting conservation limits. Furthermore, due to the different status of individual stocks within the stock complex, mixed stock fisheries present particular threats to stock status.

### 3.5 Relevant factors to be considered in management

The Working Group reiterated its concerns about harvesting salmon in mixed stock fisheries, particularly for fisheries exploiting individual river stocks and sub-river populations that are at risk or suffering reduced reproductive capacity. Annual adjustments in quotas or effort regulations based on changes in the status of the stock complexes are unlikely to provide adequate protection to the individual river stocks that are most heavily exploited by the fishery or are in the weakest condition.

For all stock complexes, the Working Group considers that management of single stock fisheries should be based upon local assessments of the status of stocks. Conservation would be best achieved by fisheries in estuaries and rivers targeting stocks that have been shown to be above escapement requirements.

It should be noted that the inclusion of farmed fish in the Norwegian data would result in the stock status being overestimated. Since very few of these salmon have been caught outside homewater fisheries in Europe, even when fisheries were operating in the Norwegian Sea, management of maturing 1SW salmon should be based upon local assessments of the status of river or sub-river stocks.

The Working Group also emphasised that the national stock conservation limits discussed above are not appropriate for the management of homewater fisheries, particularly where these exploit separate river stocks. This is because of the relative imprecision of the national conservation limits and because they will not take account of differences in the status of different river stocks or sub-river populations. Nevertheless, the Working Group agreed that the combined conservation limits for the main stock groups (national stocks) exploited by the distant water fisheries could be used to provide general management advice to the distant water fisheries.

### 3.5.1 Grouping of national stocks

National outputs of the NEAC PFA model are combined into southern European and northern European groups (see Section 3.1) to provide NASCO with catch advice or alternative management advice for the distant water fisheries at West Greenland and Faroes.

The groups were deemed appropriate by the Working Group as they fulfilled an agreed set of criteria for defining stock groups for the provision of management advice that were considered in detail at the 2002 meeting (ICES, 2002) and re-evaluated at the 2005 meeting (ICES, 2005). Consideration of the level of exploitation of national stocks at both the distant water fisheries resulted in the proposal that advice for the Faroes fishery (both 1SW and MSW) should be based upon all NEAC area stocks, but that advice for the West Greenland fishery should be based upon Southern European MSW salmon stocks only.

### 3.6 Pre-Fishery Abundance Forecast for 2006-2010 for the Southern NEAC stock complex

The Working Group has previously considered the development of a model to forecast the PFA of non-maturing (potential MSW) salmon from the Southern European stock group (ICES, 2002, 2003). The model has been used to provide such forecasts (ICES, 2006) which are used as one of the inputs to the risk analysis of the catch options for the Greenland fishery (see Section 5). The full model takes the form
$P F A=$ Spawners $^{\lambda} \times e^{\beta_{0}+\beta_{1} \text { Habitat }+\beta_{2} \log (\text { PFAm })+\beta_{3} \text { Year }+ \text { noise }}$
where Spawners are expressed as lagged egg numbers, $P F A m$ refers to pre-fishery abundance of maturing 1SW salmon (derived from NEAC PFA model - see Section 3.8.9) and the habitat term is the same as that previously used in the North American model (ICES, 2003). As updated data for the Habitat parameter have not been available to the Working Group since 2003, however, the term was not included in the parameter selection process in 2007.

Provision of 3-year management advice for the Faroese fishery requires that PFA forecasts be extended to 2010, one year further than has previously been made available. The number of years for which forecasts may be provided is limited by the Spawner (lagged egg) parameter within the model. The time series for this parameter extends only as far as those lagged eggs assigned to 1-year old smolts from the most recent available spawning year, currently lagged eggs for 2009 derived from 2006 spawner estimates. To allow PFA forecasts for 2010, lagged egg production assigned to 1-year old smolts for 2010 for each home water country was estimated by taking the average of the previous 5 years.

In previous years (ICES, 2004), parameter selection was achieved by adding variables (Spawners, PFAm and Year) until the addition of others did not result in an increase in the explanatory power of the model. The model was fitted to data from 1978 to 2005 (Table 3.6.1.1) and, as in previous years, the parameters selected were Spawners and Year. The final model took the form
$\log ($ PFA/Spawners $)=-1.30 \log ($ Spawners $)+118.5-0.050$ Year
which is equivalent to:
PFA $=$ Spawners ${ }^{-0.30} \mathrm{x}^{118.5-0.050 \text { Year }}$.
The PFA forecasts (Figure 3.6.1.1, Table 3.6.1.2) indicate that for 2006 and 2007, the Southern NEAC stock complex is at risk of suffering reduced reproductive capacity while from 2008 to 2010, the stock complex will be suffering reduced reproductive capacity. No forecasts are available for other stock components or complexes in the NEAC area.

### 3.7 Comparison with previous assessment

### 3.7.1 National PFA model and national conservation limit model

Provisional catch data for 2005 were updated where appropriate. In addition, changes were made to the input data from Iceland. Exploitation rates were reduced in recent years to take into account the increasing practice of catch and release in the rod fishery. Changes were also made to non-reporting rates to better reflect current knowledge.

### 3.7.2 PFA forecast model

The midpoints of updated forecasts of the southern NEAC MSW PFA for the years 2006 to 2008 were 484000 , 455000 and 434000 respectively. All were between $1 \%$ and $2 \%$ lower than the forecasts ( 489000,461000 and 440000 ) provided last year.

### 3.8 NASCO has requested ICES to describe the key events of the 2006 fisheries and the status of the stocks

### 3.8.1 Fishing at Faroes in 2005/2006

No fishery for salmon has been carried out since 2000. No buyout arrangement has been in force since 1999.

### 3.8.2 Significant events in NEAC homewater fisheries in 2006

## Ireland

Since 2002, salmon fishing effort in Ireland has been affected by the imposition of a commercial fishery TAC. An initial commercial TAC of 219619 fish was imposed for the 2002 season, followed by reduced TACs of 182000 fish for 2003 and 162000 fish in 2004 and 139900 in 2005. A TAC of 91000 salmon was applied for the 2006 fishery based on the recommendations of the National Salmon Commission.

Mandatory catch and release operated from the 1st of September in 8 of the 17 total fishery districts which were assessed as being below their conservation limits.

## UK (England \& Wales)

Progress to phase out various net fisheries continued in 2006. A previously agreed phase out of both trammel and seine net fisheries on the River Dee (North Wales) was accelerated with compensation payments agreed with four fishermen. Reductions in effort were also introduced for two rivers in south west England, the Dart and Teign, where the number of seine net licences was reduced to 3 on each river from 13 and 6, respectively. These reductions were also facilitated by compensation payments to the netsmen.

### 3.8.3 Gear and effort

In 2006 no significant changes in the type of gear used for salmon fishing were reported in the NEAC area.

The number of gear units licensed or authorised in several of the NEAC area countries provides a partial measure of effort (Table 3.8.3.1), but does not take into account other restrictions, for example, closed seasons. In addition, there is no indication from these data of the actual number of licences utilised or the time each licencee fished.

Trends in effort are shown in Figures 3.8.3.1 and 3.8.3.2 for the Northern and Southern NEAC countries respectively. In the Northern NEAC area, drift net effort in Norway accounted for the majority of the effort expended in the early part of the time-series. However, this fishery closed in 1989, reducing the overall effort substantially. The two remaining methods, bagnets and bendnets, show contrasting patterns of effort until the early 1990s when both show downward trends until the end of the time-series. In the Archangel region of Russia, the effort in the river commercial fishery shows a decline while the effort in the coastal fishery shows no trend for the time series reported. In the Southern NEAC countries, net effort data show a downward trend of various degrees for UK (England \& Wales), UK (Northern Ireland), Ireland, France and UK (Scotland).

Rod effort, where available, show both upward and downward trends for the period reported. In the Northern NEAC area the catch and release rod fishery in the Kola Peninsula in Russia has increased from 1711 fishing days in 1991 to 13604 in 2006. In Finland the number of fishing days has shown an increase throughout the time period. In the Southern NEAC area rod fishing effort decreased in 2006 in UK (England \& Wales). In Ireland there has been an apparent increase in rod fishing effort due to the introduction of one day licences in the early 1990s and has remained stable over the past decade. In France the effort has been fairly stable over last 10 years.

### 3.8.4 Catches

NEAC area catches are presented in Table 3.8.4.1. The provisional declared catch in the NEAC area in 2006 was 1846 tonnes, slightly lower that in 2005 (1995 t). The NEAC catch represents $92 \%$ of the total North Atlantic nominal catch in 2006. The catch in the NEAC Southern area ( 618 t ) fell by $23 \%$ on 2005 and was the lowest in the time series. The catch in the NEAC Northern area ( 1228 t ) was $3 \%$ higher than the catch in 2005, but was $12 \%$ below the recent 5-year mean and among the lowest in the time series.

Figure 3.8.4.1 shows the trends in nominal catches of salmon in the Southern and Northern NEAC areas from 1971 until 2006. The catch in the Southern area has declined over the period from about 4500 t in 1972-75 to below 1500 t since 1986, and is now well below 1000 t. The catch declined particularly sharply in 1976 and again in 1989-91. The catch in the Northern area also shows an overall decline over the time series, but this is less steep than for the Southern area. The catch in the Northern area varied between 1850 and 2700 t from 1971 to 1986 , fell to a low of 962 t in 1997, and then increased to over 1500 t in 2001. The catch has shown a downward trend again since this time. Thus, the catch in the Southern area, which comprised around two-thirds of the NEAC total in the early 1970s, has been lower than that in the Northern area since 1999.

### 3.8.5 Catch per unit effort (CPUE)

CPUE is a measure that can be influenced by various factors, and it is assumed that the CPUE of net fisheries is a more stable indicator of the general status of salmon stocks than rod CPUE; the latter may be more affected by varying local factors, e.g. weather conditions, management measures and angler experience. Both may also be affected by many measures taken to reduce fishing effort, for example, changes in regulations affecting gear. If large changes occur for one or more factors a common pattern may not be evident over larger areas. It is, however, expected that for a relatively stable effort, CPUE can reflect changes in the status of stocks and stock size.

The CPUE data are presented in Tables 3.8.5.1-3.8.5.5. The CPUE for rod fisheries have been collected by relating the catch to rod days or angler season, and that of net fisheries was calculated as catch per licence-day, trap month or crew month

In the Southern NEAC area, CPUE show a general decrease in UK (Scotland) and UK (England \& Wales) net fisheries. CPUE for the net fishery showed mostly lower figures compared to 2005 and the previous 5 -year averages (Table 3.8.5.3). In UK (Northern Ireland), the river Bush rod fishery CPUE has increased after 2002, which was the lowest level in recent years, and the 2006 figure was higher than that of the previous year and the 5 -year mean (Table 3.8.5.1)

In the Northern NEAC area, there has been an increasing trend in the CPUE figures for Norwegian net fisheries and Russian rod fisheries in Barents Sea rivers. A decreasing trend was noted for rod fisheries in Finland (River Teno) and Russian White Sea rivers. In comparison with the previous year, most CPUE values were up and higher than the previous 5 -year means (Tables 3.8.5.1, 3.8.5.2, and 3.8.5.5)

### 3.8.6 Age composition of catches

The percentage of 1SW salmon in NEAC catches is presented in Table 3.8.6.1 and in Figures 3.8.6.1 (Northern area) and 3.8.6.2 (Southern area). Since 1987, the proportion of 1SW fish has varied between 54 and $72 \%$ in the Northern area and between 49 and $65 \%$ in the Southern area. In the Northern area, there has been greater variability in the proportion of 1SW fish among countries in recent years (since 1994) than prior to this time. The proportion of 1SW fish in the catch decreased in Norway and Iceland and increased in Russia in 2006, for the other countries the proportions were relatively similar to the 2005 levels.

The percentage of 1 SW fish in the Northern area was $60 \%$ in 2006 , a little below the 5 - and 10 -year means. On average, 1SW fish comprise a higher proportion of the catch (around 7585\%) in Iceland and Russia than in the other Northern countries (Figure 3.8.6.1). In the Southern European countries (Figure 3.8.6.2), the overall percentage of 1SW fish in the catch (59\%) was close to the 5 - and 10-year mean (60\%). On average, 1SW fish comprise a higher proportion of the catch (70-80\%) in UK (England \& Wales) than in the other countries of Southern NEAC.

### 3.8.7 Farmed and ranched salmon in catches

The contribution of farmed and ranched salmon to national catches in the NEAC area in 2006 was again generally low ( $<2 \%$ in most countries) and is similar to the values that have been reported in previous reports (eg. ICES, 2006). Thus, the occurrence of such fish is usually ignored in assessments of the status of national stocks (Section 3.8.12). However, in Norway farmed salmon continue to form a large proportion of the catch in coastal ( $33 \%$ in 2006) , fjordic (19\% in 2006) and rod fisheries (7\% in 2006). An assessment of the likely effect of these fish on the output data from the PFA model has been reported previously (ICES, 2001).

### 3.8.8 National origin of catches

In the course of collecting coded wire tagged salmon from Irish tagging programmes, tags are also recovered from salmon that originate from other countries where coded wire tagging takes place. In 2006, 31 tags originating from fish released from five other countries were recovered in Irish fisheries: 15 from UK (Northern Ireland), 9 from UK (England \& Wales), 2 from Spain and 5 from Germany.

Due to the large difference in the number of tagged salmon being released by each country and the consistency of tagging programmes, tag recoveries are expressed as recapture rates per 1,000 fish released (raised to the total fishery and including an estimate of unreported catch) to provide the relative contribution of tagged salmon by each country to the Irish fishery (Table 3.8.8.1). Tag release information is derived from information reported annually to ICES (Reports of the ICES Compilation of Microtags, Finclips and External Tag Releases, 1985 to 2006). For UK (England and Wales) tagged parr have comprised a large proportion of the fish tagged in some years, and these are generally regarded as contributing to returns two years after release, but this is known to vary. Similarly, by combining the indices at a country level important regional differences may be obscured. Noting these caveats, highest average recapture rates for tagged salmon released in areas other than Ireland are UK (N. Ireland), UK (Scotland), Denmark, France, UK (England and Wales), Spain, Germany and Norway respectively.

River-specific models based on the run reconstruction approach were presented for a number of English and Welsh stocks (ICES, 2004); the inclusion of confidence limits on the estimates of exploitation marked a further advance on earlier models, and Table 3.8.8.2 provides updated estimates. Prior to 1997, exploitation rates in the Irish fishery were estimated at about 1\% for stocks from the north east of England, higher (13 to 17\%) for two rivers in Wales, but highest (28\%) for the River Test in southern England. New management measures were introduced in the Irish fishery in 1997 and since 2002 the fishery has been regulated by quotas, which have reduced each year. Exploitation rate estimates since 1997 indicate a reduction in exploitation of English and Welsh stocks, with average values of $0.5 \%$ for the Tyne (data for one year only), 2 to $8 \%$ for Welsh rivers and $12 \%$ for the River Test. While it was not possible to use the modelling approach to estimate exploitation rates for other stocks, the overall pattern of tag recapture rates has been consistent with this regional pattern of exploitation. Recent estimates for the River Tamar in south west England (2003-05 only) indicate a current exploitation rate in Ireland of about 2\% for this stock.

The Working Group recognised that exploitation rates varied considerably from year-to-year and that exploitation rates on particular stocks may still be relatively high in some years and
negligible in others. For stocks below their conservation limit, the Working Group noted that even low levels of exploitation may represent an impediment to stock recovery, particularly for those rivers designated as Special Areas of Conservation (Section 3.9).

### 3.8.9 The NEAC-PFA model

The Working Group has previously developed a model to estimate the pre-fishery abundance (PFA) of salmon from countries in the NEAC area. PFA in the NEAC area is defined as the number of 1 SW recruits on January $1^{\text {st }}$ in the first sea winter. The model estimates the PFA from the catch in numbers of 1SW and MSW salmon in each country. These are raised to take account of minimum and maximum estimates of non-reported catches and exploitation rates of these two sea-age groups. Finally these values are raised to take account of the natural mortality between January $1^{\text {st }}$ in the first sea winter and the mid-point of the respective national fisheries. As reported in 2002 (ICES, 2002), the Working Group has determined a natural mortality value of 0.03 (range $0.02-0.04$ ) per month to be appropriate. A Monte Carlo simulation (10 000 trials) using ‘Crystal Ball v7.2.1’ in Excel (Decisioneering, 1996) is used to estimate confidence limits on the PFA values. Potter et al. (1998) provides full details of the model. Further modifications, to improve the model were incorporated during the Working Group meeting in 2005 (ICES, 2005).

### 3.8.10 Sensitivity of the PFA model

The sensitivity of the PFA and spawner estimates for the Northern and Southern European stock complexes was carried out using the tools within Crystal Ball. The relative contribution of model parameters to variance in the estimates of recruits (maturing and non-maturing 1SW) and spawner numbers (1SW and MSW) for both Northern and Southern NEAC stock complexes were estimated using the data presented to the ICES Working Group in 2007 (catch data for 2006). PFA estimates are particularly sensitive to the marine mortality parameter. This is due both to the range ( $0.02-0.04$ ) attributed to marine mortality in the Monte Carlo simulation and also to the time over which stocks are raised using the variable. Given a fixed value for M, parameters which have accounted for at least $5 \%$ of the variance of a given variable are shown in Table 3.8.10.1. Taking both stock complexes together these account for 11 (9\%) of the 117 parameters used to estimate PFA and 19 (26\%) of the 72 parameters used to estimate spawner numbers.

The sensitivity of forecast variables to these parameters has been shown to be remarkably consistent between years (ICES, 2006) and analysis of the data presented to the 2007 Working Group gave results which were similar to previous years.

### 3.8.11 National input to the NEAC-PFA model

To run the NEAC PFA model, most countries are required to input the following time-series information (beginning in 1971) for 1SW and MSW salmon:

- Catch in numbers
- Unreported catch levels (min and max)
- Exploitation levels (min and max)

The model input data are provided in Tables 3.8.11.1(a-t). For some countries, the data are provided in two or more regional blocks. In these instances, the model output is combined to provide one set of output variables per country.

The model input data for Finland consists solely of catches from the River Tana/Teno. These comprise both Finnish and Norwegian net and rod catches. The Norwegian catches from the River Tana/Teno are not included in the Norway data.

Descriptions of how the model input has been derived were presented in detail at the Working Group meeting in 2002 (ICES, 2002). Modifications are reported in the year in which they are
first implemented and significant modifications undertaken in 2007 are indicated in Section 3.7.1.

The Working Group noted that some countries were developing PFA models for national management. For example, in Norway, the development of national PFA estimates has been initiated, and some provisional modification to the NEAC model is proposed. The NEAC model uses total exploitation rate. In Norway it is more appropriate to use freshwater exploitation rate, as there are more data available and they are easier to estimate. In contrast to the NEAC model the Norwegian catch in the River Tana is included. The output from the Norwegian model was similar to the results for Norway from the NEAC model.

### 3.8.12 Description of national stocks as derived from the PFA model

The Working Group has previously noted that the NEAC PFA model provides our best interpretation of available information on national salmon stocks. However, there remains considerable uncertainty around the derived estimates, and national representatives are continuing to improve the data inputs each year on the basis of new data, improved sampling and further analysis.

The National conservation limits model has been designed as a means to provide a preliminary CL reference point for countries where river-specific reference points have not been developed. These figures should also be regarded as uncertain and should only be used with caution in developing management options. A further limitation with a single national status of stocks analysis is that it does not capture variations in status in different fishery areas or stock complexes. This has been addressed, at least in part, by the area splits in some countries.

The model output for each country has been displayed as a summary sheet (Figures 3.8.12.1(a-j)) comprising the following:

- Estimated total returns and spawners (95\%confidence limits)
- Estimated total catch (including non-reported) of 1SW and MSW salmon.
- Estimated pre-fishery abundance (PFA) of maturing 1SW and non-maturing 1SW salmon (labelled as 1SW and MSW).
- Total exploitation rate of 1SW and MSW salmon estimated from the total returns and total catches derived from the model.
- National pseudo stock-recruitment relationship (PFA against lagged egg deposition), with CL fitted by the method presented in ICES (2001) for those countries where CLs are not estimated using river specific CLs.

### 3.8.13 Trends in the PFA for NEAC stocks

Tables 3.8.13.1-3.8.13.6 show combined results from the PFA assessment for the NEAC area. The PFA of maturing and non-maturing 1SW salmon and the numbers of 1SW and MSW spawners for the Northern and Southern European groups are shown in Figure 3.1.1.

The 95\% confidence limits (dotted lines for PFA and vertical bars for the spawning escapement) (Figure 3.1.1) indicate the uncertainty in this assessment procedure. The Working Group recognised that the model provides an index of the current and historical status of stocks based upon simple catch and fisheries parameters (i.e. catch and exploitation rate). Errors or inconsistencies in the output largely reflect uncertainties in our best estimates of these parameters.

Recruitment patterns of maturing 1SW salmon and of non-maturing 1SW recruits for Northern Europe (Figure 3.1.1) show broadly similar patterns. The general decline over the time period is interrupted by a short period of increased recruitment from 1998 to 2003. Both stock complexes have been at full reproductive capacity prior to the commencement of distant water fisheries throughout the time series.

Trends in spawner number for the Northern stock complexes for both 1SW and MSW are similar. Throughout most of the time series, both 1SW and MSW spawners have been either at full reproductive capacity (as in 2006) or at risk of reduced reproductive capacity. This is broadly consistent with the general pattern of decline in marine survival of 1SW and 2SW returns in most monitored stocks in the area (Section 3.8.14).

Recruitment patterns of maturing 1SW salmon and of non-maturing 1SW recruits for Southern Europe (Figure 3.1.1) show broadly similar declining trends over the time period. The maturing 1SW stock complex has been at full reproductive capacity over the time period with the exception of 2006 when it is at risk of suffering reduced reproductive capacity after homewater fisheries have taken place. The non-maturing 1SW stock has been at full reproductive capacity over most of the time period but has been at risk of suffering reduced reproductive capacity after homewater fisheries have taken place in five of the nine years since 1996.

Declining trends in spawner number are evident in the Southern stock complexes for both 1SW and MSW. However the 1SW stock has been at risk of reduced reproductive capacity or suffering reduced reproductive capacity for most of the time series. In contrast the MSW stock has been at full reproductive capacity for most of the time series until 1997 when this stock has been either at risk of reduced reproductive capacity or suffering reduced reproductive capacity. This is broadly consistent with the general pattern of decline in marine survival of 1SW and 2SW returns in most monitored stocks in the area (Section 3.8.14).

### 3.8.14 Survival indices for NEAC stocks

An overview of the trends of marine survival for wild and hatchery-reared smolts returning to homewaters (i.e. before homewater exploitation) for the 2005 and 2004 smolt year classes (returning 1SW and 2SW salmon, respectively) is presented in Figure 3.8.14.1. The survival indices presented are the annual rates of change in marine survival. The original survival indices for different rivers and experimental facilities are presented in Tables 3.8.14.1 and 3.8.14.2.

An overall trend in both Northern and Southern NEAC areas, both wild and hatchery smolts, show a decline in marine survival with the annual decline varying between $1 \%$ and $13 \%$ (Figure 3.8.14.1). Most of the survival indices for wild smolts were lower than those of previous year but higher or at the 5- and 10-year averages. Most of the survival indices for the hatchery-reared smolts were below the 5- and 10-year averages, although many figures were at or higher than those of the previous year (Table 3.8.14.2). Return rates of hatchery released fish, however, may not always be a reliable indicator of marine survival of wild fish.

Results from these analyses are consistent with the information on estimated returns and spawners as derived from the PFA model (Section 3.8.13), and suggest that returns are strongly influenced by factors in the marine environment.

### 3.8.15 Exploitation indices for NEAC stocks

Exploitation estimates have been charted for 1SW and MSW salmon from the northern and southern NEAC areas for the period 1971-2006 (1983-2006 for Norway) and are displayed in Figures 3.8.15.1 and 3.8.15.2. These figures have been collated from the NEAC pre-fishery abundance model and represent an estimate of total national exploitation rates inclusive of both commercial and recreational fisheries (catches at Faroes and West Greenland are not included). Data gathered prior to the 1980's represent estimates of national exploitation rates whilst post 1980's exploitation rates have often been subject to more robust analysis informed by projects such as the national coded wire programme in Ireland. The overall rate of change of exploitation within the different countries in the NEAC area has been presented as a plot of the relative change (\% change per year) in exploitation rate over the time series. This was
derived from the slope of the linear regression between time and natural logarithm transformed exploitation rate (Figures 3.8.15.3 and 3.8.15.4).

The exploitation of 1SW salmon in both northern and southern NEAC areas has shown a general decline over the time series (Figure 3.8.15.1 and 3.8.15.2). Exploitation rates on 1SW salmon were $41 \%$ and $29 \%$ respectively in 2006 representing a decrease on the previous 10 year averages of $43 \%$ and $35 \%$ in northern and southern areas. The exploitation rate of MSW fish also exhibited an overall decline over the time series in both northern and southern areas (Figure 3.8.15.1 and 3.8.15.2). The area averages for north and south NEAC regions was 48\% and $34 \%$ in 2006 reflecting a decrease on the previous 10 year averages of $52 \%$ and $35 \%$ respectively.

The rate of change of exploitation in the northern NEAC area is charted in Figure 3.8.15.3 and shows an overall reduction of exploitation in all countries for MSW fish with the greatest decrease measured in Norway. Exploitation of 1SW fish in Finland has been relatively stable over the time period whilst the largest rate of reduction has been for 1SW salmon in Russia. The southern NEAC countries (Figure 3.8.15.4) have also shown a general decrease in exploitation rate on both 1SW and MSW salmon with the greatest rate of decrease measured for both 1SW and MSW fish in UK (Scotland). A fairly large rate of decrease of exploitation in 1SW salmon was also noted in UK (Northern Ireland) whilst the only positive change indicative of increasing exploitation was detected on 1SW fish in France (Figure 3.8.12.1b).

### 3.9 NASCO has requested ICES to provide any new information on the extent to which the objectives of any significant management measures introduced in recent years have been achieved

In 2005, the Working Group noted the implications for salmon stocks arising from the implementation of Council Directive 92/43/EEC (on the conservation of natural habitats and of wild flora and fauna). States are obliged to take measures to ensure that the exploitation of salmon stocks is compatible with their being maintained at a favourable conservation status. Under the terms of the Directive, every 6 years member states are obliged to submit a report detailing the conservation status of their salmon stocks. The first such report is due to be submitted in 2007.

The Working Group notes that salmon management in European Member States is becoming increasingly linked with the Water Framework Directive (Directive 2000/60/EC) (WFD), and its 6 year planning cycle. The WFD aims to protect and enhance the water environment, updates all existing relevant European legislation, and promotes a new approach to water management through river-based planning. The Directive requires the development of River Basin Management Plans (RBMP) and Programmes of Measures (PoM) with the aim of achieving Good Ecological Status or, for artificial or more modified waters, Good Ecological Potential.

Member States will need to identify River Basin Districts (RBDs), which will be 'characterised' by assessing the pressures and impacts on the water environment, such as overuse or pollution. Once that is complete, a RBMP for each District will be prepared setting out how these impacts will be reduced through its PoM. Monitoring programmes will then chart progress towards achievement of Good Ecological Status. RBMPs and PoMs need to be agreed, finalised and published by December 2009 for the first round of the WFD planning cycle. The second round plans are to be published in 2015. The status of migratory species and access to habitats will be important elements to take into account when assessing Good Ecological Status.

## Summary of country inputs

Most management measures introduced in recent years in relation to international, national and local objectives have aimed to reduce levels of exploitation on NEAC stocks, to increase
freshwater escapement and in some countries specifically to meet river specific CLs. Although some local measures have had notable success (Table 3.9.1), the two southern NEAC stock complexes are currently suffering reduced reproductive capacity after homewater fisheries have taken place.

### 3.10 NASCO has requested ICES to provide estimates of by-catch and non-catch fishing mortality of salmon in pelagic fisheries with an assessment of impacts on returns to homewaters

### 3.10.1 SGBYSAL

Disaggregated pelagic fisheries data (eg. by weeks, gear types, etc.) are generally available from most countries who have important fisheries in the Nordic Seas. In contrast, there have not been any dedicated investigations on distribution of postsmolts and salmon since 2005 in this area. Therefore, without data on salmon distribution or regularly occurring reliable reports on by-catches, it is not possible to provide updated estimates of by-catch. Consequently the Study Group on the Bycatch of Salmon in Pelagic Fisheries (SGBYSAL) was dissolved by ICES in 2006 and will only be reconvened when new and relevant information becomes available. However, the WGNAS continues to collate reports on salmon taken in commercial or research fisheries in order to document any increases in the frequencies of such reports and these are provided below. The above records do not supply enough information to allow an assessment of the effect of non-targeted fisheries on salmon abundance.

### 3.10.2 Bycatch of salmon in non-targeted catches in 2006

Norwegian research vessels have registered a bycatch of 46 post-smolts from one single haul and 7 larger salmon from three separate cruises (Figure 3.10.2). No salmon surveys were carried out in the Norwegian Sea in 2006.

Norwegian bycatch observers have not reported any salmon by-catches during routine screening of commercial catches.

Records were obtained of a by-catch of 12 larger salmon (from 1 to 12 kg ) from a commercial trawl fishery for cod north east of Bear Island during August and September 2006

Russian commercial catches screening reported a total of 9 salmon as follows:
In 2006 the screening program was carried out in the Norwegian Sea by FV M-0011 "Boris Syromyatnikov" while pelagic fishing for mackerel, blue whiting and herring from June 19 to September 16.

Four post-smolts (WT - 127-170 g) were found in a single catch of 40 tonnes of mackerel taken in international waters on the $27^{\text {th }}$ June. On July $2^{\text {nd }}$, one post-smolt ( $\mathrm{WT}-120 \mathrm{~g}$ ) was found in a catch of 35 tonnes of mackerel. All post-smolts were caught when surface trawling at a depth of $0-50$ meters. One adult salmon (female, FL -54 cm , WT -3.5 kg ) was caught while fishing for herring

Two other commercial vessels reported Atlantic salmon by-catch while fishing for mackerel. One post-smolt (WT -130 g ) was found on the $7^{\text {th }}$ of July. One adult salmon (male, FL -52 cm , WT -2.0 kg ) was reported in the catch of another ship the same day. A third commercial vessel registered a Norwegian Carlin tagged postsmolt (FL-286 mm) in a herring catch on August 15 (Figure 3.10.2).

The above records do not supply enough information to allow an assessment of the effect of non-targeted fisheries on salmon abundance.

Table 3.3.2.1. Conservation limits for NEAC stock groups estimated from national lagged egg deposition model and from river specific values (where available).

|  | National | del CLs | River S | fic CLs | Conservatio | limit used |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

${ }^{\text {as }}$ Lower Adour only since 1994 (Southwester France), due to fishery closure in the Loire Basin.
${ }^{10}$ Adour estuary only (Southwestern France).
Number of fishermen or boats using drifit nets: overestimates the actual number of fishermen targeting salmon by a factor 2 or 3 .
Common licence for salmon and sea rout introduced in 1986 , leading to short-term increase in the number of licences issued.
Before 2000, equal to the number of salmon licenses sold. From 2000 onwards, number estimated because of a single sea trout and salmon angling license. $(2005 /$ mean -1$) * 100$

Table 3.8.8.2. Average exploitation rates in Ireland for selected English and Welsh salmon stocks, based on aggregated data for the periods before and after the introduction of management measures in the Irish fishery in 1997.

| River | Pre 1997 <br> Expl. Rate <br> (\%) |  |  | 95\% CL | Years | Post 1997 <br> Expl. Rate <br> $(\%)$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Years 95\% CL |  |  |  |  |  |
| Tyne - NE England | $1986-96$ | 1.3 | $\pm 0.4$ | 1997 | 0.5 | $\pm 0.7$ |
| Wear - NE England | $1986-96$ | 0.9 | $\pm 0.2$ | 1997 | 0 |  |
| Dee - N. Wales | $1992-96$ | 16.8 | $\pm 5.7$ | $1997-2005$ | 2.1 | $\pm 0.95$ |
| Taff - S. Wales | $1991-96$ | 13.4 | $\pm 4.6$ | $1997-2005$ | 8.2 | $\pm 3.5$ |
| Tamar - SW England |  | No data |  | $2003-2005$ | 1.6 | $\pm 1.3$ |
| Test - S. England | $1991-96$ | 28.4 | $\pm 5.9$ | $1997-2000$ | 12.0 | $\pm 4.2$ |

Note: Pre 1997 data for the River Taff have been updated.

Table 3.8.10.1. Summary of the results of a sensitivity analysis of the NEAC run-reconstruction model. The relative contribution of model parameters to the variance in the predictions of the number of recruits (maturing and non-maturing 1SW) and spawners (1SW and MSW) for both Northern and Southern NEAC stock complexes were estimated using the data presented to the ICES Working Group in 2007 ( 2006 catches). Parameters which have accounted for at least $5 \%$ of the variance of a given forecast variable in one or more years are indicated by $\mathbf{X}$.

Table 3.8.11.1a. Input data for NEAC Pre Fishery Abundance analysis using Monte Carlo simulation - R. Tana/Teno (Finland/Norway).

Table 3.8.11.1b. Input data for NEAC Pre Fishery Abundance analysis using Monte Carlo simulation - France.

Table 3.9.1. Summary of national objectives, recent management measures and attainment of management objectives.

| Country | Objective | Measure | Assessment | Outcome/extent achieved | Further consideration |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Russia | Reduce commercial fishing effort and enhance recreational catch and release fisheries | Various management measures including prohibition of some important commercial in-river fisheries and allocation quotas for fisheries | Examination of catch statistics | Mean total commercial catch reduced by $38 \%$ and mean in-river commercial catch reduced by $67 \%$ (2002-2006 compared to 1997-2001). Catch and release increased twice in past 5 years | Further reductions likely to be introduced |
| Ireland | Reduce exploitation rates and increase freshwater returns leading to simultaneous attainment of CLs in all rivers | TAC imposed in 2002 which has been reduced by $17 \%, 11 \%, 14 \%$ and $35 \%$ annually or $58 \%$ in total. Restrictions in angling catch including bag limits and mandatory catch and release operated from the 1st of September in 8 fishery districts which were assessed as being below their Conservation Limits | Examination of coded wire tagging returns to Irish and UK rivers pre and post imposition of TACs | Exploitation rate reduced from 61\% (pre2002) to $46 \%$ (post 2002) for wild salmon, $82 \%$ to $69 \%$ for hatchery salmon Exploitation rate on UK stocks reduced by up to $50 \%$ following management measures in 1997 and imposition of TACs | Mixed stock marine fisheries will not operate in 2007 and hereafter. |
|  | Maintain salmon stocks in SAC rivers at favourable conservation status | As above | Examination of counter (14 rivers) or rod catch (16 rivers)data to assess CL compliance for 30 SAC rivers | Following re-apraisal in 2007 and with the closure of the irish mixed stock fishery at sea, 19 of 30 SAC rivers will probably meet CLs | Under the EU Water Framework Directive water quality and fish passage are expected to improve |
| UK (England \& Wales) | Safeguard MSW stock component <br> Stocks to meet or exceed CLs in at least 4 years of 5 | National spring salmon measures introduced in 1999 (restricted net fishing before June and required compulsory catch \& release by anglers up to June 16) <br> Mixed stock fishery measures imposed including phase outs, closures, buy outs and reductions in fisheries <br> Promote catch and release, including $100 \%$ catch and release in some catchments. | Estimated 1,000 salmon saved from net fisheries and 1,600 saved from rod fisheries in 2006 due to these measures | Spawning escapement of spring salmon may have increased by up to one third on some rivers due to measures | Measures will remain in place until at least 2008. |
|  |  |  | Examination of catch statistics and annual compliance | Coastal fishery catch reduced from average of $41,000(88-92)$ to under 32,000 (98-02) and to about 9,500 (03-06) Declared rod catch in 5 north east rivers $61 \%$ higher on average in the 4 years since net buy out in 2003, relative to average of 5 years before buy out. | Continuing to phase out remaining mixed stock fisheries and focus on other limiting factors. Annual application of decision structure to assess need for effort controls. |
|  |  |  | Examination of counters | Recorded runs (salmon + sea trout) into the Tyne 97\% higher since 2003 compared with mean of previous 5 years. | Continue monitoring |
|  |  |  | Examination of catch statistics, release rates and annual compliance | Catch and release increased to over 50\% of rod caught fish in recent years \& 100\% C\&R on some catchments. Estimated to have contributed an extra 34 million eggs in 2006. | Continuing promotion of C\&R at national and local levels. |

Table 3.9.1 Cont'd. Summary of national objectives, recent management measures and attainment of management objectives.

| Country | Objective | Measure | Assessment | Outcome/extent achieved | Further consideration |
| :---: | :---: | :---: | :---: | :---: | :---: |
| UK (England \& Wales) | To meet a management target on the River Lune of 14.4 million eggs or about 5,000 adults <br> Maintain salmon stocks in SAC rivers at favourable conservation status | Regulations on River Lune introduced in 2000 to reduce exploitation in net and rod fisheries by $50 \%$ and $25 \%$ respectively. <br> Fishing controls, catch and release and addressing issues identified in Salmon Action Plans as appropriate. | Assessment of counter data, catch statistics and juvenile monitoring data <br> Examination of counter/rod data to assess CL compliance for 18 rivers designated as SACs | Increase in salmon spawning and management target exceeded in all years since the regulation. Increases in juvenile production and net catch. <br> 2 are currently considered to be complying with the management objective of passing the CL 4 years out of 5 . | Contine to meet management objectives <br> Continue with management plan to meet management objectives. Targeted actions as identified in Salmon Action Plans. |
| UK (Northern Ireland) | To conserve, enhance, restore and manage salmon stocks in catchments throughout Northern Ireland through two Salmon Management Plans (FCB and Loughs Agency areas). | Voluntary net buyout scheme initiated in FCB area in 2001/2. <br> Introduction of conservation policies in angling byelaws including mandatory catch \& release before 1st June and bag limit of 2 salmon per day thereafter in the FCB area. <br> Rational management of fishery in Loughs Agency area based on compliance against temporal management targets with statutory instruments to increase/decrease inseason effort accordingly. <br> Introduction of salmon management plan in FCB area to facilitate monitoring against CL's. | Examination of fish counter \& rod catch data to assess spawning escapement on index rivers with defined CLs <br> Examination of juvenile electric fishing assessments in-river habitat surveys <br> Assessment of commercial and recreational exploitation through a carcass tagging scheme in both FCB and Loughs Agency areas. <br> Examination of CWT data to assess exploitation/survival rates. | Homewater exploitation in FCB area reduced from around 10,542 fish per year (1992-2001) to about 2,852 salmon per year (2002-06). | Continue monitoring and management protocols under the salmon management plans. <br> Continue to develop salmon management plans on other major catchments to define CLs and compliance monitoring mechanisms. <br> Monitor effect of habitat enhancement schemes. |

Table 3.9.1. Cont'd. Summary of national objectives, recent management measures and attainment of management objectives.

| Country | Objective | Measure | Assessment | Outcome/extent achieved | Further consideration |
| :---: | :---: | :---: | :---: | :---: | :---: |
| UK (Scotland) | Improve status of early running MSW salmon | Agreement by Salmon Net Fishing Association to delay fishing to beginning of April from 2000 <br> Bervie, N.and S. Esk salmon district net fishery delayed til May with catch and release only until June | Examination of catch statistics <br> Examination of catch statistics | $80 \%$ reduction in MSW net fishery catch in February to March relative to previous 5 yr mean <br> Believed to have increased escapement | Further reduction in exploitation |
|  |  |  |  |  | Measure in place for 5 years. Reevaluation after this period |
| France | Reduce exploitation on MSW in particular and increase escapement and compliance with river specific CLs | Closure since 1994 of Loire-Allier sport and commercial fisheries | Measured against compliance objectives for the area | This did not seem to enhance salmon numbers | Physical obstructions (noticeably Poutès-Monistrol Hydropower Dam) and other environmental factors, including higher temperatures, also being considered |
|  |  | TACs introduced in 1996 in Brittany and Lower Normandy MSW TACs have lead to temporary closures on some rivers | Examination of catch statistics | Reduced catch and probably increased in spawning numbers. Reduced catch in MSW catch in Brittany since 2000 and Lower Normandy since 2003 | Monitored river (Scorff) has failed to meet CL consistently since 1994. However, the Scorff is non typical of exploitation pattern in the area (small fishery) |
|  |  | Management measures in the AdourGaves basin in 1999 and '2003 | Examinaton of catch statistics | Some reduction in rod catch but current regulations have been unable to reduce the exploitation rate on MSW stocks as expected | Rod catch increased in 2004 and 2005 when measures lapsed with steady increase in effort and catch of estuary drift net fishery for 1999 to 2004 |
| Germany | Reintroduction of Atlantic salmon Salmon stocks extinct since the middle of 20th century but improvements in conditions and water quality were thought to be sufficient to support salmon | Restocking of rivers running into North Sea (Rhine, Ems, Weser and Elbe). 2 million juveniles (mainly fry) released annually | Trap and counter data (Sieg, upper Rhine) | 200-500 adults recorded annually. Return rates of less than $1 \%$ | Low return rates thought to reflect obstructions to migration in the Rhine delta as well as spawning tributaries and probably due to bye-catch in non-target fisheries |
|  | Establish free migration routes for salmon and other migratory fishes and rehabilitation of habitat in rivers basins | Collaborative programme has started e.g. Rheinprogramm 2020 (ICPR) International Commision for the Protection of the River Rhine | Assessment in progress | Assessment in progress |  |

## 4 North American Commission

### 4.1 Status of stocks/exploitation

In 2006, the midpoint of the 2SW spawner estimates for six geographic areas indicated that all areas except Newfoundland were below their conservation limit (Figure 4.9.7.3) and are suffering reduced reproductive capacity. Newfoundland was at risk of suffering reduced reproductive capacity.

The estimated exploitation rate of North American origin salmon in NAC fisheries has declined (Figure 4.9.6.1) from approximately $80 \%$ to $17 \%$ for 2 SW salmon and from approximately $60 \%$ to $17 \%$ for 1 SW salmon.

The stock status is elaborated in Section 4.9.

### 4.2 Management objectives

Management objectives are included in Section 1.4.

### 4.3 Reference points

There are no changes recommended in the 2SW salmon conservation limits (CLs) from those identified previously. CLs for 2SW salmon for Canada total 123349 and for the USA, 29199 for a combined total of 152548.

| Country and <br> Comission Area | Stock Area | 2SW spawner <br> requirement |
| :--- | :--- | ---: |
|  | Labrador | 34746 |
|  | Newfoundland | 4022 |
|  | Gulf of St. | 30430 |
|  | Lawrence | 29446 |
|  | Québec | 24705 |
|  | Scotia-Fundy | 123349 |
| Canada Total |  | 29199 |
| USA | 152548 |  |
| North American |  |  |

### 4.3.1 Conservation Requirements for Labrador

The current conservation requirement for Labrador was developed from maximum total harvests and an assumed recruit per spawner factor of three. The current standard conservation requirement of 240 eggs per $100 \mathrm{~m}^{2}$ of parr-rearing habitat that is used for some Eastern Canadian rivers has not been applied to Labrador because of the lack of river specific production areas and because this rate may be unsuitable. Labrador rivers are more northerly and are exposed to a much colder climate than rivers than where the rate was derived. As a result of the colder climate, Labrador salmon generally have older smolt ages and therefore longer freshwater residency which could affect the conservation requirement. Also, many Labrador rivers have abundant anadromous charr (Salvelinus alpinus L.) and trout (Salvelinus fontinalis Mitchill) which are more abundant than in rivers to the south and may compete with salmon in freshwater for space and food. The preferred approach to defining biological reference points is through the analysis of stock and recruit relationships (SR). Development of reference points, such as conservation requirements, from SR time series requires a number of years of measured spawners and adult returns which have not been collected for any Labrador river.

The Working Group was informed of a publication (Reddin et al., 2006) that utilized local and regional data to develop three conservation reference point values for Labrador rivers. The first approach was based on a quasi-stock and recruit method and used fishery generated SR data previously developed for ICES to assess the returns and spawners in the Labrador. The second considered measured smolt production from Sand Hill River adjusted to variable freshwater survival rates developed in Newfoundland to derive comparable rates for Sand Hill River. The third was based on re-constructed SR data derived from angling catch rates from years when a counting fence was operated. The re-constructed SR data was used to estimate a conservation requirement at $50 \%$ of the equilibrium population. Results from the three methods indicated 161 ( $95 \%$ CL 110 to 309) eggs per $100 \mathrm{~m}^{2}$ for the quasi-SR approach, 152 ( $95 \%$ CL 80 to 370) eggs per $100 \mathrm{~m}^{2}$ based on the Sand Hill smolt production data and 187 ( $95 \%$ CL 153 to 201) from the SR analysis of Sand Hill River fence and angling data. Based on the data and analysis and until more information can be collected at higher escapements, it was decided that a CL of 190 eggs per $100 \mathrm{~m}^{2}$ be adopted.

The Working Group noted that these new rates will only be used for river specific salmon management and not for international fisheries management at this time. The Working Group encouraged the development of conservation requirements based on local information but noted that application of these rates was dependent on quantification of local juvenile salmon production areas that are currently unavailable for Labrador. The Working Group also encouraged the comparison of any new conservation requirements to that currently used which was developed from past high yields and assumed escapements that led to those yields.

### 4.4 Management advice

As the predicted number of 2SW salmon returning to North America in 2007 is substantially lower than the 2SW CL there are no catch options for the composite North American fisheries. Where spawning requirements are being achieved, there are no biological reasons to restrict the harvest.

Wild salmon populations are now critically low in an extensive portions of North America and remnant populations require alternative conservation actions to fisheries regulation to maintain their genetic integrity and their persistence.

Advice regarding management of this stock complex in the fishery at West Greenland is provided in Section 5.

### 4.5 Relevant factors to be considered in management

ICES considers that management for all fisheries should be based upon assessments of the status of individual stocks. Fisheries on mixed stocks, particularly in coastal waters or on the high seas, pose particular difficulties for management as they cannot target only stocks that are at full reproductive capacity. Conservation would be best achieved if fisheries target stocks that have been shown to be at full reproductive capacity. Fisheries in estuaries and especially rivers are more likely to meet this requirement.

### 4.6 Updated forecast of 2SW maturing fish for 2006

Catch options are only provided for the non-maturing 1SW and maturing 2SW components as the maturing 1 SW component is not fished outside home waters, and in the absence of significant marine interceptory fisheries, is managed in home waters.

It is possible to provide catch options for the North American Commission area for four years. The updated forecast for 2007 for 2SW maturing fish is based on an updated forecast of the 2006 pre-fishery abundance and accounting for fish which were already removed from the cohort by fisheries in Greenland and Labrador in 2006 as 1SW non-maturing fish. The
estimates for the 2008-2010 fisheries on maturing 2SW salmon are based on the pre-fishery abundance forecast for 2007-2009 from Section 4.9.10.

### 4.6.1 Catch options for 2007 fisheries on 2SW maturing salmon

The updated forecast of the pre-fishery abundance for 2006 provides a PFA mid-point of 117 431, about $1 \%$ lower than the forecast last year. The 2006 pre-fishery abundance of maturing 2SW salmon will be available in homewaters in 2007.

To compare the PFA to CLs, the pre-fishery abundance of 117431 fish can be expressed as 2SW equivalents by considering natural mortality of $3 \%$ per month for 11 months resulting in 84424 2SW salmon equivalents. There have already been harvests of this cohort as 1SW nonmaturing salmon in 2006 for both the Labrador ( 744 midpoint of estimates) and Greenland (4 286) fisheries (Table 4.9.10.3). Adjusted for natural mortality these catches equate to 3616 2SW salmon equivalents which potentially leaves 80808 2SW salmon to return to rivers in North America in 2007.

As the predicted number of 2SW salmon returning to North America in 2007 is substantially lower than the 2SW CL of 152 548, there are no catch options at probability levels of $75 \%$. Catch options refer to the composite North American fisheries. As the biological objective is to have all rivers reaching their conservation requirements, river-by-river management is necessary. On individual rivers, where spawning requirements are being achieved, there are no biological reasons to restrict the harvest.

### 4.7 Catch options for 2008-2010 for non-maturing 1 SW

Catch options derived from the pre-fishery abundance forecast for 2007-2009 apply to North American fisheries in 2008-2010. Accounting for potential catches in 2007-2009 at West Greenland, and natural mortality to home waters, the management objective to achieve conservation escapements, (assuming a sharing arrangement of $40 \%$ of the surplus West Greenland and $60 \%$ to North America) the only risk averse catch option for 2SW salmon in 2008-2010 is zero catch on the composite North American stock.

### 4.8 Comparison with previous assessment and advice

The updated forecast of the pre-fishery abundance for 2006 provides a PFA mid-point of 117000 fish. This is unchanged (-1\%) from the value forecast last year at this time of 119000 fish. This is mainly due to slight changes in the input values to the model used to forecast PFA for these stocks as well as changes in the parameter values resulting from the additional year of PFA and lagged spawner values used in the model.

### 4.9 NASCO has requested ICES to describe key events of the 2006 fisheries and the status of the stocks

### 4.9.1 Key events of the 2006 fisheries

- The majority of harvest fisheries were directed to small salmon.
- $95 \%$ of the harvest was taken in rivers or estuaries and $5 \%$ was taken in coastal waters.
- Harvest was 35171 salmon in 2006, down $22 \%$ from the five year mean.
- Catches remain low relative to pre 1990 values.

### 4.9.2 Harvest of North American salmon, expressed as 2SW salmon equivalents

Harvest histories (1972-2006) of salmon, expressed as 2SW salmon equivalents are provided in Tables 4.9.1.1. The Newfoundland-Labrador commercial fishery historically was a mixed
stock fishery and harvested both maturing and non-maturing 1SW salmon as well as 2SW maturing salmon. The harvest in these fisheries of repeat spawners and older sea-ages was not considered in the run reconstructions.

Harvests of 1SW non-maturing salmon in Newfoundland-Labrador commercial fisheries have been adjusted by natural mortalities of $3 \%$ per month for 13 months, and 2SW harvests in these same fisheries have been adjusted by one month to express all harvests as 2SW equivalents in the year and time they would reach rivers of origin. Starting in 1998, the Labrador commercial fishery was closed. Aboriginal Peoples' fisheries in Labrador (19982006) have been included. As well, a residents' food fishery in Labrador which started in 2000 is included. Mortalities (principally in fisheries) in mixed stock and terminal fisheries areas in Canada are summed with those of USA to estimate total 2SW equivalent mortalities in North America. The terminal fisheries included coastal, estuarine and river catches of all areas, except Newfoundland and Labrador where only river catches were included. Harvest equivalents within North America peaked at about 365000 in 1976 and are now about 11300 2SW salmon equivalents.

In the most recent year, the harvest of cohorts destined to be 2SW salmon in terminal fisheries of North America was $73 \%$ of the total catch. The values ranged from 20 to 31\% in 1972-1982 to $73-91 \%$ in 1996-2006 (Table 4.9.1.1). Percentages increased significantly since 1992 with the reduction and closures of the Newfoundland and Labrador commercial mixed stock fisheries. The number of 2SW salmon equivalents taken in the food fisheries in Labrador was 3073 fish in 2006.

### 4.9.3 Gear and effort

## Canada

The 23 areas for which the Department of Fisheries and Oceans (DFO) manages the salmon fisheries are called Salmon Fishing Areas (SFAs); for Québec, the management is delegated to the Ministère des Ressources naturelles et de la Faune and the fishing areas are designated by Q1 through Q11 (Figure 4.9.3.1). Harvest (fish which are retained) and catches (including harvests and fish caught-and-released in recreational fisheries) are categorized in two size groups: small and large. Small salmon, generally 1SW, in the recreational fisheries refer to salmon less than 63 cm fork length, whereas in commercial fisheries, it refers to salmon less than 2.7 kg whole weight. Large salmon, generally MSW, in recreational fisheries are greater than or equal to 63 cm fork length and in commercial fisheries refer to salmon greater than or equal to 2.7 kg whole weight.

Three groups exploited salmon in Canada in 2006: Aboriginal peoples, residents fishing for food in Labrador, and recreational fishers. There were no commercial fisheries in Canada in 2006.

Most catches (82\%, Figure 2.1.1.2) in North America now take place in rivers or in estuaries. Fisheries are principally managed on a river-by-river basis and, in areas where retention of large salmon is allowed, it is closely controlled. The commercial fisheries are now closed and the remaining coastal food fisheries in Labrador are mainly located close to river mouths and likely harvest few salmon from other than local rivers.

The following management measures were in effect in 2006.

## Aboriginal peoples' food fisheries

In Québec, Aboriginal peoples’ food fisheries took place subject to agreements or through permits issued to the bands. There are 10 bands with subsistence fisheries in addition to the fishing activities of the Inuit in Ungava (Q11), who fished in estuaries or within rivers. The permits generally stipulate gear, season, and catch limits. Catches in food fisheries have to be
reported collectively by each Aboriginal user group. However, if reports are not available, the catches are estimated. In the Maritimes (SFAs 15 to 23), food fishery harvest agreements were signed with several Aboriginal peoples groups (mostly First Nations) in 2006. The signed agreements often included allocations of small and large salmon and the area of fishing was usually in-river or estuaries. Harvests that occurred both within and outside agreements were obtained directly from the Aboriginal peoples. In Labrador (SFAs 1 and 2), food fishery arrangements with the Nunatsiavut Government, the Innu First Nation, and the Labrador Metis Nation, resulted in fisheries in estuaries and coastal areas. There are further details on the Labrador Aboriginal fisheries in Section 4.9.5. By agreement with First Nations there were no food fisheries for salmon in Newfoundland in 2006. Harvest by Aboriginal peoples with recreational licenses is reported under the recreational harvest categories.

## Residents food fisheries in Labrador

In 2006, a licensed food fishery for local residents took place, using gillnets, in Lake Melville (SFA 1) and in estuary and coastal areas of southern Labrador (SFA 2). Residents who requested a license were permitted to retain a maximum of four salmon of any size while fishing for trout and charr; four salmon tags accompanied each license. All licensees were requested to complete logbooks.

## Recreational fisheries

Licenses are required for all persons fishing recreationally for Atlantic salmon. Gear is generally restricted to fly fishing and there are restrictive daily/seasonal bag limits. Recreational fisheries management in 2006 varied by area (Figure 4.9.3.2). Except in Québec and Labrador (SFA 1 and some rivers of SFA 2), only small salmon could be retained in the recreational fisheries.

## USA

In the USA there was a one month fall catch and release recreational fishery for sea-run Atlantic salmon on a 2 km reach on one river in 2006. This is the first recreational fishery on sea-run Atlantic salmon in the USA since closures in 1999. A total of 241 licenses were sold and there were 247 angler trips reported.

## France (Islands of Saint-Pierre and Miquelon)

Licenses remained consistent with previous years at 14 professional and 48 recreational gill net fishers. The time series of available data is below:

| YEAR | NUMBER OF <br> PROFESSIONAL <br> LICENSES | NUMBER OF <br> RECREATIONAL <br> LICENSES |
| :--- | :---: | :---: |
| 1995 | 12 | 42 |
| 1996 | 12 | 42 |
| 1997 | 6 | 36 |
| 1998 | 9 | 42 |
| 1999 | 7 | 40 |
| 2000 | 8 | 35 |
| 2001 | 10 | 42 |
| 2002 | 12 | 42 |
| 2003 | 12 | 42 |
| 2004 | 13 | 42 |
| 2005 | 14 | 52 |
| 2006 | 14 | 48 |

### 4.9.4 Catches in 2006

## Canada

The provisional harvest of salmon in 2006 by all users was 132 t , about $5 \%$ lower than the 2005 harvest (Table 2.1.1.1; Figure 4.9.4.1). The 2006 harvest was 44233 small salmon and 11131 large salmon, $7 \%$ less small salmon and $2 \%$ more large salmon, compared to 2005 (Annex 4). The dramatic decline in harvested tonnage since 1988 is in large part the result of the reductions in commercial fisheries effort, the closure of the insular Newfoundland commercial fishery in 1992, the closure of the Labrador commercial fishery in 1998, and the closure of the Québec commercial fishery in 2000. These reductions were introduced as a result of declining abundance of salmon.

## Aboriginal peoples' food fisheries

Harvests in 2006 (by weight) were up $11 \%$ from 2005 and $6 \%$ lower than the previous 5-year average harvest.

| AbORIGINAL PEOPLES' FOOD FISHERIES |  |  |  |
| :--- | :---: | :---: | :---: |
| Year | Harvest (t) | \% large |  |
|  |  | by weight | by number |
| 1990 | 31.9 | 78 |  |
| 1991 | 29.1 | 87 |  |
| 1992 | 34.2 | 83 |  |
| 1993 | 42.6 | 83 |  |
| 1994 | 41.7 | 83 | 58 |
| 1995 | 32.8 | 82 | 56 |
| 1996 | 47.9 | 87 | 65 |
| 1997 | 39.4 | 91 | 74 |
| 1998 | 47.9 | 83 | 63 |
| 1999 | 45.9 | 73 | 49 |
| 2000 | 45.7 | 68 | 41 |
| 2001 | 42.1 | 72 | 47 |
| 2002 | 46.3 | 68 | 43 |
| 2003 | 44.3 | 72 | 49 |
| 2004 | 60.8 | 66 | 44 |
| 2005 | 56.7 | 57 | 34 |
| 2006 | 58.9 | 63 | 42 |

## Residents fishing for food in Labrador

The estimated total catch for the fishery in 2006 was 2.6 t , about 1052 fish ( $73 \%$ small salmon by number).

## Recreational fisheries

Harvest in recreational fisheries in 2006 totalled 35171 small and large salmon, 22\% below the previous 5 -year average, $8 \%$ below the 2005 harvest level, and the lowest total harvest reported (Figure 4.9.4.2). The small salmon harvest of 32171 fish was $5 \%$ below 2005 and $22 \%$ below the previous 5 -year mean. The large salmon harvest of 3000 fish was $31 \%$ below the previous five-year mean and $27 \%$ below 2005. The small salmon size group has contributed $88 \%$ on average of the total harvests since the imposition of catch-and-release recreational fisheries in the Maritimes and insular Newfoundland (SFA 3 to 14B, 15 to 23) in 1984.

In 2006, about 49279 salmon (about 21186 large and 28093 small) were caught and released (Table 4.9.4.1), representing about $58 \%$ of the total number caught, including retained fish. This was a $22 \%$ decrease from the number released in 2005. There is some mortality on these released fish, which is accounted for in rivers assessed for their attainment of CLs.

## Commercial fisheries

All commercial fisheries for Atlantic salmon remained closed in Canada in 2006 and the catch therefore was zero. Catches have decreased from a peak in 1980 of almost 2500 t to zero as a result of effort reductions, low abundance of stocks, and closures of fisheries.

## Unreported catches

Canada's unreported catch value for 2006 was 56 t . Estimates were incomplete at the time of the Working Group and therefore the value for 2006 is incomplete.

The unreported catch estimates for 2006 in tonnes were:

| STOCK AREA | UnREPORTED CATCH (t) |
| :--- | :---: |
| Labrador | $<1$ |
| Newfoundland | $<1$ |
| New | 39 |
| Brunswick |  |
| Nova Scotia | 1 |
| Québec | 16 |
| Total | 56 |

## USA

Unreported catches in the USA were estimated to be 0 t .

## France (Islands of Saint-Pierre and Miquelon) harvests

The harvest totalled 3.6 t of salmon in 2006 the highest in the time series. The time series of available data is below:

| Year | Professional <br> Licenses (T) | Recreational <br> Licenses (T) | Total (T) |
| :--- | ---: | ---: | ---: |
| $\mathbf{1 9 9 0}$ | 1.146 | 0.734 | 1.880 |
| $\mathbf{1 9 9 1}$ | 0.632 | 0.530 | 1.162 |
| $\mathbf{1 9 9 2}$ | 1.295 | 1.024 | 2.319 |
| $\mathbf{1 9 9 3}$ | 1.902 | 1.041 | 2.943 |
| $\mathbf{1 9 9 4}$ | 2.633 | 0.790 | 3.423 |
| $\mathbf{1 9 9 5}$ | 0.392 | 0.445 | 0.837 |
| $\mathbf{1 9 9 6}$ | 0.951 | 0.617 | 1.568 |
| $\mathbf{1 9 9 7}$ | 0.762 | 0.729 | 1.491 |
| $\mathbf{1 9 9 8}$ | 1.039 | 1.268 | 2.307 |
| $\mathbf{1 9 9 9}$ | 1.182 | 1.140 | 2.322 |
| $\mathbf{2 0 0 0}$ | 1.134 | 1.133 | 2.267 |
| $\mathbf{2 0 0 1}$ | 1.544 | 0.611 | 2.155 |
| $\mathbf{2 0 0 2}$ | 1.223 | 0.729 | 1.952 |
| $\mathbf{2 0 0 3}$ | 1.620 | 1.272 | 2.892 |
| $\mathbf{2 0 0 4}$ | 1.499 | 1.285 | 2.784 |
| $\mathbf{2 0 0 5}$ | 2.243 | 1.044 | 3.287 |
| $\mathbf{2 0 0 6}$ | 1.730 | 1.825 | 3.555 |

There are no unreported catch for France (Islands of Saint-Pierre and Miquelon).

### 4.9.5 Origin and composition of catches

In the past, salmon from both Canada and the USA were taken in the commercial fisheries of eastern Canada. These fisheries have been closed. The Aboriginal Peoples’ and resident food fisheries that exist in Labrador may intercept some salmon from other areas of North America although there are no reports of tagged fish being captured there in 2006. No information on the 2006 Saint-Pierre and Miquelon fishery, which harvests salmon of both USA and Canadian origin, was provided.

### 4.9.5.1 NASCO has asked ICES to provide a comprehensive description of coastal fisheries including timing and location of harvest, biological characteristics (size, age, origin) of the catch, and potential impacts on nonlocal salmon stocks.

In Canada all Aboriginal Peoples have a constitutional right to harvest for food social and ceremonial purposes. In 2006, there were four subsistence fisheries harvesting salmonids in Labrador: 1) Nunatsiavut Government (NG) members fishing in the northern Labrador communities of Rigolet, Makkovik, Hopedale, Postville, and Nain and in Lake Melville; 2) Innu Nation members fishing in Natuashish and in Lake Melville from the community of Sheshatshiu; 3) Labrador residents fishing in Lake Melville and coastal communities in southern Labrador from Cartwright to Cape St. Charles and, 4) LMN (Labrador Métis Nation) members fishing in southern Labrador from Fish Cove Point to Cape St. Charles.

The NG, Innu, and LMN fisheries were jointly regulated by Aboriginal Fishery Guardians administered under the Aboriginal Fisheries Strategy Program with the Department of Fisheries and Oceans (DFO) as well as by DFO Fishery Officers and Guardian staff. The new Nunatsiavut Government is directly responsible through the Torngat Fisheries Board for regulating its fishery through its Conservation Officers. DFO staff are also responsible for regulating the Resident Fishery.

## Description of the fisheries

The fishing gear is multifilament gillnets of 15 fathoms in length of a stretched mesh size ranging from 3 to 4 inches. Although nets are mainly set in estuarine waters some nets are also set in coastal areas usually within bays.

FSC fisheries catch statistics are based on log book reports and fisheries guardians. The overall reporting rate for subsistence fisheries, was 79\% in 2005 and 2006.

## Timing and location

Timing and location of the four FSC fisheries are described in 2006 Management Plans for these fisheries as follows:
NUNATSIAVUT GOVERNMENT (formerly LABRADOR
ASSOCIATION)

The conditions for the NG communal fishery were as follows:
Harvest Limits: each designated fisher has an allowance of 7 salmon for the fishing season for that portion of Labrador extending from Fish Cove Point, north to Cape Chidley, including Lake Melville (Zone 1). Once the 7 salmon are caught nets must be removed from the water or moved to an area where only charr have been historically caught.

Seasons: May 14 to July 9 and July 19 to August 14 in Goose Bay, North West River and Mud Lake, May 14 to August 31 in Rigolet, June 1 to August 31 in Makkovik and Postville, June 1 to September 30 in Hopedale and Nain.

## INNU NATION

The Community Guidelines for the Innu Nation fishery were as follows:
Harvest limits: There is an allowance of 3.0 t for the community of Sheshatsiu in Lake Melville and 0.5 t in the coastal community of Natuashish.

Season: mid-May to end of September.

## LABRADOR MÉTIS NATION

The conditions for the LMN Communal fishery were as follows:
Harvest limits: each designated fishery has an allowance of 6 salmon to be harvested for the season in the area from Fish Cove Point to Cape St. Charles. Once the 6 salmon are caught nets must be removed from the water.

Seasons: July 7 - August 15
RESIDENT SUBSISTENCE
The Management Plan for the Labrador Resident subsistence fishery was as follows:
Catch limits: four salmon per licence with a season limit of 50 trout. Once four salmon have been caught a fishers net must be removed from the water.

Seasons: July 11 to July 30 (Fish Cove Point to Bolsters Rock) and July 11 to July 23 (Bolsters Rock to Cape Charles) in southern Labrador, June 15 to July 2 and July 22 to August 6 (Kenamu closes July 30th) (Cape Rouge to Fish Cove Point (including Lake Melville)) and June 17 to July 3 (Cape Rouge to Davis Inlet) and July 1 to July 17 (Davis Inlet to Cape Chidley) in northern Labrador.

## Coastal versus estuary landings

The division of catch between coastal and estuary origins in Labrador FSCs was revised in 2006. Originally, when NASCO requested ICES to provide estimates of coastal versus estuary catches there was little information on fishing locations. In 2000-2005, coastal harvests were determined as all catches in FSCs in Labrador the exception of Lake Melville which was estuarine. In 2006, location was added to the FSC fishing logs, however, the number of logs that provided exact locations was limited. Consequently, Fishery Officers employed by Fisheries \& Oceans in Labrador as well as aboriginal enforcement staff were asked to provide proportions of catch in estuary and coastal areas based on their local knowledge of locations were salmon were caught. The definition used for an estuary was that of Pritchard (1967) which states that an estuary is a partly enclosed coastal body of water in which river water is mixed with seawater. These proportions are shown in Figure 4.9.5.2. The text table below compares the new breakdown of catches into estuary and coastal areas to the old proportions.

| Year | Weight (kg) |  |  | Percentages (kg) |  | $\frac{\text { Previous methods }}{\text { Percentages (kg) }}$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Estuarine | Coastal | Total | Estuarine |  | Estuarine | Coastal |
| 2000 | 13,278 | 2,335 | 15,613 | 85 | 15 | 38 | 62 |
| 2001 | 13,497 | 2,792 | 16,288 | 83 | 17 | 26 | 74 |
| 2002 | 13,987 | 3,585 | 17,572 | 80 | 20 | 23 | 77 |
| 2003 | 17,485 | 4,622 | 22,108 | 79 | 21 | 20 | 80 |
| 2004 | 24,862 | 6,787 | 31,649 | 79 | 21 | 23 | 77 |
| 2005 | 25,303 | 6,611 | 31,914 | 79 | 21 | 35 | 65 |
| 2006 | 23,169 | 7,073 | 30,242 | 77 | 23 | 30 | 70 |

The Working Group concluded that revised approach improved the assignment of fishing locations to estuarine and costal and encouraged the continued efforts to include more precise locations on the logbooks returned by fishers.

## Results of sampling program for Labrador FSCs

A sampling program was in place for the FSC fisheries in Labrador in 2006. Landed fish were sampled opportunistically. Fish were measured (fork length to the nearest cm), weighed (gutted weight or whole weight if available to the nearest $1 / 10$ th of a kg ) and if possible the sex was determined. Scales were taken for subsequent age analysis. In addition, fish were examined for the presence of external tags, brands or elastomer marks, and adipose fin clips. In southern Labrador, there were three persons hired by the Labrador Metis Nation to conduct the sampling. In northern Labrador, Conservation Officers of the Nunatsiavut Government conducted the sampling.

In total, 336 samples were collected that based on scale reading indicated $86 \% 1 \mathrm{SW}, 8 \% 2 \mathrm{SW}$ and $6 \%$ previously spawned salmon. Small and large salmon based on a 2.7 kg , similar to that used in the fishery, indicated small salmon were $95 \% 1 \mathrm{SW}, 2 \% 2 \mathrm{SW}$ and $3 \%$ previously spawned salmon and large salmon were $24 \% 1 \mathrm{SW}, 52 \% 2 \mathrm{SW}$ and $24 \%$ previously spawned salmon.

The river ages (Figure 4.9.5.1) of the FSC samples were compared to ages from scales obtained from adults at assessment four facilities in Labrador. Freshwater samples numbered 1946 from north Labrador and 975 in south Labrador.

There were no differences in river age distributions of adults from fisheries compared to returns to rivers in North (Chi-square $=4.64, \mathrm{P}=0.46$ ) or South Labrador (Chi-square=4.25, $\mathrm{P}=0.51$ ). Further, the freshwater age distribution did not differ (Chi-square $=2.32, \mathrm{P}=0.80$ ) between the two regions of Labrador.

The relative absence of age 1 and 2 smolts in the FSC catches in 2006 suggests that these fisheries did not exploit southern North America stocks to any extent. The presence of river age 5 to 7 years in the FSC samples provides evidence that the FSC fisheries are exploiting northern area (predominantly Labrador) stocks.

The Working Group noted that the sampling program conducted in 2006 provided significant improvement in the biological characteristics of the harvest as well as provide material for a an analysis about the origin of salmon in this fishery. Working Group recommended that sampling be repeated in future fisheries and if possible expand sampling to include other areas and increase the sample size.

### 4.9.6 Exploitation rates

## Canada

There is no directed exploitation by commercial fisheries. In the Newfoundland angling fishery, exploitation rates from retained small salmon ranged from a high of $12 \%$ on Torrent River to a low of $4 \%$ on Terra Nova River. Overall, exploitation of small salmon in these rivers declined from $30 \%$ in 1986 to $10 \%$ in 2006 and was the lowest in the 23 years. In Labrador, exploitation on small salmon was $3 \%$ at Sand Hill River. Exploitation on large salmon was less than $1 \%$.

## USA

There was no exploitation of USA salmon in home waters, and no tagged salmon of USA origin were reported in Canadian fisheries in 2006.

## Exploitation trends for North American salmon fisheries

Annual exploitation rates of 1SW and 2SW salmon in North America for the 1970 to 2006 time period were calculated by dividing annual harvests in all North American fisheries by annual estimates of the returns to all 6 regions of North America. The fisheries included coastal, estuarine and river fisheries in all areas, as well as the commercial fisheries of Newfoundland and Labrador which harvests salmon from all regions in North America.

Exploitation rates of both 1SW and 2SW salmon fluctuated annually but remained relatively steady until 1984 when exploitation of 2SW salmon declined considerably with the introduction of the non-retention of large salmon in angling fisheries and cuts to commercial fisheries (Figure 4.9.6.1). Exploitation of 1SW declined substantially in North America after 1991 with the closure of the Newfoundland commercial fishery in 1992. Declines continued in the 1990s with continuing management controls put in place in all fisheries to reduce exploitation. In the last two years, exploitation rates on 1SW salmon have declined to the lowest in the time series and 2SW are amongst the lowest. The exploitation rates across regions within North America are highly variable.

### 4.9.7 Elaboration on status of stocks

To date, approximately 550 Atlantic salmon rivers have been identified in eastern Canada and 21 rivers in eastern USA, each of which could contain at least one population of salmon. Assessments were prepared for 77 of these rivers in 2006.

### 4.9.7.1 Smolt and juvenile abundance

## Canada

Wild smolt production was estimated in 15 rivers in 2006. Of these, eight rivers have at least ten years of information (Figure 4.9.7.1).

In 2006, smolt production increased ( $>10 \%$ change) from 2005 in seven rivers, decreased in four rivers and remained unchanged in two rivers (Figure 4.9.7.1). The relative smolt production, scaled to the size of the river using the conservation egg requirements, was highest in the rivers of Québec and low in the southern rivers of the Scotia Fundy and USA areas. In the nine rivers monitored over at least the past ten years, there has generally been no significant linear change ( $\mathrm{P}>0.05$ ) in smolt production with the exception of a significant increase in Western Arm Brook (Newfoundland) and a significant decrease in River de la Trinite (Quebec) (Figure 4.9.7.1).

Juvenile salmon abundance has been monitored annually since 1971 in the Miramichi (SFA 16) and Restigouche (SFA 15) rivers and for shorter and variable time periods in a large
number of other rivers in the Maritime Provinces. In the rivers of the southern Gulf of St. Lawrence, densities of young-of-the-year (age $0+$ ) and parr (age- $1+$ and $2+$ ) have increased since 1985 in response to increased spawning escapements and densities of fry and parr in 2006 remained at high values. Rivers in SFAs 20 and 21 along the Atlantic coast of Nova Scotia are high in dissolved organics, have low productivity, and influenced by acid deposition. In the partially acidified St. Mary’s River, fry and older parr densities remained among the lowest of record (1985-2006). Trends in densities of age-1+ and older parr in the outer Bay of Fundy (SFA 23) have varied since 1980, with densities in the Nashwaak River and Saint John River above Mactaquac Dam declining in response to reduced spawning escapements. For the salmon stock in 33 rivers of the inner Bay of Fundy (SFA 22 and a portion of SFA 23), juvenile densities remained critically low.

## USA

Wild salmon smolt production has been estimated on the Narraguagus River for nine years (Figure 4.9.7.1). Smolt production in 2006 was higher than 2005 and $22 \%$ higher than the previous five-year mean production. The mean juvenile densities in this river have been low over the period of sampling dating to 1997.

### 4.9.7.2 Estimates of total adult abundance by geographic area

Returns of 1SW and 2SW salmon to each region (Tables 4.9.7.1 and 4.9.7.2; Figures 4.9.7.2 and 4.9.7.3; and Annex 5) were estimated by the methods and variables reported by Rago et al. (1993b) and reported in ICES (1993). The returns for both sea-age groups were derived by applying a variety of methods to data available for individual river systems and management areas. These methods included counts of salmon at monitoring facilities, population estimates from mark-recapture studies, and the application of angling and commercial catch statistics, angling exploitation rates, and measurements of freshwater habitat. The 2SW component of the MSW returns was determined using the sea-age composition of one or more indicator stocks.

Returns are the number of salmon that returned to the geographic region, including fish caught by homewater commercial fisheries, except in the case of the Newfoundland and Labrador regions where returns do not include landings in commercial and food fisheries. This avoided double counting fish because commercial catches in Newfoundland and Labrador and food fisheries in Labrador were added to returns to create the PFA of North American salmon. The basis for estimates of 2SW and 1SW salmon returns and spawners for Labrador (SFAs 1, 2 \& 14B) prior to 1998 are catch data from angling and commercial fisheries. In 1998, the commercial fishery in Labrador was closed and the model for returns and spawners from commercial catch data could not be used. From 2002-2006, there were counting projects on four salmon rivers in Labrador. Because the same four out of about 100 rivers (one in SFA 1A, Northern Labrador and three in SFA 2) were monitored, the Working Group extrapolated from return rates per accessible drainage areas to the unsurveyed rivers in Labrador (ICES 2005).

Estimates of 1SW and 2SW returns and spawners for Newfoundland (SFAs 3-12 \& 14A) were previously documented based on the classification scheme of the Salmon Management Plan. Returns and spawners were updated for 2005 and new estimates were provided for 2006 based on catches, calculated exploitation rates and large to small salmon ratios from the Licence Stub Return System in 2006. It has been noticed in the last couple of years that angling catches when completed in the year following the current estimate year increase and exploitation rates decrease leading to a reduction in return and spawner estimates compared to those reported the previous year. Consequently, the current year estimate may be overestimated.

Prior to closures of fisheries in 1985 returns of salmon to SFA 19 to 21 could be estimated by sums of catches and counts across fisheries. Since 1985, returns to SFA 19 to 21 were based on a significant relationship between catch in these SFAs and an index river, LaHave River, where counts have been made in a fishway trap since 1972.

Total returns of salmon to USA rivers are the sum of trap catches and redd based estimates.
Returns do not include aquaculture escapes in rivers where removal is possible. In the Magaguadavic River (SFA 23) 6 fish farm escapees were removed in 2006. Aquaculture escapes were also intercepted on the St. Croix (7), Dennys (4), and Penobscot (1) rivers.

## Canada

## Labrador

The mid-point of the estimated returns (214 051) of 1SW salmon to Labrador rivers in 2006 is $3 \%$ lower than in 2005 and is the 2sd highest recorded (Figure 4.9.7.2, Annex 5). The midpoint (14000) of the estimated 2SW returns to Labrador rivers in 2006 was $2 \%$ higher than in 2005 and $1 \%$ lower than the recent $5-$ year average of 13820 (Figure 4.9.7.3).

## Newfoundland

The mid-point of the estimated returns (225 154) of 1SW salmon to Newfoundland rivers in 2006 is $19 \%$ higher than the average 1SW returns (189 150) for the past five years (Figure 4.9.7.2). The mid-point (4542) of the estimated 2SW returns to Newfoundland rivers in 2006 was $26 \%$ higher than in 2005 and $13 \%$ higher than the recent 5 -year average of 4029 (Figure 4.9.7.3).

## Québec

The mid-point of the estimated returns to Québec in 2006 of 1SW salmon (29 844) is 19\% above that observed in 2005 but unchanged from the previous five-year mean (Figure 4.9.7.2). The mid-point of the estimated returns of 2SW (28 808) salmon is similar ( $-9 \%$ ) to that observed for 2005 and the previous 5-year average (-12\%) (Figure 4.9.7.3).

## Gulf of St. Lawrence, SFAs 15-18

The mid-point ( 53238 ) of the estimated returns in 2006 of 1 SW salmon to the Gulf of St. Lawrence was $23 \%$ higher than 2005 and unchanged from the previous five year mean return. The values noted in 1997 through 2006 are low relative to the values observed during 19851993 (Figure 4.9.7.2). The mid-point (25 275) of the estimate of 2SW returns in 2006 is unchanged from the estimate for 2005 but $11 \%$ above the previous 5 -year average return (Figure 4.9.7.3).

## Scotia-Fundy, SFAs 19-23

The mid-point (9331) of the estimate of the 1SW returns in 2006 to the Scotia-Fundy Region was a $34 \%$ increase from the 2005 estimate, and the sixth lowest value in the time-series, 1971-2006. Returns have generally been low since 1990 (Figure 4.9.7.2). Six of the seven lowest values have occurred since 2000. The mid-point (2682) of the 2SW returns in 2005 is $58 \%$ higher than the returns in 2005 but is still low in relation to the 1971-2006 time series (Figure 4.9.7.3). A declining trend in returns has been observed from 1985 to 2006, despite this recent single year increase.

## USA

Total returns of salmon to USA rivers was 1480, a 13\% increase from returns in 2005 (1313). Total salmon returns to the rivers of New England remain below the long term average of 2122 (1967-2002). The 2006 level is above the 10 -year average and below the 5 -year average (Figure 4.9.7.2). Returns of 1 SW salmon were 450, greater than the 5 -year (306) and 10-year
(342) averages. The 2SW returns in 2006 to USA rivers were 1030 fish, an increase over the $5-$ year average (856) but not the $10-$ year (1148) average (Figure 4.9.7.3).

### 4.9.7.3 Estimates of spawning escapements

Updated estimates for 1SW spawners were derived for the six geographic regions (Table 4.9.7.3). Estimates of 2SW spawners, 1971-2006 are provided in Table 4.9.7.4. These estimates were calculated by subtracting the in-river removals from the estimates of returns to rivers and/or adding stocked spawners. A comparison between the numbers of spawners, returns, and CLs for 2SW salmon (Figure 4.9.7.3 ).

## Canada

## Labrador

Spawner estimates for Labrador in 1998-2006 were developed, using the monitoring facilities for 2002-2006 and the proportional method for 1998-2001 (Section 4.9.5). The mid-point of the estimated numbers of 2SW spawners (13791) was $2 \%$ below the previous year and was $40 \%$ of the total 2SW CL for Labrador (Figure 4.9.7.3). The 2SW spawner limit has only been exceeded once (1998) since 1971. The mid-point of the estimated numbers of 1SW spawners (211 972) was 3\% lower that estimated for 2005 (Figure 4.9.7.2).

## Newfoundland

The mid-point of the estimated numbers of 2SW spawners (4491) in 2006 was $27 \%$ above that estimated in 2005 (3540) and was 112\% of the total 2SW CL for all rivers. The 2SW spawner limit has been met or exceeded at the mid-point of spawner estimates in eight years out of the last ten (Figure 4.9.7.3). The 1SW spawner abundance (205 489) in 2006 was $24 \%$ higher than in 2005 (199 153). The abundance of 1SW spawners in 1992 was higher than in 1989-1991 and similar to levels in the late 1970s and 1980s (Figure 4.9.7.2), although in 1995-1996 it was unusually high. There was a general increase in both 2 SW and 1SW spawners during the period 1992-96 and 1998-2000, which is consistent with the closure of the commercial fisheries in Newfoundland.

## Québec

The mid-point of the estimated numbers of 2SW spawners (19070) in 2006 was unchanged ( $<10 \%$ ) relative to 2005, to the previous five year mean, and was about $65 \%$ of the sum of the 2SW CL for all rivers (Figure 4.9.7.3). The mid-point of the estimated 1SW spawner abundance in 2006 (21660) was about 18\% higher than in 2005 (Figure 4.9.7.2) and approximates the 10 year average.

## Gulf of St. Lawrence

The mid-point of the estimated numbers of 2SW spawners (24639) in 2006 was unchanged ( $<10 \%$ ) relative to 2005 , up by $11 \%$ relative to the previous five year mean, and was about 81\% of the total 2SW CL for the region (Figure 4.9.7.3). This area has not met the combined 2SW CL since 1996. The mid-point of the estimated spawning escapement of 1SW salmon ( 34900 ) increased by $22 \%$ from 2005 and was $13 \%$ above the average for the last ten year (Figure 4.9.7.2).

## Scotia-Fundy

The mid-point of the estimated numbers of 2SW spawners (2546) in 2006 is a $58 \%$ increase from 2005 and is about $10 \%$ of the total 2SW CLs for rivers in this region (Figure 4.9.7.3). Neither the spawner estimates nor the CLs include rivers of the inner Bay of Fundy (SFA 22 and part of SFA 23) as these rivers are minor contributors to distant water fisheries and spawning escapements are extremely low. The 2 SW spawning escapement in the rest of the
area has been generally declining since 1985. The mid-point of the estimated 1SW spawners (9114) in 2006 is a $34 \%$ increase from 2005 (Figure 4.9.7.2).

## USA

Pre-spawning adults were stocked into USA rivers, however, even with these, all age classes of spawners (1SW, 2SW, 3SW, and repeat) in 2006 (1876 salmon) represented $6.4 \%$ of the 2SW spawner requirements for all USA rivers combined.

### 4.9.7.4 Reconstructed spawning escapements

Lagged spawners for North America were derived following the technique outlined in ICES (2005). Spawners in each geographic area were allocated (weighted forward) to the year of the non-maturing 1SW component in the Northwest Atlantic using the weighted smolt age proportions from each area (Table 4.9.7.5). The original USA smolt age distributions are used to allocate the USA spawners for years 1971-1989 and the new distribution for 1990 onward. Changes were made to the USA portion of the table due to declines in natural spawning for USA Atlantic salmon populations and changes in hatchery and stocking practices. The total spawners for a given recruitment year in each area is the sum of the lagged spawners. Because the smolt age distributions in North America range from one to six years and the time-series of estimated 2SW spawners to North America begins in 1971, the first recruiting year for which the total spawning stock size can be estimated is 1979 (although a value for 1978 was obtained by leaving out the 6 -year old smolt contribution which represents $4 \%$ of the Labrador stock complex).

Spawning escapement of 2SW salmon to several stock complexes has been below CLs (Labrador, Québec, Scotia-Fundy, USA) since the 1980s (Table 4.9.7.3). Lagged 2SW spawner abundance has decreased in Labrador and Newfoundland over the past five years, has remained steady in Québec, declining and very low in Scotia Fundy and decreased for 2007 in the Gulf from the previous year (Figure 4.9.7.4).

The relative contributions of the stocks from these six geographic areas to the total spawning escapement of 2SW salmon has varied over time (Table 4.9.7.6, Figure 4.9.7.5). The reduced potential contribution of Scotia-Fundy stocks and the initial increased proportion of the spawning stock from the Gulf of St. Lawrence and, more recently, from Labrador rivers to future recruitment is most noticeable.

### 4.9.8 Egg depositions in 2006

Egg depositions by all sea-ages combined in 2006 exceeded or equalled the river specific CLs in 35 of the 77 assessed rivers (45\%) and were less than $50 \%$ of CLs in 27 other rivers (35\%) (Figure 4.9.8.1).

- In Newfoundland, $63 \%$ of the rivers assessed met or exceeded the CLs and 4\% had egg depositions that were less than $50 \%$ of limits.
- Due to high water conditions 6 of 7 rivers in St. George Bay in southwest Newfoundland (SFA 13) where 2SW salmon are more prominent in the populations could not be assessed in 2006.
- None of the four assessed rivers in Gulf and 6 of the 35 assessed rivers in Québec had egg depositions less than 50\% of CLs.
- For 3 of 4 of the Gulf rivers and $54 \%$ of the Québec rivers, egg depositions equalled or exceeded CLs.
- Large deficiencies in egg depositions were noted in the Bay of Fundy and Atlantic coast of Nova Scotia (SFA 19-23) where 11 of the 13 rivers assessed (85\%) had egg depositions that were less than $50 \%$ of CLs.
- Large deficiencies in egg depositions were noted in the USA, where only one of the rivers assessed had egg depositions that were greater than $10 \%$ of CLs. On an individual river basis, the Penobscot River met $10 \%$ of its spawner requirement while all the other USA rivers were between $0.0-1.0 \%$ of their 2 SW requirements

### 4.9.9 Marine survival rates

In 2006, return rate data were available from 10 wild and five hatchery populations from rivers distributed among Newfoundland, Québec, Scotia-Fundy and USA (Figure 4.9.9.1). Return rates to 1SW fish in 2006 increased by >10\% relative to 2005 for three hatchery stocks ( $+25 \%$ to $+44 \%$ ) and in seven of the wild stocks ( $+25 \%$ to $+600 \%$ ) but decreased in three wild stocks ( $-20 \%$ to $-46 \%$ ).

Return rates to 2 SW salmon from the 2004 smolt class increased relative to the 2003 smolt class for only one wild stock ( $+270 \%$ ) and four hatchery stocks ( $+22 \%$ to $671 \%$ ) while rates declined in three wild stocks ( $-1 \%$ to $-21 \%$ ) and in one hatchery stock ( $-4 \%$ ).

These time series of return rates of smolts to 1SW and 2SW adults (Figure 4.9.9.1) and analysis of exponential rates of change (Figures 4.9.9.2) provide insights into temporal changes in marine survival of wild and hatchery stocks:

- Return rates of fish to many rivers are low compared to historical levels, especially in the south.
- Return rates of fish to home waters did not increase as expected after closure of the commercial fisheries in 1984 and subsequently in 1992,
- 1SW return rates in MSW salmon stocks (USA, Scotia-Fundy, Gulf, Quebec) are lower than those in predominantly 1SW salmon stocks of Newfoundland,
- $\quad 1$ SW return rates in MSW salmon stocks of the Scotia-Fundy and Gulf exceed those of 2 SW salmon but 2SW returns rates are greater than 1SW return rates in Québec and Maine populations, and
- Return rates of wild stocks exceed those of hatchery stocks.

| SUMMARY OF RETURN RATES OF MONITORED STOCKS FOR THE LAST FIVE YEARS |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Origin | Age <br> Group | Region | Return rate |  | Number Of stocks |
|  |  |  | Mean (\%) | Range (\%) |  |
| Wild | 1SW | Maine (USA) | 0.14 | 0.08 to 0.24 | 1 |
|  |  | Scotia-Fundy | 4.47 | 1.13 to 12.73 | 2 |
|  |  | Gulf | 4.20 | 1.90 to 6.40 | 2 |
|  |  | Québec | 0.73 | 0.36 to 1.49 | 2 |
|  |  | Newfoundland | 6.08 | 2.20 to 15.10 | 5 |
| Wild | 2SW | Maine (USA) | 0.68 | 0.15 to 0.94 | 1 |
|  |  | Scotia-Fundy | 0.77 | 0.23 to 1.58 | 2 |
|  |  | Gulf | 1.08 | 0.30 to 2.20 | 2 |
|  |  | Québec | 0.71 | 0.12 to 1.39 | 2 |
| Hatchery | 1SW | USA | 0.04 | $\begin{gathered} 0.015 \text { to } \\ 0.067 \end{gathered}$ | 3 |
|  |  | Scotia-Fundy | 0.54 | 0.32 to 0.87 | 2 |
| Hatchery | 2SW | USA | 0.10 | $\begin{gathered} 0.004 \text { to } \\ 0.261 \end{gathered}$ | 3 |
|  |  | Scotia-Fundy | 0.10 | 0.05 to 0.17 | 2 |

### 4.9.10 Pre-fisheries abundance

### 4.9.10.1 North American run-reconstruction model

The Working Group has used the "North American Run-Reconstruction Model" to estimate pre-fishery abundance, which serves as the basis of abundance forecasts used in the provision of catch advice. The catch statistics used to derive returns and spawner estimates have been updated from those used in ICES (2005, Table 4.9.10.1). The North American RunReconstruction Model has also been used to estimate the fishery exploitation rates for West Greenland and in home waters.

### 4.9.10.2 Non-maturing 1 SW salmon

The non-maturing component of 1SW fish, destined to be 2SW returns (excludes 3SW and previous spawners) is represented by the pre-fishery abundance estimator for year i designated as [NN1(i)]. This annual pre-fishery abundance is the estimated number of salmon in West Greenland prior to the start of the fishery on August 1st. Definitions of the variables are given in Table 4.9.10.2. It is constructed by summing 2SW returns in year $\mathrm{i}+1$ [NR2(i+1)], 2SW salmon catches in commercial and Aboriginal peoples’ food fisheries in Canada [NC2(i+1)], and catches in year i from fisheries on non-maturing 1SW salmon in Canada [NC1(i)] and Greenland [NG1(i)] (Table 4.9.10.3). In Labrador, Aboriginal peoples' food harvests of small (AH_s) and large salmon (AH_l) were included in the reported catches for 1999-2006 (Table 4.9.10.1). Because harvests occurred in both Lake Melville and coastal areas of northern Labrador, the fraction of these catches that are immature was labelled as af_imm. This was necessary because non-maturing salmon do not occur in Lake Melville where much of the catch originated. However, non-maturing salmon may occur in marine areas in the remainder of northern Labrador. Consequently, af_imm for the fraction of Aboriginal peoples’ harvests that was non-maturing was set at 0.05 to 0.1 which is half of f _imm from commercial fishery samples. The full details and equations for calculating prefishery abundance are in ICES (2004). The model does not take into account non-catch fishing mortality in any of the fisheries. The West Greenland (1993 and 1994), Newfoundland (1992-2006), and Labrador commercial fishery (1998-2006), were closed in these years.

As the pre-fishery abundance estimates for potential 2SW salmon requires estimates of returns to rivers, the most recent year for which an estimate of PFA is available is 2005. This is because pre-fishery abundance estimates for 2006 require 2 SW returns to rivers in North America in 2007. The minimum and maximum values of the catches and returns for the 2SW cohort are summarized in Table 4.9.10.3. The 2005 abundance estimates ranged between 75095 and 145408 salmon. The mid-point of this range (110 251) is similar to the 2004 value (109 813) and is the $5^{\text {th }}$ lowest in the 34 -year time-series (Figure 4.9.10.1). Even though the 2005 value has increased somewhat from 2001, which was the lowest in the time series, the general trend towards lower values in recent years is still evident and current year values are still much lower than the 917282 in 1975.

### 4.9.10.3 Maturing 1 SW salmon

Maturing 1SW salmon are in some areas a major component of salmon stocks, and their abundance provides an index of the entire smolt cohort.

For the commercial catches in Newfoundland and Labrador, all small salmon are assumed to be 1SW fish based on catch samples which show the percentage of 1SW salmon to be in excess of $95 \%$. Large salmon are primarily MSW salmon, but some maturing and nonmaturing 1SW are also present in commercial catches in SFAs 1-7, and 14B. Estimates of fractions of non-maturing salmon present in the Newfoundland and Labrador catch were presented in ICES (1991). The large category in SFAs $1-7$ and 14B consists of $0.1-0.3$ 1SW salmon (Rago et al., 1993a; ICES, 1993). Salmon catches in SFAs 8-14A are mainly maturing
salmon (Idler et al., 1981). These values were assumed to apply to the Aboriginal food fishery catches in marine coastal areas of northern Labrador. Catches used in the run-reconstruction model for the Newfoundland commercial fishery were set to zero for 1992-2006 and for Labrador for 1998-2006 to remain consistent with catches used in other years in these areas. Full details on the method used to calculate the numbers of maturing 1SW salmon are in ICES (2004).

The minimum and maximum values of the catches and returns for the 1 SW cohort are summarized in Table 4.9.10.4. The mid-point values of the reconstructed abundance of the 1SW maturing cohort are shown in Figure 4.9.10.1. The mid-point of the range of pre-fishery abundance estimates for 2006 (557 364) is $2 \%$ higher than in 2005 (546 364), had increased considerably from the value of 309015 in 1994, which was the lowest estimated in the timeseries 1971-2006.

### 4.9.10.4 Total 1 SW recruits (maturing and non-maturing)

The pre-fishery abundance of 1SW maturing salmon for the 1971-2006 and 1SW nonmaturing salmon from North America for 1971-2005 were combined to give total recruits (Figure 4.9.10.2). While maturing 1SW salmon in 1998-2006 have increased over the lowest value in 1994, the non-maturing portion of these cohorts remains basically unchanged since 1997. The prefishery abundance of the non-maturing portion (potential 2SW salmon) has been consistently well below the Spawning Escapement Reserve (derived from the CL) since 1993. The maturing component has declined by $47 \%$ the non maturing has declined by $92 \%$.

### 4.9.10.5 Forecast models for pre-fishery abundance of 2SW salmon

A two-phase regression between pre-fishery abundance (PFANA) and lagged spawners (LSNA) as described by Chaput et al. (2005) was updated with the addition of the previous years $\mathrm{PFA}_{\mathrm{NA}}$ estimate. The relative recruits $\left(\mathrm{PFA}_{\mathrm{NA}}\right)$ per spawner index $\left(\mathrm{LS}_{\mathrm{NA}}\right)$ has declined from an average of 5.7 during 1978-1989 to an average of 1.9 during the period 1990 to 2005 (Figure 4.9.10.3). As in 2006, a number of models were examined including two models without phase shifts, plus five models with phase shifts and with eight possible break year points (1986-1993) for each model (Table 4.9.10.5). In each simulation the most parsimonious model was selected using Akaike's Information Criterion and this selected model was used to generate a value for the probability density for the $2007 \mathrm{PFA}_{\mathrm{NA}}$. Simulation methods, in the software package SAS (SAS Institute, 1996), were used to generate the probability density function of $\mathrm{PFA}_{\mathrm{NA}}$ (Annex 6).

For phase shift models, the probability of being in either phase was based on changes in $\mathrm{PFA}_{\mathrm{NA}}$ from year t relative to year t -2 (Figure 4.9.10.4). The two-year lag is used because current year PFA (i.e 2006) is not available due to its dependence upon 2SW returns in the next year. The approach taken in 2007 was identical to the method used in previous years and as described by Chaput et al. (2005).

Although 42 combinations of models and break years (8 years * 5 regressions +2 regressions without break years) were possible that could be represented in estimating the distribution of $\mathrm{PFA}_{\mathrm{NA}}$, those selected most often were model numbers 2 and 6 and break years 1988 through 1992 (Table 4.9.10.6). The lagged spawner variable was informative for $\mathrm{PFA}_{\mathrm{NA}}$ in $70 \%$ of the simulated data sets. In such cases, the break years describing the phase shift were mostly 1991 or 1989 and to lesser extents 1988 and 1992. The proportional model with the intercept through the origin was selected most often ( $62 \%$ of all models). For the 2007 forecast of $\mathrm{PFA}_{\mathrm{NA}}$, the probability (runs/10000) of being in the high phase was low (2.5\%) and the probability of being in the lower productivity phase was over $97 \%$ (Table 4.9.10.6).

The $\mathrm{PFA}_{\mathrm{NA}}$ abundance during 2007 to 2009 is expected to be about 115000 non-maturing 1SW salmon (Table 4.9.10.7), a value similar to the estimated abundance for the period 1988
to 2005. The $\mathrm{PFA}_{N A}$ values over the most recent 15 year period (1991-2005) have declined by $64 \%$ (Figure 4.9.10.2). Between 1971 and 2005, the PFA $_{\text {NA }}$ abundance has declined by $92 \%$.

### 4.9.11 Summary on status of stocks

In 2006, the midpoint of the spawner abundance estimates for six geographic areas indicated that five areas were below their CL for 2 SW salmon and are suffering reduced reproductive capacity. Newfoundland was at or slightly above CL.

Estimates of pre-fishery abundance suggest continued low abundance of North American adult salmon. The total population of 1SW and 2SW Atlantic salmon in the northwest Atlantic has oscillated around a generally declining trend since the 1970s. During 1993 to 2005, the total population of 1 SW and 2SW Atlantic salmon was about 600000 fish, about half of the average abundance during 1972 to 1990. The maturing component has declined by $47 \%$ the non maturing has declined by $92 \%$.

The returns of 2SW fish in 2006 were similar to 2005 in Labrador, in the Gulf of St. Lawrence, Scotia Fundy and in the USA, increased slightly in Newfoundland, but declined slightly in Québec. However, in all areas returns remain close to the lower end of the 35-year time-series (1971-2005). While 2SW salmon are a minor component of Newfoundland stocks even here decreases of about $30 \%$ have occurred from peak levels of the 1990's. Returns in 2006 of 1SW salmon increased from 2005 in Newfoundland and Labrador but declined or were similar in all other areas.

The rank of the estimated returns in the 1971-2006 time-series and the proportions of the 2SW CL achieved in 2006 for six regions in North America are shown below:

| REGION | RANK OF 2006 RETURNS IN <br> 1971-2006, (36=LOWEST) | RANK OF 2006 RETURNS IN <br> 1997-2006 (10=LOWEST) | MID-POINT ESTIMATE OF 2SW <br> SPAWNERS AS PERCENTAGE OF <br> CONSERVATION LIMIT ( $\mathbf{S H M}_{\text {LIM }}$ |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{1 S W}$ | 2SW | $\mathbf{1 S W}$ | $\mathbf{2 S W}$ | (\%) |
| Labrador | 2 | 20 | 2 | 6 | 40 |
| Newfoundland | 4 | 19 | 1 | 6 | 112 |
| Québec | 16 | 35 | 4 | 3 | 65 |
| Gulf | 24 | 27 | 3 | 9 | 81 |
| Scotia-Fundy | 30 | 32 | 4 | 6 | 10 |
| USA | 12 | 31 | 1 | 7 | 5 |

Egg depositions by all sea-ages combined in 2006 exceeded or equalled the river specific CLs in 35 of the 77 assessed rivers (45\%) and were less than $50 \%$ of CLs in 27 other rivers ( $35 \%$, Figure 4.9.8.1).

Return rates to 1 SW and 2 SW salmon remain variable and unpredictable with higher return rates in the northern areas (Newfoundland) and lower rates in the southern areas, including southern Newfoundland, Maritimes and USA.

Based on the genera1 increase in 1SW returns in 2006 in all areas except Labrador an increase could be expected for 2 SW salmon in 2007 . However, return rates of 2 SW salmon in monitored stocks remain low. An additional concern is the number of salmon stocks suffering reduced reproductive capacity in eastern NAC, particularly in the Bay of Fundy, Atlantic coast and USA Despite major changes in fisheries management, returns have continued to decline in these southern areas and many populations are currently threatened with extirpation.

### 4.10 NASCO has requested ICES to evaluate the extent to which the objectives of any significant management measures introduced in recent years have been achieved

There have been no significant management measures introduced within the NAC in recent years.

Table 4.9.1.1. Catches expressed as 2SW salmon equivalents in North American salmon fisheries, 1972-2006, based on the mid-points of the estimated values.

Labrador: SFAs 1,2\&14B
Newfoundland: SFAs 3-14A
Gulf of St. Lawrence: SFAs 15-18
Scotia-Fundy: SFAs 19-23 (SFA 22 is not included as it does not produce 2SW salmon)
Quebec: Q1-Q11

Labrador : SFAs $1,2 \& 14 B$
Newfoundland: SFAs 3-14A
Gulf of St. Lawrence: SFAs 15-18
Scotia-Fundy: SFAs 19-23 (SFA 22 is not included as it does not produce 2SW salmon)
Quebec: Q1-Q11

Table 4.9.7.3. Estimated numbers of 1SW spawners in North America by geographic regions, 1971-2006.

|  | Labrador |  | Newfoundland |  | Quebec |  | Gulf of St. Lawrence |  | Scotia-Fundy |  | USA | North America |  |  |

AH_s

S2
MN1(i)
RFL1
RFL2
t1 Time between the mid-point of the Canadian fishery and return to river $=$ 1 months

AH_l Aboriginal and resident food harvest of large salmon in northern Labrador
f_imm Fraction of 1SW salmon that are immature, i.e. non-maturing: range = 0.1 to 0.2
af_imm Fraction of 1SW salmon that are immature in native and resident food fisheries in N Lab
q Fraction of 1SW salmon present in the large size market category; range $=0.1$ to 0.3

MC1(i) Harvest of maturing 1SW salmon in Newfoundland and Labrador in year i
i+1 Year of fishery on 2SW salmon in Canada
MR1(i) Return estimates of maturing 1SW salmon in Atlantic Canada in year i
NN1(i) Pre-fishery abundance of non-maturing 1SW + maturing 2SW salmon in year i
NR(i) Return estimates of non-maturing + maturing 2SW salmon in year i
NR2(i+1) Return estimates of maturing 2SW salmon in Canada
NC1(i) Harvest of non-maturing 1SW salmon in Nfld + Labrador in year i
NC2(i+1) Harvest of maturing 2SW salmon in Canada
NG(i) Catch of 1SW North American origin salmon at Greenland
Year of the fishery on 1SW salmon in Greenland and Canada
Natural mortality rate ( 0.03 per month)

Survival of 1SW salmon between the homewater fishery and return to river $\{\exp (-\mathrm{M} t 1)\}$
Number of "Small" salmon caught in Canada in year i; fish <2.7 kg
Number of "Large" salmon caught in Canada in year i; fish >=2.7 kg
Aboriginal and resident food harvests of small salmon in northern Labrador I

Survival of 2SW salmon between Greenland and homewater fisheries
Pre-fishery abundance of maturing 1SW salmon in year i
Labrador raising factor for 1SW used to adjust pre-fishery abundance
Labrador raising factor for 2SW used to adjust pre-fishery abundance

Figure 4.9.7.1. Time series of wild smolt production from sixteen monitored rivers in eastern Canada and one river of eastern USA, 1971-2006. Smolt production is expressed relative to the conservation egg requirements of the rivers.

Figure 4.9.7.2. Comparison of estimated mid-points of 1 SW returns to and 1 SW spawners in rivers of six geographic areas in North America. Returns and spawners for Scotia-Fundy do not include those from SFA 22 and a portion of SFA 23. Note scale differences for USA.

Figure 4.9.7.3. Comparison of estimated mid-points of 2 SW returns, 2SW spawners, and 2SW conservation requirements for six geographic areas in North America. Returns and spawners for Scotia-Fundy do not include those from SFA 22 and a portion of SFA 23.

Figure 4.9.7.4. Midpoints of lagged spawners (solid circles) and estimated annual spawners (open circles) as contribution to potential recruitment in the year of prefishery abundance (PFA) for six geographic areas of North America. The horizontal line represents the spawning requirement (in terms of 2SW fish) in each geographic area.

Figure 4.9.7.5. Proportion of spawners (mid-points) lagged to year of PFA (solid circles) and as returns to rivers (open circles) in six geographic areas of North America relative to the total lagged spawner or annual spawning escapement to North America. The horizontal line represents the theoretical spawner proportions for each area based on the 2SW spawner requirement for North America.

Figure 4.9.8.1. Proportion of the conservation requirement attained in assessed rivers of the North American Commission in 2006.

Figure 4.9.9.1. Standardized mean (one standard error bars) annual return rates of wild and hatchery origin smolts to 1 SW and 2 SW salmon to the geographic areas of North America The standardized values are annual means derived from a general linear model analysis of rivers in a region. Survival rates were log transformed prior to analysis.

Figure 4.9.9.2. Annual rate of change (\%) of return rates to 1 SW and 2SW salmon by wild (left) and hatchery (right) salmon smolts to rivers of eastern North America. Black circles are for 1SW and open circles are for $2 S W$ data series.

Figure 4.9.10.1. Prefishery abundance estimate of maturing and non-maturing salmon in North America. Open symbols are for the years that returns to Labrador were assumed as a proportion of returns to other areas in North America and the grey symbols for deriving returns to Labrador using returns per unit of drainage area.

Figure 4.9.10.2. Total 1SW recruits (non-maturing and maturing) originating in North America.

Figure 4.9.10.3. PFA estimates (mid-point, minimum and maximum range; top left), lagged spawners for North America (mid-point, minimum and maximum range; top right), PFA to lagged spawner association for the NAC area showing the sequence from 1978 to 2005 (middle panel), recruitment rate (mid-point, minimum, maximum ratios of PFA to LS; bottom left) and the change of the PFA in year relative to year-2 (bottom right panel).

Figure 4.9.10.4. Run reconstruction estimates (grey bullets) of PFA NA and forecast estimate distributions (white squares) for the years 2006 to 2009 non-maturing 1SW salmon. Error bars are minimum and maximum range for reconstructed values, $5^{\text {th }}$ to $95^{\text {th }}$ percentile ranges for the forecast values. Trend line is the exponential change in PFA for the most recent 15 years.

## 5 Atlantic salmon in the West Greenland Commission

### 5.1 Status of stocks/exploitation

The Working Group considers the stock complex at West Greenland to be below conservation limits and thus suffering reduced reproductive capacity.

In European and North American areas, the overall status of stocks contributing to the West Greenland fishery is among the lowest recorded, and as a result, the abundance of salmon within the West Greenland area is thought to be extremely low compared to historical levels. Status of stocks in the NEAC and NAC areas are presented in the relevant commission sections (Sections 3 and 4).

The Working Group noted that an exploitation rate for North American non-maturing 1SW fish at West Greenland can be calculated by dividing the recorded harvest of 1SW salmon at West Greenland by the PFA estimate for the corresponding year for North American salmon. These exploitation rates in the last four years have averaged around 3\% (Figure 5.1.1).

### 5.2 Management objectives

For management advice for the West Greenland fishery, NASCO has adopted a precautionary management plan requiring at least a $75 \%$ probability of achieving three management objectives:

- Meeting the conservation limits simultaneously in the four northern regions of North America: Labrador, Newfoundland, Quebec, and Gulf.
- For the two southern regions in North America, Scotia-Fundy and USA, where there is a zero chance of meeting conservation limits: achieve increases in returns relative to previous years with the hope of rebuilding the stocks. In 2004, ICES established 1992-1996 as the range of years to define the baseline for the ScotiaFundy and USA regions to assess $\mathrm{PFA}_{\mathrm{NA}}$ abundance and fishery options. Improvements of greater than $10 \%$ and greater than $25 \%$ relative to returns during this base period are evaluated. The $25 \%$ increase is the limiting factor because if it is achieved, by definition the $10 \%$ increase is also achieved.
- Meeting the conservation limit for the Southern NEAC MSW complex.

Although not a formal management objective, ICES also provides the probability of returns to North America being equal or less than the previous five-year average. USA returns relative to returns during 1992-1996 to carry forward in catch options.

### 5.3 Reference points

The reference points for West Greenland catch options are the conservation limits (CLs) for North American and Southern European stock complex. NASCO has adopted region specific CLs (NASCO, 1998). In many regions of North America, the CLs are calculated as the number of spawners required to fully seed the wetted area of the river. In some regions of Europe, pseudo stock-recruitment observations are used to calculate a hockey stick relationship, with the inflection point defining the CLs. In the remaining regions, the CLs are calculated as the number of spawners that will achieve long-term average maximum sustainable yield (MSY), as derived from the adult-to-adult stock and recruitment relationship (Ricker, 1975; ICES, 1993). These regional CLs are limit reference points; having populations fall below these limits should be avoided with high probability.

CLs for the West Greenland fishery for North America are limited to 2SW salmon and southern European stocks are limited to MSW fish because fish at West Greenland are primarily (> 90\%) 1SW non-maturing salmon destined to mature as either 2SW or 3SW salmon. The 2SW spawner limits of salmon stocks from North America total 152548 fish,
with 123349 required in Canadian rivers and 29199 in USA rivers (see Section 4.3). The current CL estimate for Southern European MSW stocks is approximately 269000 fish (Section 3.3.2). There is still considerable uncertainty in the CLs for European stocks and estimates may change from year to year as the input of new data affects the pseudo-stockrecruitment relationship.

Spawner escapement reserve (SER) is the number of salmon at West Greenland required to ensure that returns to a region the following year achieve region-specific conservation requirements. To calculate SER, expected losses from natural mortality over the migration time from West Greenland to home rivers ( 8 months for Southern Europe and 11 months for North America) are added to regional CLs (Table 5.3.1).

### 5.4 Management advice

The Working Group followed the process developed last year for providing management advice and catch options for West Greenland using the PFA and CLs of the NAC and NEAC areas. The risks of the Greenland fishery to NAC and NEAC stock complexes are developed in parallel and combined into a single catch option table.

### 5.4.1 Catch options for West Greenland

None of the stated management objectives would allow a fishery at West Greenland to take place in 2007, 2008, or 2009.

In the absence of any marine fishing mortality, there is a very low probability ( $<3 \%$ ) that the returns of 2SW salmon to North America in 2008, 2009, and 2010 will be sufficient to meet the conservation requirements of the four northern regions (Labrador, Newfoundland, Quebec, and Gulf) (Table 5.4.1). There is essentially no chance ( $<1 \%$ ) that the returns in the southern regions (Scotia-Fundy and USA) will be greater than the returns observed in the 1992-1996 base period in any of the three years. Lastly, in the absence of a fishery, the probability that returns in all regions of North America will be decline further from the average of the period 2002 to 2006 is $36 \%$ for 2008 , $30 \%$ for 2009, and $34 \%$ for 2010 (Table 5.4.2).

In the absence of any fisheries, there is only a $64 \%$ chance that the MSW CL for southern Europe will be met in 2008 (Table 5.4.1). For 2009 and 2010, the probability that the MSW returns for southern Europe will meet or exceed the CL in the absence of fisheries declines to $56 \%$ and $47 \%$, respectively (Tables 5.4.1).

### 5.5 Relevant factors to be considered in management

At its annual meeting in June 2005 NASCO agreed to restrict the fishery at West Greenland to that amount used for internal subsistence consumption in Greenland. Consequently, the Greenlandic authorities set the commercial quota to nil, i.e. landings to fish plants, resale in grocery shops/markets, and commercial export of salmon from Greenland was forbidden. Licensed fishermen were allowed to sell salmon at the open markets, to hotels, restaurants, and institutions. A private fishery for personal consumption without a license was allowed. All catches, licensed and private were to be reported to the License Office on a daily basis. In agreement with the Organization for Fishermen and Hunters in Greenland the fishery for salmon was allowed from August 1 to October 31.

The salmon caught in the West Greenland fishery are mostly (>90\%) non-maturing 1SW salmon, most of which are destined to return to home waters in Europe or North America as 2SW fish. The primary MSW European stocks contributing to the fishery in West Greenland are thought to originate from the southern stock complex, although low numbers may originate from other stock complexes. Most MSW stocks in North America are thought to
contribute to the fishery at West Greenland. Previous spawners, including salmon that spawned first as 1 SW and 2 SW salmon also contribute to the fishery.

### 5.6 Prefishery abundance forecasts 2007, 2008, 2009

The PFA forecasts for the West Greenland stock complex are among the lowest in time series (Figure 5.6.1).

### 5.6.1 North American stock complex

The Working Group has described two temporal phases (ICES 2003) of salmon production in the Northwest Atlantic. Lower recruitment rates are evident throughout eastern Canada and USA. The $\mathrm{PFA}_{N A}$ forecast for 2007 has a median value of 113100 (Table 4.9.10.7). For 2008 and 2009, the $\mathrm{PFA}_{\mathrm{NA}}$ forecasts remain among the lowest in the time series. For 2008, the median value is 118000 fish and is highly unlikely to meet the 2SW spawner reserve of 212189 salmon to North America. For 2009, the median forecast value is 114200 , also highly unlikely to meet the 2SW spawner reserve to North America (Table 4.9.10.7).

### 5.6.2 Southern European MSW stock complex

The southern European PFA forecast for 2007 has a median value of 455415 (Table 3.6.1.2). The spawning escapement to southern Europe MSW stocks has not exceeded CLs throughout most of the time period (Figure 3.1.1). The PFA for NEAC MSW southern stock complex is expected to decline in 2008 and 2009 (Figure 3.6.1.). For 2008, the median value is 434060 fish and for 2009, the median forecast value is 413701 fish. It is unlikely that spawner reserves will be met in either year.

### 5.7 Comparison with previous assessment and advice

The management advice for the West Greenland fishery has been the same since 2003. The current modelling approach has provided stable comparisons of the previous year predictions and updated $\mathrm{PFA}_{N \mathrm{~A}}$ in the last two years. For 2006, the median value of the updated analysis for NAC has decreased to 117431 fish from the 119000 predicted in the previous year's analysis. The variability of the two predictions was similar. The revised forecast of the southern NEAC MSW PFA for 2006 provides a PFA mid-point of 483700 . This is close to the value forecast last year at this time of 489000.

### 5.8 NASCO has requested ICES to describe the events of the 2006 fishery and status of the stocks

### 5.8.1 Catch and effort in 2006

By the end of the season a total of 20.7 t of landed salmon were reported (Table 5.8.1.1). In total, 236 reports were received, a $61 \%$ increase from the 145 last year. Catches were distributed among the six NAFO divisions on the western coast of Greenland (Figure 5.8.1.1), with catches in 1A, 1D, and 1F higher than the other three divisions (Table 5.8.1.2). In 2006, catch was reported from week 32 to week 44 , with $44 \%$ of the catch by weight reported in week 44 and no more than $10 \%$ in any of the remaining weeks. Since 2003, the proportion of the catch reported in week 44 or later has ranged from $2 \%$ to $20 \%$. In late October 2006, the Greenland Home Rule License Office broadcast TV requests that catch reports be submitted for the season. Thus, it is possible that the temporal distribution of reported catch in 2006 reflects changes in reporting practice.

In 2006 a total of 136 people landed salmon, with five reporting landings in more than one NAFO Division. The number of fishermen reporting catches has steadily increased from approximately 40 to 136 over the last 5 years, but is below the 400 to 600 people reporting landings in the commercial fishery 1987 to 1991. There is presently no quantitative approach
for estimating the unreported catch. However, in 2006 it is likely to have been at the same level proposed in recent years (10 t).

### 5.8.2 Biological characteristics of the catches

The international sampling program for landings at West Greenland initiated by NASCO in 2001 was continued in 2006. The sampling teams from Greenland, Ireland, UK (Scotland), UK (England \& Wales), Canada, and United States were in place at the start of the fishery and continued through October. Tissue and biological samples were collected from five landing sites: Qaqortoq (NAFO Div. 1F), Paamiut (NAFO Div.1E), Nuuk (NAFO Div. 1D), Maniitsoq (NAFO Div. 1C), and Ilulissat (NAFO Div. 1A) (Figure 5.8.1.1). In total 1253 salmon were inspected for the presence of tags, representing $25 \%$ by weight of the reported landings. Of these, 1104 were measured for fork length and weight, and scales were collected from 1118 (Table 5.8.2.1). Tissue was removed for DNA analysis from 1193 salmon. The broad geographic distribution of the subsistence fishery caused practical problems for the sampling teams. However, temporal coverage was adequate to assess the fishery. Unlike in previous years, the Working Group did not need to adjust the total landings by replacing the reported catch with the weight of fish sampled to use in assessment calculations (Table 5.8.2.2).

The average weight of a fish from the 2006 catch was 3.24 kg across all ages, with North American 1SW fish averaging 65.3 cm and 3.10 kg whole weight and European 1SW salmon averaging 65.3 cm and 3.25 kg (Table 5.8.2.3). The mean lengths and mean weights for the 2006 samples were among the highest in the last decade. It should be noted that the average weight is not adjusted for standard week and may not represent a true increase in mean weight over years.

North American salmon up to river age 6 were caught at West Greenland in 2006 (Table 5.8.2.4), with approximately $44 \%$ being river age 3 and $27 \%$ being river age 4 . The river ages of European salmon ranged from 1 to 5 (Table 5.8.2.4). Over half (54\%) of the European fish in the catch were river-age 2 and $23.6 \%$ were river age 3 . The proportion of the European origin river age 1 salmon in the catch has ranged been between $9 \%$ and $19 \%$ since 2001 (Table 5.8.2.4).

In 2006, 98.8 \% of the European samples were 1SW salmon, with previous spawners $1.2 \%$ of the samples (Table 5.8.2.5). 1SW salmon dominated (93\%) the North American component, with previous spawners decreasing to $5.6 \%$ from $6.4 \%$ of the samples last year (Table 5.8.2.5).

Tissue for disease testing was obtained from 119 whole fish in Nuuk. These samples were tested for the presence of ISAv by RT-PCR assay only and all test results were negative. The sex was determined by examining gonads for 121 salmon ( 119 whole and 3 viscera); of these 23 (18\%) were males and 98 (82\%) females.

### 5.8.3 Continent of origin of catches at West Greenland

Of the 1193 samples collected for genetic characterization, most (1042) were genotyped at four microsatellites (Ssa202, Ssa289, SSOSL438, and SSOSL311). Two samples were removed from the analysis and the remainder were genotyped at $2(n=3)$ or $3(n=146)$ loci. A database of approximately 5000 Atlantic salmon genotypes of known origin was used as a baseline to assign these salmon to continent of origin. In total, $72 \%$ of the salmon sampled from the 2006 fishery were of North American origin and $28 \%$ fish were of European origin.

The continent of origin of the samples varied among the divisions in 2006 (see table below) (Chi Square $\mathrm{p}=0.019$ ). The Working Group recommends a broad geographic sampling program (multiple NAFO divisions) to more accurately estimate continent of origin in the mixed stock fishery.

| NAFO <br> division | North America |  | Europe |  |
| :---: | ---: | ---: | ---: | :---: |
|  | Number | $\%$ | Number | $\%$ |
| 1A | 33 | $56 \%$ | 26 | $44 \%$ |
| 1C | 81 | $64 \%$ | 45 | $36 \%$ |
| 1D | 620 | $74 \%$ | 218 | $26 \%$ |
| 1E | 25 | $61 \%$ | 16 | $39 \%$ |
| 1F | 98 | $77 \%$ | 29 | $23 \%$ |
| Total | 857 | $72 \%$ | 334 | $28 \%$ |

Applying the continental percentages for the NAFO division catches resulted in estimates of 14.3 t of North American origin and 6.4 t of European origin fish (4000 and 1800 rounded to the nearest 100 fish, respectively) landed in West Greenland in 2006 (Table 5.8.3.1 and Figure 5.8.3.1).

### 5.8.4 Elaboration on status of the stocks in the West Greenland Commission area

MSW stocks from North America and southern Europe contribute to the fishery at West Greenland. The percentage of North American salmon in the West Greenland catch has averaged approximately $70 \%$ from 2000-2005 (Table 5.8.3.1).

### 5.8.4.1 North American Stock

Estimates of pre-fishery abundance suggest a continuing decline of North American adult salmon over the last 10 years. The total population of 1SW and 2SW Atlantic salmon in the northwest Atlantic has declined since the 1970s (Figure 4.9.10.1). During 1994-2006, the total population of 1 SW and 2 SW Atlantic salmon was about 600000 fish, about half of the average abundance during 1972-1990. The decline from earlier higher levels of abundance has been more severe for the 2 SW salmon component than for the small salmon (maturing 1SW salmon) age group.

In most regions, the returns of 2SW fish in 2006 increased slightly from 2005, however, they are still close to the lowest of the 35-year time-series (1972-2006). In 2006, the estimated overall spawning escapement was below the CL for the stock complex. Specifically 2SW spawners in the regions are:

- Newfoundland: at risk of suffering reduced reproductive capacity ( $112 \%$ of 2SW CL)
- Labrador: suffering reduced reproductive capacity ( $40 \%$ of 2SW CL)
- Québec: suffering reduced reproductive capacity ( $65 \%$ of 2SW CL)
- Gulf of St. Lawrence: suffering reduced reproductive capacity (86\% of 2 SW CL)
- Scotia-Fundy: suffering reduced reproductive capacity (10\% of 2SW CL)
- United States: suffering reduced reproductive capacity (6\% of 2SW CL)

### 5.8.4.2 Southern European Stock

Estimates of pre-fishery abundance suggest a downward trend in Southern European MSW adult salmon over the last 10 years. The midpoint of spawners has been close to or below CLs in recent years. Specifically:

- Southern European stock complex: suffering reduced reproductive capacity (82\% of 2SW CL)

### 5.9 NASCO has requested ICES to provide a detailed explanation and critical examination of any changes to the models used to provide catch options

### 5.9.1 Run-reconstruction models

The run-reconstruction models to estimate pre-fishery abundance of 1 SW non-maturing and maturing 2SW fish adjusted by natural mortality to the time prior to the West Greenland fishery are the same as those used since 2003 (ICES, 2003, 2004, 2005, 2006). See Sections 4.9.10 and 3.8.9 for additional details.

### 5.9.2 Forecast models for pre-fishery abundance of 2SW salmon

The forecast models used to estimate pre-fishery abundance of non-maturing 1SW salmon (potential MSW) from the Southern European stock group were the same as those used since 2002 (ICES, 2002, 2003, 2004, 2005, 2006). The overall approach is to select the best model by adding variables (eg. spawners, habitat, PFA of maturing 1SW salmon and year) until addition of any other parameter was not significant. See Section 3.6 for details.

The forecast models used to estimate pre-fishery abundance of non-maturing 1SW salmon (potential MSW) for North America were the same as those used since 2004 (ICES, 2004, 2005,2006 ). The overall approach of modelling the natural $\log$ transformed $\mathrm{PFA}_{\mathrm{NA}}$ and $\mathrm{LS}_{\mathrm{NA}}$ using linear regression and the Monte Carlo method used to derive the probability density for the $\mathrm{PFA}_{\mathrm{NA}}$ forecast was also retained from previous years. See Section 4.9.10 for details.

### 5.9.3 Development and risk assessment of catch options

The provision of catch options in a risk framework involves incorporating the uncertainty in the factors used to develop the catch options. The ranges in the uncertainties of all the factors will result in assessments of differing levels of precision. The analysis of risk involves four steps: 1) identifying the sources of uncertainty; 2) describing the precision or imprecision of the assessment; 3) defining a management strategy; and 4) evaluating the probability of an event (either desirable or undesirable) resulting from the fishery action. Atlantic salmon are managed with the objective of achieving spawning CLs. The undesirable event to be assessed is that the spawning escapement after fisheries will be below the CL.

The risk assessment for the two stock complexes in the West Greenland fishery is developed in parallel and then combined at the end of the process into a single summary plot or catch options table (Figure 5.9.3.1). The primary inputs to the risk analysis for the complex at West Greenland are:

- PFA forecast for the year of the fishery; $\mathrm{PFA}_{\text {NA }}$ and $\mathrm{PFA}_{\text {NEAC }}$
- Harvest level being considered (t of salmon)
- Conservation spawning limits

The uncertainty in the $\mathrm{PFA}_{N A}$ and $\mathrm{PFA}_{\text {NEAC }}$ is accounted for in the approaches described below. The number of fish of North American and European origin in a given catch ( $t$ ) is conditioned by the continent of origin of the fish $\left(\operatorname{prop}_{\mathrm{NA}}, \operatorname{prop}_{\mathrm{E}}\right)$, by the average weight of the fish in the fishery $\left(\mathrm{Wt}_{1} \mathrm{SW}_{\mathrm{NA}}, \mathrm{Wt}_{\mathrm{L}} \mathrm{SW}_{\mathrm{E}}\right)$ and a correction factor by weight for the other age groups in the fishery (ACF). For the 2007 to 2009 fisheries, it was assumed that the
 the ACF (1.0245-1.0985) could vary uniformly within the values observed in the past five years.

For a level of fishery under consideration, the weight of the catch is converted to fish of each continent's origin and subtracted from one of the simulated forecast values of $\mathrm{PFA}_{N A}$ and
$\mathrm{PFA}_{\text {NEAC }}$. The fish that escape the Greenland fishery are immediately discounted by the fixed sharing fraction (Fna) historically used in the negotiations of the West Greenland fishery. The sharing fraction chosen is the 40:60 West Greenland:North America split. The same sharing arrangement was assumed for NEAC stocks. Any sharing fraction can be considered and incorporated at this stage of the risk assessment. After the fishery, fish returning to home waters are discounted for natural mortality from the time they leave West Greenland to the time they return to rivers. For North America this is a total of 11 months at a rate of $\mathrm{M}=0.03$ (equates to $28.1 \%$ mortality). For Southern European stocks this is a total of 8 months at a rate of $M=0.03$ (equates to $21 \%$ mortality). The fish that survive to North American homewaters are then distributed among the regions and the total fish escaping to each region is compared to the region's 2 SW spawning requirements.

The final step in the risk analysis of the catch options involves combining the conservation requirement with the probability distribution of the returns to North America for different catch options. The returns to North America are partitioned into regional returns based on the regional proportions of 2SW returns of the last five years, 2002 to 2006. Estimated returns to each region are compared to the conservation objectives of Labrador, Newfoundland, Quebec, and Gulf. Estimated returns for Scotia-Fundy and USA are compared to the objective of achieving an increase of $10 \%$ and $25 \%$ relative to average returns of the base period, 19921996.

### 5.9.4 Critical Evaluation

Any changes to the run-reconstruction and pre-fishery abundance forecast models would have been critically examined in Sections 3.8 and 4.9. There were no changes to the risk assessment of catch options model.

### 5.10 NASCO has requested ICES to provide any new information on the extent to which the objectives of any significant management measures introduced in recent years have been achieved

NASCO management is directed at reducing exploitation to allow river specific CLs to be achieved. The first measurable outcome of management at West Greenland is that the exploitation in the fishery has declined (Figure 5.1.1). The other measures relate to increasing spawning escapement in homewaters. Although influenced by measures taken in homewaters, it is possible to directly evaluate the extent to which management at West Greenland successfully achieved the objectives (Table 5.10.1).

To date the objective of simultaneous attainment of CLs in Labrador, Newfoundland, Quebec and Gulf of St Lawrence has not been achieved. Nor has there been a $10 \%$ or $25 \%$ increase in spawners to either Scotia-Fundy or the USA. The objective of consistently meeting the CLs for the Southern NEAC MSW complex has not as yet been achieved.

Table 5.3.1. A - Lagged spawners achieved, 2SW conservation limits and the PFA number of fish required to meet region specific conservation limits if the returns to the regions are in proportion to the average lagged spawner distributions of 2002 to 2006. B - 2SW returns to the regions of North America for two time periods, 1992-1996, 2002-2006. C - Management objectives for the NAC area used to develop the risk analysis of catch options for the 2007 to 2009 fisheries.

${ }^{1}$ The fishery was suspended.
${ }^{2}$ Quota corresponds to specific opening dates of the fishery.
${ }^{3}$ Quota for 1988-90 was 2520 t with an opening date of 1 August and annual catches not to exceed the annual average ( 840 t ) by more than $10 \%$. Quota adjusted to 900 t in 1989 and 924 t in 1990 for later opening dates.
${ }^{4}$ Set by Greenland authorities.
${ }^{5}$ Quotas were bought out.
${ }^{6}$ Quota set to nil, fishery restricted to catches used for internal consumption in Greenland.
${ }^{7}$ Calculated final quota in ad hoc management system.
${ }^{8}$ No factory landing allowed.
${ }^{9}$ Maximum allowable catch
${ }^{10}$ For the assessments the Working Group used higher catch figures based on information from the sampling programme.

Table 5.8.1.2. Distribution of nominal catches (metric tons) by Greenland vessels (1977-2006).

Table 5.10.1. Assessing the objectives of NASCO management of the West Greenland fishery.

| Objective | Assessment | OUTCOME/EXTENT ACHIEVED | FURTHER Consideration |
| :---: | :---: | :---: | :---: |
| Reduce exploitation. | Assessment, reported and unreported landings compared to negotiated catch quotas for the fishery. | There in no Commercial Fishery (quota set at nil). The internal consumption fishery has no quota. | Reporting rate for the internal consumption fishery and reported catch increased in 2006. Estimates of unreported catch are unchanged. |
| $75 \%$ chance of meeting the conservation limits simultaneously in the four northern regions of North America | Assessment of returns to North America. Run reconstruction to estimate overall returns (Sec. 4.9) related to estimated spawning escapement reserve at West Greenland. | This objective has not yet been achieved. | Restrict fisheries on mixed stocks and stocks below Conservation Limits. Examine other limiting factors such as causes of increased marine mortality, habitat quality, predators etc. |
| $75 \%$ chance of achieving increases in returns relative to previous years with the hope that this leads to the rebuilding ScotiaFundy and USA stocks. | Assessment of returns to North America. Run reconstruction to estimate overall returns (Sec. 4.9). Improvements of greater than 10\% and greater than $25 \%$ relative to returns are evaluated (Sec 4.9) | This objective has not been achieved. | Restrict fisheries on mixed stocks and stocks below Conservation Limits. Examine other limiting factors such as causes of increased marine mortality, habitat quality, predators etc. Recovery plans developed for the stocks listed as endangered/ at risk. |
| 75\% chance of meeting spawner escapement requirement for the Southern NEAC MSW complex. | Assessment of returns to Southern NEAC. Run reconsruction to estimate overall returns (Sec. 3.3) related to estimated spawning escapement reserve at West Greenland. | This objective has not been achieved. | Restrict fisheries on mixed stocks and stocks below Conservation Limits. Examine other biologically limiting factors such as causes of increased or high marine mortality, habitat quality, bycatch, predators etc. |

Figure 5.1.1. Exploitation rate for non-maturing 1SW Atlantic salmon at West Greenland, estimated from harvest and PFA of North American non-maturing 1SW salmon.

Figure 5.6.3.1. PFA estimated for North American (NA) and European (E) non-maturing 1SW salmon contributing to the stock complex at West Greenland. Open symbols are forecast estimates.

Figure 5.8.1.1. Location of NAFO divisions along the coast of West Greenland.

Figure 5.8.3.1. Number of North American and European salmon caught at West Greenland, 1982-1992 and 1995-2006.

Figure 5.9.3.1. Flowchart, risk analysis for catch options at West Greenland using the PFA $_{\text {NA }}$ and the PFA NEAC $^{\text {predictions for the year of the fishery. Inputs with solid borders are considered }}$ known without error. Estimated inputs with observation error that is incorporated in the analysis have dashed borders. Solid arrows are functions that introduce or transfer without error whereas dashed arrows transfer errors through the components.

## 6 NASCO has requested ICES to identify relevant data deficiencies, monitoring needs and research requirements taking into account NASCO's international Atlantic salmon research board's inventory of on-going research relating to salmon mortality in the sea

The Working Group recommends that it should meet in 2008 to address questions posed by ACFM, including those posed by NASCO. The Working Group intends to convene in the headquarters of the Marine Institute in Galway, Ireland from $1^{\text {st }}$ to $10^{\text {th }}$ April 2008. It is strongly recommended by the Working Group that this period is adhered to in order to provide sufficient time to adequately review and complete the report.

### 6.1 Data deficiencies and research needs.

## Recommendations from Section 2 - Atlantic salmon in the North Atlantic Area:

3 ) The Working Group recommends that a second workshop be held to complete the collation of historical tag data initiated by the Workshop on the Development and Use of Historical Salmon Tagging Information from Oceanic Areas (WKDUHSTI) and further examine the available datasets in relation to pertinent environmental and oceanographic information. The standardized, collated dataset from this workshop will provide opportunities to conduct more detailed analysis of historical marine growth, mortality and oceanic distribution and migration patterns.
4) The Working Group recommends the facilitation of research using new and evolving technologies (e.g. acoustic tags, DST and popup tags) and techniques (e.g. use of kelts) and recommends further presentations from countries on the approaches taken to address questions on the marine ecology of Atlantic salmon. The co-ordination of efforts between countries would improve studies into the migration routes and early marine ecology of Atlantic salmon to further the presently limited understanding of the factors influencing marine survival.

5 ) The Working Group recommends the review and standardization of circuli spacing techniques with particular consideration of recently available analytical technologies such as computer assisted image analysis. These techniques provide opportunities to sharing and co-ordinate the examination of scale material available from different research agencies (or from different stocks and stock components) to identify spatial and temporal anomalies in the time series of scale growth during the marine phase, which may indicate common causes or factors influencing mortality.

6 ) The Working Group recognises the movement to river specific management which requires more extensive monitoring on individual river basins and recommends continued and extended monitoring programmes.

7 ) The Working Group recommends that coordinated efforts are made to collate information on biological characteristics (e.g. juvenile size at age (freshwater growth), smolt age composition, smolt run timing (and autumn parr movements), post-smolt growth, sea-age composition, size at return (marine growth), adult run timing and sex ratios) throughout the geographic range.

## Recommendations from Section 3 - Fisheries and Stocks from the North East Atlantic Commission Area:

4) The Working Group recognizes the current limitations associated with forecasting pre-fishery abundances in the NEAC area pose difficulties in providing management advice for the Faroese fishery. The Working Group recommends that a study group be held to further develop and refine pre-fishery abundance forecast models.

## Recommendations from Section 4 - Fisheries and Stocks from the North American Commission Area:

No recommendations from section 4.

## Recommendations from Section 5 - Atlantic Salmon in the West Greenland Commission Area:

1) The Working Group recommends that the Home Rule Government of Greenland continue to provide information on the extent of fishing activity by all license holders. These inputs are essential to provide management advice on mixed stock fisheries at Greenland.
2) The Working Group recommends a broad geographic sampling program (multiple NAFO divisions) to more accurately estimate continent of origin in the mixed stock fishery. These inputs are essential to provide management advice on mixed stock fisheries at Greenland.

## Annex 4 continued

1. MSW includes all sea ages $>1$, when this cannot be broken down

Different methods are used to separate $1 . \mathrm{W}$ and M. W salmon in diferent counfrie
Scale reading. Faroe Islands, Finland (1996 onwards), France, Russia, USA and West Greenland
Size (split weightflength): Canada ( 2.7 kg for nets; 63 cm for rods), Finland up until 1995 ( 3 kg ),
Iceland (various splits used at different times and places), Norway ( 3 kg ), UK Scotland ( 3 kg in some places and 3.7 kg in others),
All countries except Scotland report no problems with using weight to catergorise catches into sea age classes, mis-classification may be very high in some years.
In Norway, catches shown as 3 SW refer to salmon of 3 SW or greater
Based on catches in Asturias ( $80-90 \%$ of total catch)

# Annex 5(i): Estimated numbers of 1SW salmon returns, recruits and spawners for Labrador

Estimates are based on:
EST LARGE RETURNS - (COMM CATCH*PROP LAB ORIGIN)/EXP RATE, PROP SFAs1,2\&14B=.6-.8,SFA 1: 0.64-0.72 \& SFA $20.88-0.95$ (97);
EXP RATE-SFAs1,2\&14B=.7-.9(69-91),.58-.83(92),.38-.62(93),.29-.50(94), . 15-.26(95), . 13-.23(96), - SFA 1: 0.22-0.40, SFA 2: 0.16-0.28 (97)
EST 2SW RETURNS - (EST LARGE RETURNS*PROP 2SW), PROP 2SW SFA $1=.7-.9$, SFAs $2 \& 14 \mathrm{~B}=.6-.8$
WG - are North American 1SW salmon of river age 4 and older of which 70\% are Labrador origin
EST RET TO FRESHWATER - (EST 2SW RET-2SW CATCHES)
EST 2SW SPAWNERS = EST 2SW RETURNS TO FRESHWATER - 2SW ANGLING CATCHES
*Catches for 1969-73 are Labrador totals distributed into SFAs as the proportion of landings by SFA in 1974-78.
**1997 Preliminary values adjusted for size category and SFA 14B recruits derived as 0.0426 of SFAs $1+2$ based on proportionate drainage areas
Returns in 1998-2001 were estimated from regression
Returns in 2002 to present are from counting fence returns and drainage areas

Annex 5(iii). Atlantic salmon returns to freshwater, total recruits prior to the commercial fishery and spawners summed for Salmon Fishing Area 3-14A, insular Newfoundland, 1969-2006.

Annex 5 (iii). Atlantic salmon returns to freshwater, total recruits prior to the commercial fishery and spawners summed for Salmon Fishing Area 3-14A, insular Newfoundland, $1969-2006$
Ret. = retained fish; Rel. = released fish.

SRR (Small returns to river ) are the sum of Bay St. George small returns (Reddin \& Mullins 1996)
plus Humber R small returns (Mullins \& Reddin 1996) plus small returns in SFAs $3-12 \& 14 \mathrm{~A}$.
$\operatorname{SSR}$ (Small recruits) $=\operatorname{SRR} /(1-$ Exploitation rate commercial (ERC)) where $E R C=0.5-0.7,1969-91 \& E R C=0,1992-98$.
SS (Small spawners) $=$ SSR-(SC $+\left(\mathrm{SR}^{*} 0.1\right)$ )
SR = small salmon catch released with assumed mortalities at $10 \%$
RL (RATIO large:small) are from counting facilities in SFAs $3-11,13 \& 14 \mathrm{~A}$, angling catches in SFA 12
$\operatorname{LR}$ (Large recruits) $=\operatorname{LRR} *(1-$ Exploitation rate large (ERL)), where ERL=0.7-0.9, 1969-91; \& ERL=0, 1992-98,
LS (Large spawners) $=\operatorname{LRR}$-large catch retained ( LC)-( $\left(0.11^{*}\right.$ arge catch released)
$2 S W$-RR ( $2 S W$ returns to river $)=$ LRR
2SW-RR (2SW returns to river) = LRR*proportion 2SW of 0.4-0.6 for SFA $12-14 \mathrm{~A}$ \& 0.1-0.2 for SFAs 3-11.
$2 S W-R$ (2SW recruits) $=$ LR * proportion 2 SW of 0.4-0.6 for SFAs 12-14A\& $0.1-0.2$ for SFAs $3-11$.

Annex 5(iv): Small, large, and 2SW return and spawner estimates for SFA 15.

SFAs 19, 20, 21: Returns, 1970-1997, estimated as run size (1SW recreational catch / expl. rate [0.2 to 0.45$]$; where MIN and MAX selected as 5 th and 95 th percentile values from 1,000 monte carlo estimates) + estimated 1 SW fish in commercial landings 1970-1983 (Cutting MS 1984). For 1998 2004, see "a" below.
SFA 22: Inner Fundy stocks and inner-Fundy SFA 23 (primarily 1 SW fish) do not go to the North Atlantic.
 (commercial harvest, bi-catch etc., incl. in estimated returns); hatchery returns attributed to above Mactaquac only; 1 SW production in rest of SFA (outer Fundy) omitted.
Revision of method, SFA 23, 1993-2004, estimated returns to Nashwaak fence raised by proportion of area below Mactaquac (0.21-0.30)
"and added to total estimated returns originating upriver of Mactaquac (Marshall et al. 1998); MIN and MAX removals below Mactaquac pased Nashwaak losses, Mactaquac losses are a single value ond together summed and removed from returns to establish estimate of spawners SFA 19-21, estimate of returns 1998-2004 based on regression (revised in March 2005 with intercept set to zero) of LaHave wild counts on MIN and MAX estimates of total SFA 19-21 returns, 1984-1997, because there was no ( $1998,2000-04$ ) \& little (1999) angling in SFAs $20-21$.

## Annex 5(ixa): Total 2SW returns to SFAs 19, 20, 21 and 23, 1970 to 2006

Appendix 5 (ixa). Total 2SW returns to SFAs 19, 20, 21 and 23, 1970-2006.

SFAs 19, 20, 21: Returns, 1970-97 estimated as run size (MSW recreational catch * prop. 2 SW [range of values]/ expl. rate [range of values]; where MIN and MAX selected as 5 th and 95 th percentile values from 1,000 monte carlo estimates) + estimated 2 SW Commercial landings 1970-1983 (Cutting MS 1984). For 1998-2004 see "a" below.
SFA 22: Inner Fundy stocks do not go to north Atlantic.
SFA 23: For 1970-1997 Similar approach as for SFAs $19-21$ except that estimated wild MSW returns destined for Mactaquac
Dam, Saint John River, replaced values for recreational catch; and estimated proportions that production above Mactaquac is of the Dam, Saint John River, replaced values for recreational catch; and estimated proportions that production above Mactaquac is of the returns to Mactaquac; 2SW production in rest of SFA omitted. Note revisions to returns from 1993 to 2005 made in 2005 .
Revision of method, SFA 23, 1993-2005, estimated MSW returns to Nashwaak fence raised by prop. of area below
"actaquac ( $0.21-0.30$ ) * prop. 2 SW ( 0.7 \& 0.9 ) and added to estimated MSW hatchery and wild returns * (Marshall et al. MS 1998 ( $0.85-0.95 ; 2$ 2SW) originating upriver of Mactaquac. MIN \& MAX removals below Mactaquac based on Nashwaak losses: Mactaqua losses were a single value and together summed and removed from MSW returns (prevousty) to estimate spawners. SFAs 19-21, estimate of 2 SW returns for 1998-04, based on regression (revised in March 2005 with intercept set to zero) of LaHave.

Annex 5(ixb): Total 2SW spawners in SFAs 19, 20, 21 and 23, 1970-2006
Appendix 5(ixb). Total 2SW spawners in SFAs 19, 20, 21 and 23, 1970-2006.

Spawners = returns minus removals where: "returns" are from previous Appendix as are outlines of revisions to methods for SFAs 19-21, 1998-2000, and SFA 23, 1993-2000. "Removals" of 2SW fish in SFAs 19-21 have been few, largely illegal and unascribed since the catch-and-release angling regulations in 1985; removals in SFA 23, 1985-1997, had been in total, the assessed losses to stocks originating above Mactaquac. The revised Mactaquac as well as the previously assessed and used values for stocks upstream of Mactaquac.

Annex 5(x): Estimated numbers of salmon returns and spawners for Québec 1969-2006

| Year | Recruit of small salmon |  | Recruit of large salmon |  | Spawner of small salmon |  | Spawner of large salmon |  |

## Annex 7: Glossary of acronyms used by the Working Group on North Atlantic Salmon, 2007

1SW (One-Sea-Winter) Maiden adult salmon that has spent one winter at sea.
2SW (Two-Sea-Winter) Maiden adult salmon that has spent two winters at sea.
ASAP (The Atlantic Salmon Arc Project) The initial aim of ASAP is to collect samples from the majority of salmon rivers on the Western Atlantic coast of Europe and use methods of Genetic Stock Identification (GSI).

BHSRA (Bayesian Hierarchical Stock and Recruitment Approach) Models for the analysis of a group of related stock-recruit data sets. Hierarchical modeling is a statistical technique that allows the modeling of the dependence among parameters that are related or connected through the use of a hierarchical model structure. Hierarchical models can be used to combine data from several independent sources.

CL, i.e. $\mathbf{S}_{\text {lim }}$ (Conservation Limit) Demarcation of undesirable stock levels or levels of fishing activity; the ultimate objective when managing stocks and regulating fisheries will be to ensure that there is a high probability that undesirable levels are avoided.

CPUE (Catch Per Unit Effort) A derived quantity obtained from the independent values of catch and effort.

CWT (Coded Wire Tag) The CWT is a length of magnetized stainless steel wire 0.25 mm in diameter. The tag is marked with rows of numbers denoting specific batch or individual codes. Tags are cut from rolls of wire by an injector that hypodermically implants them into suitable tissue. The standard length of a tag is 1.1 mm .

DST (Data Storage Tag) A miniature data logger with sensors including salinity, temperature, and depth that is attached to fish and other marine animals.

FV (Fishing Vessel) A vessel that undertakes cruise for commercial fishing purposes.
GIS (Geographic Information Systems) A computer technology that uses a geographic information system as an analytic framework for managing and integrating data.

GSI (Genetic Stock Identification) Methods used to 'genetically type' salmon from particular regions and rivers across Atlantic.

ISAV (Infectious Salmon Anemia Virus) ISA is a highly infectious disease of Atlantic salmon caused by an enveloped virus.

MSY (Maximum Sustainable Yield) The largest average annual catch that may be taken from a stock continuously without affecting the catch of future years; a constant long-term MSY is not a reality in most fisheries, where stock sizes vary with the strength of year classes moving through the fishery.

MSW (Multi-Sea-Winter) An adult salmon which has spent two or more winters at sea or a repeat spawner.

PFA (Pre-Fishery Abundance) The numbers of salmon estimated to be alive in the ocean from a particular stock at a specified time.

PGA (The Probabilistic-based Genetic Assignment model) An approach to partition the harvest of mixed stock fisheries into their finer origin parts. PGA uses Monte Carlo sampling to partition the reported and unreported catch estimates to continent, country and within country levels.

PIT (Passive Integrated Transponder) PIT tags use radio frequency identification technology. PIT tags lack an internal power source. They are energized on encountering an
electromagnetic field emitted from a transceiver. The tag's unique identity code is programmed into the microchip's nonvolatile memory.

Q Areas for which the Ministère des Ressources naturelles et de la Faune manages the salmon fisheries in Québec.

RT-PCR (Reverse Transcription-Polymerase Chain Reaction) is the most sensitive technique for mRNA detection and quantitation currently available. Compared to the two other commonly used techniques for quantifying mRNA levels, Northern blot analysis and RNase protection assay, RT-PCR can be used to quantify mRNA levels from much smaller samples.

RV (Research Vessel) A vessel that undertakes cruises to conduct scientific research.
SAC (Special Areas of Conservation) To comply with the EU Habitats Directive (92/43/EEC) on Conservation of Natural Habitat and of Wild Fauna and Flora, which stipulates that member states maintain or restore habitats and species to favourable conservation status, a number of rivers in the NEAC area that support important populations of vulnerable qualifying species have been designated SACs. Where salmon is a "qualifying species", additional protection measures specifically for salmon are required.

SER (Spawning Escapement Reserve) The CL increased to take account of natural mortality between the recruitment date ( $1^{\text {st }}$ January) and return to home waters.

SFA (Salmon Fishing Areas) Areas for which the Department of Fisheries and Oceans (DFO) Canada manages the salmon fisheries.

SGBYSAL (Study Group on the Bycatch of Salmon in Pelagic Trawl Fisheries). The ICES Study Group that was established in 2005 to study Atlantic salmon distribution at sea and fisheries for other species with a potential to intercept salmon.

SGEFISSA (Study Group on Establishing a Framework of Indicators of Salmon Stock Abundance) A Study Group established by ICES and met in November 2006.
$\mathbf{S}_{\text {lim, }}$, i.e. CL (Conservation Limit) Demarcation of undesirable stock levels or levels of fishing activity; the ultimate objective when managing stocks and regulating fisheries will be to ensure that there is a high probability that the undesirable levels are avoided.

TAC (Total Allowable Catch) The quantity of fish that can be taken from each stock each year.

VHSV (Viral Haemorrhagic Septicaemia Virus) VHS is a highly infectious virus disease caused by the virus family Rhabdoviridae, genus Novirhabdovirus.

VIE (Visual Implant Elastomer) The VIE tags consist of fluorescent elastomer material which is subcutaneously injected as a liquid into transparent or translucent tissue via a hand-held injector.

WFD (Water Framework Directive) Directive 2000/60/EC (WFD) aims to protect and enhance the water environment, updates all existing relevant European legislation, and promotes a new approach to water management through river-based planning. The Directive requires the development of River Basin Management Plans (RBMP) and Programmes of Measures (PoM) with the aim of achieving Good Ecological Status or, for artificial or more modified waters, Good Ecological Potential.

WKDUHSTI (Workshop on the Development and Use of Historical Salmon Tagging Information from Oceanic Areas) The Workshop established by ICES was held in February 2007.

This glossary has been extracted from various sources, but chiefly the EU SALMODEL report (Crozier et al.., 2003).

## Annex 8: Technical minutes from the ACFM Review Group on Salmon

ICES 30 April - 3 May 2007.

## Participants:

Tim Sheehan, Martin Pastoors, Denis Rivard, Atso Romakkaniemi, Vidar Vennevik, Paivi Haapasaari, Henrik Sparholt, Catherine Michielsen.

## General

Section 3.7.1 "...Changes were also made to non-reporting rates to better reflect current knowledge..." There should be more details explaining this. Iceland should have presented a working paper documenting these changes so that the WG could evaluate these changes and could explain them to ACFM.

In the Table 3.9.1 the year that the specific measures are introduced and the years that they will be evaluated should also be included as separate columns.

It would be beneficial to try and develop a Bayesian based approach to model pre-fishery abundance to utilize all the available information similar to the Baltic approach. As an example the smolt abundance and marine survival estimates are not used in the present models. This is regarded as a weakness in the modelling. If these efforts are undertaken, it would be informative to run the current model and the Bayesian based model concurrently for a number of years.

Close communication with the Baltic Salmon WG might be useful. Maybe the wgs could meet back to back.

## Fisheries data

In the NAC area, the un-reported catch was estimated at 56 t with 136 t of reported catch. The unreported catch is a significant amount and is underestimated and expected to be updated in 2008. ICES expressed concerned over such a high rate of unreported catch relative to the reported catch. In addition, the 2006 NAC unreported catch was reported as 101 t in the 2006 report, but has been changed to 85 t in the 2007 report. ICES noted this difference and the lack of explanation for the change in reported catch. It would be nice to have a better description of the nature of the misreporting and how they have been estimated. A full description of estimating unreported catches for all stock complexes could be detailed in the Quality handbook.

## Management

In 2006 for the first time NASCO agreed 3 yr regulatory measures with $2^{\text {nd }}$ and $3^{\text {rd }}$ year dependent on the acceptance of a finalised FWI.

ICES notes that there no explicit management objectives for managing the NEAC stock complexes (i.e. Faroese fishery).

The FWI could be incorporated into a HCR (Harvest Control Rule) and evaluated as an integrated analysis. In this way the approach for salmon would be more in line with what is done for other fish species stocks.

There were some questions raised about whether the PA was served when aggregating information for indicators and indicator-rivers. However, it was noted that the FWI aggregates indicators within the West Greenland FWI according to the explicit management objectives for that fishery.

The wg has developed a spread sheet with the indicators that can be used by NASCO if they continue on the route of the multi-annual management agreement, with an indicator framework.

Sea survival is the main issue with both the Atlantic and the Baltic salmon stocks.
There will be a need for resolving precisely how the FWI will be arranged between NASCO and ICES.

## NEAC

Same models used as in past many years.
The model was considered to some extent. It was found that the relationship between lagged spawners and PFA in fact is a kind of S-R model as lagged spawner is a kind of index of S and PFA is a kind of an index of recruitment. It might thus seem strange that the model fit is giving a concave curvilinear relationship as opposed for instance to a B\&H one which is convex.

The conservation limit definitions were discussed. The hockey stick model is used on a national basis and when river specific data are available this is the basis for the conservation limit. The WG seems to make good progress on developing river specific conservation levels.

Forecast models do not exist for three of the four NEAC stock complexes. This hinders the WG ability to provide quantitative management advice for the Faroese fishery.

In order to give forecast for Faroe for 3 years ahead it is needed to give advice to and including 2010. To do this the 5 year mean of the contribution of 1 year smolts to the lagged egg variable was assumed. The contribution of 1 year smolts to the total lagged eggs is a very small proportion. The reason for the forecast needing to extend to 2010 is that the 2007 fishing (from October 2006 to march 2007) has already been decided upon.

The smolt age distribution is evaluated every 5 year in NA area and on a more national and ad hoc basis on the European side.

SGBYSAL was dissolved until data are more readily available.

## NAC stock complex

Current marine survival estimates should be compared to a standard measure (i.e. five year mean) rather than the previous year's estimate.

Same models used as in past many years.

## Greenland

Same models used as in past many years

## Research needs

NASCO seems to be evolving from negotiating quotas to more conservation/restoration mode and thus more towards facilitating science and communication among stakeholders, researcher and managers.

Further consideration should be given to the issue of marine survival. The SALSEA project and the numerous tagging and tracking efforts reported on are attempting to do this.

It was suggested that the European samples collected from West Greenland be further analysed to inform about which rivers in Europe is contributing to the West Greenland harvest and in what proportions. These further analyses are possible due to recent efforts which have bolstered the southern European Atlantic salmon genetic baseline.

The assessments were accepted as basis for the advice.

[^0]:    ${ }^{1}$ The number of microtagged hatchery fish in Iceland includes 18,326 fish reared in sea-pens.
    ${ }^{2}$ Pit tagged juvenile in Scotland also adipose finclipped.
    3 Includes all larger internal tags

[^1]:    ${ }^{1}$ Large numbers of new, inexperienced anglers in 1997 because cheaper licence types were introduced.

[^2]:    ${ }^{1}$ The fishery was suspended

    + Small catches $<0.5$ t
    - No catch
