NORWEGIAN INVESTIGATIONS ON THE DEEP SEA SHRIMP
(PANDALUS BOREALIS) IN THE BARENTS SEA IN APRIL -
MAY 1983 AND IN THE SPITSBERGEN AREA IN JULY 1983

by

Gunnar Teigsmark and Per Øynes
Institute of Marine Research
Bergen - Norway

ABSTRACT

This report describes the results from a stratified bottom trawl survey with R/V "Michael Sars" in April - May 1983 in the Barents Sea between $71^{\circ}30'N$ and $76^{\circ}00'N$, and between $16^{\circ}30'E$ and $35^{\circ}30'E$. The report also describes the results from a survey with the same ship in the Spitsbergen area between $74^{\circ}00'N$ and $80^{\circ}30'N$, and between $08^{\circ}00'E$ and $18^{\circ}00'E$ in July 1983. On the basis of the data from 107 trawl stations, the biomass of the shrimp, Pandalus borealis in the area surveyed in the Barents Sea was estimated to be approximately 368 000 tonnes. In the Spitsbergen area the biomass of the shrimp was estimated to be approximately 57 000 tonnes. The by-catches of fish in the hauls are also discussed.

INTRODUCTION

A stratified random sampling scheme was carried out during a bottom trawl survey with R/V "Michael Sars" from 25 April to 18 May 1983 in the Barents Sea (sub-area I). A similar sampling scheme was carried out during a bottom trawl survey with the same ship from 16 July to 29 July 1983 in the Spitsbergen waters (Division 2b).

The purpose of the cruises were to investigate the structure of the shrimp stock, the by-catches of fish and to estimate the abundance of shrimps.

MATERIAL AND METHODS

The cruises in 1983 covered the most important fields where commercial fishing for shrimp has been carried out in recent years in the Barents Sea. The boundaries of the strata are indicated in Fig. 1.

Due to great numbers of 1-group haddock in many shrimp fields, great areas were closed for the shrimp trawlers in the spring 1983. The main commercial fishing grounds in spring until June was only a small part of the "Nordkappleira" (strata 1-4) and the "Thor Iversen" field north of $73^{\circ}30'N$. A good fishing took also place near the Tiddly bank east of $33^{\circ}E$. The rest of the fishing grounds in strata 1-12 were closed for shrimp trawlers. Ice were not seen at all on the cruise with "Michael Sars" in the Barents Sea in 1983. As in the years before each stratum was sub-divided into rectangles of 5x5 nautical miles. Within each stratum, rectangles were given consecutive numbers starting from 1. Within each stratum the trawl stations were randomly allocated to rectangles. In the most important shrimp trawl fields 9% of the rectangles were trawled (strata 3, 4, 6, 7, 12 and 15), and in the other strata 5 - 6% were trawled. For further information on the methods see Teigsmark and Øynes 1981. The distance trawled was 3.0 nautical miles, but on some stations (station nos 4, 9, 63, 64 and 75) trawling had to be

much shorter due to rough or soft bottom. The numbers of hauls in each stratum are the same in 1983 as the year before except for the stratum 2 where only 2 stations instead of 4 could be taken due to soft bottom in these area. By-catches of fish were counted and length measurements were taken of all important species. In Table 1 the catch of shrimp (in kg) and by-catch of fish in the Barents Sea (in numbers) are listed. Fishing gear and techniques were the same as in the years before and are described by Tavares & Øynes (1980). The trawl stations in the Spitsbergen area are listed in Table 7.

The statistical treatment of the data follows Teigsmark & Øynes (1981). The width covered by the trawl is calculated to give an average width of 11.7 m.

The commercial stock, i.e. that part of the stock available to the commercially used 35 mm trawl-net, was calculated as in Teigsmark & Øynes (1981).

RESULTS AND DISCUSSION

Shrimps

Stock size estimate in the Barents Sea

Table 2 gives the estimated biomass of the total stock in each stratum in 1983. The total stock in all strata summarized is estimated to be 368 000 - 38 000 tonnes (Table 2). This corresponds to an increase of approximately 30% from 1982 for the strata investigated both years.

Table 3 gives the per cent change in biomass in the different strata from 1982 to 1983. In 1982 a decline was observed in stock size in the strata close to the Norwegian coast (Teigsmark & Øynes 1982). The same is observed in 1983. In most other strata a very marked increase in stock size has been observed, even in the very heavily fished areas (strata 6 - 7 and 10 - 12).

In the first half of the 1970'ies the Hopen area (strata 15 - 18) was the most important fishing area for shrimps in the Barents Sea. During this period the area was nearly fished out. In the last few years the shrimp stock in this area has been steadily increasing, and it has now attained a level that can sustain a profitable fishery.

The total stock is estimated to be $(70.1 \pm 7.2) \cdot 10^9$ individuals (Table 4). This corresponds to an increase of 5.3% from 1982. The commercial stock is estimated to be 328 000 \pm 35 000 tonnes (Table 5), corresponding to an increase of 39.2% from 1982. The commercial number of shrimps in 1983 is estimated to be $(56.3 \pm 5.9) \cdot 10^9$ individuals, i.e. an increase of 14.2% from 1982 (Table 6).

The size of the shrimp stock in the Barents Sea has been increasing during the last year and has now reached a very high level. This increase is obviously caused by the decline in the stock of Arcto-Norwegian cod during the same period. When the cod stock recovers, a very marked decline in the shrimp stock in the Barents Sea must be expected.

Stock size in the Spitsbergen area

The cruise in July 1983 covered the area from the "Kveithola" and northwards along the western slope at West-Spitsbergen up to north of Spitsbergen to $80^{\circ}30'N$. The stratified area (Fig. 2) was at depths from 200 m to 600 m. At the depth from 200 m to 400 m are used the same strata as were used in 1982 (strata 1 - 15). For the depths from 400 m to 600 m are used the numbers of strata from 16 to 22. The sampling localities are indicated in Fig. 2. Table 8 gives the estimated biomass of the shrimp stock in each stratum. For the entire area investigated this gives a total of 57 370 tonnes. For the strata investigated both years, this gives an increase of 3.9%.

The results from this cruise do confirm the main conclusions that could be drawn from the cruise in 1982 (TEIGSMARK & ØYNES

1983). Very low concentrations of small males (carapace length <16 mm) were found this year too, indicating poor prospects for a profitable shrimp fishing in this area in the years to come. Great changes in stock size have taken place from 1982 in many of the strata (Table 8). A high variability in stock size estimates between the different strata is observed this year too. This high variability, both within one stratum from one year to another, and between the strata in one single year, is one of the main difficulties in making an accurate evaluation of the state of the shrimp stock in this area.

By-catches

The Barents Sea

In Table 1 are listed by numbers the most economically important fish species for each trawl haul in the Barents Sea. Table 9 gives the by-catches (in numbers) in each stratum investigated. Here the numbers of fish are listed as mean number pr hour trawled (3 nautical miles).

In the winter 1983 there was a very high number of 1-group haddock at the shrimp fields in the Barents Sea. On some fields they could number as much as 2 to 4 thousand individuals per hour trawled. For that reason great areas were closed for the shrimp trawlers. At the time when the "Michael Sars" cruise started, the haddock at the shrimp fields had decreased much, only in the shallowest part of "Thor Iversen" bank there was still a great number of 1-group haddock (stratum 11). These 1-group haddock were present in all the strata investigated except in the area near Bjørnøya (strata 20 and 21). Cod was present in all the strata investigated. Altogether the catches of cod in the Barents Sea in 1983 were about 30% more in numbers than in 1982. Most of the cod were 1-group or other young fish. Redfish and Greenland halibut were found in approximately the same numbers as in 1982, mostly too small to be accepted for consumption in Norway. Capelin and Polar cod were less numerous in 1983 than in 1982 and was only sporadically found as by-catch in the shrimp fields in the Barents Sea.

The Spitsbergen area

In Table 7 are listed by numbers the by-catches of the most important fish species for each trawl haul. Table 10 gives the by-catches by mean number pr. hour trawled in each stratum investigated. The numbers of cod were about the same in 1983 as in the year before (TEIGSMARK & ØYNES 1983). The highest numbers of cod were found in the area near Bjørnøya. Only one single specimen of haddock was found in the investigated area and also in the area near Bjørnøya. Redfish was abundant in the deepest strata investigated with numbers from 1000 to 3300 pr. hour trawling. The Greenland halibut was present in the deepest strata investigated, but there were fewer individuals in 1983 than in 1982. The capelin was numerous only in strata 4 and 6, i.e. the most shallow part of the fields south of Spitsbergen. The by-catch of polar cod was low in 1983 compared with the numbers in the investigations in 1982.
