Exploration of the Sea

C.M. 1984/Assess:6

x)

**REPORT OF THE WORKING GROUP ON REDFISH AND GREENLAND
HALIBUT IN REGION 1**

Copenhagen, 22 - 27 February 1984

This document is a report of a Working Group of the International Council for the Exploration of the Sea and does not necessarily represent the views of the Council. Therefore, it should not be quoted without consultation with the General Secretary.

x) General Secretary
ICES,
Palægade 2-4,

REPORT OF THE WORKING GROUP ON REDFISH AND GREENLAND HALIBUT
IN REGION I

1. PARTICIPANTS AND TERMS OF REFERENCE

1.1 Participants

L Haumann	Denmark
K Kosswig	Federal Republic of Germany
E Lukmanov	USSR
J Magnusson	Iceland
J Møller Jensen	Denmark
N Prusova	USSR
K Randa	Norway
C Rørvik (Chairman)	Norway
H Schulz	Federal Republic of Germany
A Schumacher	Federal Republic of Germany
A Sigurdsson	Iceland

Mr K Hoydal attended the meeting as the ICES Statistician.

1.2 Terms of Reference

At the last Statutory Meeting the Council adopted the following resolution (C.Res. 1983/2:8:15):

The Working Group on Redfish and Greenland Halibut (Chairman, Mr C Rørvik) should meet at the ICES headquarters from 22-27 February 1984 to:

- (i) consider the findings of the Redfish Age-Reading Workshop,
- (ii) assess catch options for redfish and Greenland halibut in Region I for 1985 and, where meaningful, for 1986,
- (iii) evaluate available data, including information on cod, in relation to the "Mentella box" and the present mesh size regulation,
- (iv) analyse the effect of the changes in the data sets of weight at age and age at first maturity on the time series of the stock and spawning stock biomass.

2. REDFISH IN THE NORTH-EAST ARCTIC REGION (Sub-areas I and II)

2.1 Status of the Fisheries (Tables 1 - 5)

The redfish catches in the Sub-areas I and II increased from 102 372 tonnes in 1981 to 131 527 tonnes in 1982. The preliminary catch figure for 1983 is 117 149 tonnes, which is 32 149 tonnes above the level recommended by ACFM for 1983 of 85 000 tonnes. The 1983 catch is close to the agreed TAC for 1983 of 117 000 tonnes.

In Sub-area I the total catch increased from 2 565 tonnes in 1982 to 4 821 tonnes in 1983 (Table 2). In Division IIa the total catch increased from 79 151 tonnes in 1982 to 98 857 tonnes in 1983 (Table 3), and in Division IIb the catch decreased from 49 811 tonnes in 1982 to 13 471 tonnes in 1983 (Table 4).

Redfish catches were split into Sebastes mentella and Sebastes marinus on the same area basis as in earlier assessments. In Sub-area I all the USSR catches were reported to be S.mentella while the Norwegian catches were assumed to be S.marinus. In Division IIa the whole catch of the German Democratic Republic and 95% of the USSR catches were recorded as S.mentella, while all catches taken by other countries were assumed to be S.marinus. All catches taken in Division IIb were recorded as S.mentella.

Compared to 1982, the total landings in 1983 of S.marinus increased from 16 341 tonnes in 1982 to 18 128 tonnes in 1983, and those of S.mentella decreased from 115 100 tonnes to 99 021 in 1983 (Table 5). Thus, the TAC recommended by ACFM of 15 000 tonnes on S.marinus was exceeded by about 20%, while the recommended catch level for S.mentella of 70 000 tonnes was exceeded by about 40%.

2.2 Catch per Unit Effort (Table 6)

Catch per hour trawling data were available for the USSR S.mentella fishery for the period 1965-1983 from side trawlers (RT) and for 1980 to 1983 from stern trawlers (PST) (Table 6). The cpue value for side trawlers of 0.80 in 1983 is considerably above the value of 0.63 in 1982 which partly could be an effect of the change of minimum legal mesh size from 125 mm to 100 mm in the "Mentella box" (see also Section 6 below). The value for the stern trawlers (PST) shows an increase from 1.05 in 1982 to 1.09 in 1983. Using the side trawler (RT) cpue values as a standard, the total effort for the period 1965-1983 was derived. On this basis (RT) the total effort in 1983 was about 32% lower than in 1982.

The catch per unit effort for the German Democratic Republic S.mentella fishery, both for bottom trawl (OTB) and mid-water trawl (OTM) could not be given in 1983 due to a change in the

fishery. Instead a new catch per unit effort data for the category "freezer trawlers" in Division IIa were given for 1981-1983 (Table 6). This time series is too short to be used in the assessment.

2.3 Recruitment (Table 7)

From the International 0-group Survey, which began in the Barents Sea in 1965, it is seen that only year classes 1967 and 1968 have been estimated as very poor. The other year classes are all average or above average. The 1979-1983 year classes are the most abundant ones observed in the 0-group survey.

It should be noted that there is disagreement between the results from the International 0-group Surveys and the annual USSR Young Fish Surveys for the year classes 1973-1976. In the USSR Young Fish Surveys these year classes are recorded as poor. This is supported by the age-length composition of the USSR commercial catches in 1980-1983. During these years the weight of the above year classes only made up 6-10% of the catches.

According to the preliminary data from the USSR Young Fish Survey the yearclasses 1973 - 1976 are poor. In the International 0-group Survey the year classes 1981-1983 were recorded as strong and this corresponds to the results from the USSR Young Fish Surveys carried out in 1982-1984.

2.4 Age Composition (Tables 8 and 11)

Catch in numbers per age group for both S.marinus and S.mentella were adjusted to the revised total catch figures for 1981 and 1982.

For 1983, age composition data and age/length keys for S.marinus landings were available from the Federal Republic of Germany and USSR for Division IIa. The total age composition was calculated by applying the Federal Republic of Germany age composition to the total catch of all countries except for USSR (Table 8).

Age compositions of S.mentella for 1983 were available for the catches of the German Democratic Republic and the USSR. The sum of these were raised to the total landings in 1983 (Table 11). The age compositions of the S.mentella catches available in 1983 represent more than 99% of the total landings.

2.5 Mean Weight at Age (Tables 9 and 10)

For 1983, mean weights at age for S. mentella were available for the German Democratic Republic and the USSR landings. The mean weight at age for the age groups 6-10 in 1983 given by the USSR differed greatly from the ones used in previous assessments. These data were mostly based on samples taken in Sub-area I where only 4% of the USSR catch were taken, and they may therefore not be representative for the total landings. It

was decided to use the mean weight at age used in last years assessment for the age groups 6-10 and the USSR mean weight at age for the age groups 11-24+ (Table 9). The 1983 data were used for the catch projections. The SOP correction factor for these mean weights at age are given in Table 10, but none of them differs greatly from 1.0.

2.6 Proportion of Mature Fish at Age (Table 14)

Data were available from the German Democratic Republic and the USSR on S.mentella. These data differed greatly from the ones used in last years assessment, giving a much lower age at first maturity. These data were presented as averages over several years, and if used as presented, they would have created a discontinuity in the calculation of the spawning stock biomass. In order to utilize these data they need to be presented on a yearly basis for each sex separately. The Group therefore decided to use the maturation curve from last year's report (Table 14).

2.7 Assessment (Sebastes marinus)

As last year, no effort data were available for S.marinus on which to estimate fishing mortality in 1983.

It is therefore impossible for the Group to assess whether the trend in catches (Table 5) reflects a trend in stocksize or just a trend in fishing effort. The catches may also reflect the TAC set for the different years.

2.8 Assessment (Sebastes mentella)

2.8.1 Parameters Used (Figure 1)

As a first attempt fishing mortality in 1983 was estimated as 0.22 from the relationship of average F on the 8 to 19 year olds to total effort in USSR units given in last year's report and the total effort figure for 1983 (Table 6). From a VPA using this estimate and a recalculation of the linear regression between mean fishing mortality and total effort for the period 1965-1979 (Figure 1) a final estimate of $F(8-19)=0.23$ was derived.

Fishing mortality for the age groups 6-9 were calculated assuming an average recruitment level (1965-1979) at age 6 in 1980-1983. F-values for the age groups 10 and older were calculated according to the average exploitation pattern in the period 1974-1980.

Natural mortality of 0.10 was used as in previous assessments.

2.8.2 Fishing Mortality (Table 12, Figure 2)

Estimates of fishing mortality from the VPA are given in Table 12. The mean fishing mortalities on age groups 0-19 was low in the period 1965-1974, fluctuating around 0.08. An increase to an average level of 0.50 was recorded for the period 1975-1977, with a peak of 0.55 in 1976. From 1978 to 1982 the fishing mortality remained fairly stable at a level of 0.20. A decrease down to 0.23 was observed in 1983 (Figure 2).

However, since the minimum mesh size in the "Mentella box" was decreased from 125 mm in 1982 to 100 mm in 1983, the total effort and subsequently the fishing mortality in 1983 might have been underestimated. The Group was, however, unable to assess the magnitude of this possible bias (See also Section 2.2)

2.8.3 Stock Size (Table 13, Figure 2)

Estimates of stock size in numbers from the VPA, total stock biomass and spawning stock biomass are given in Table 13.

The result from the VPA (Figure 2) show that the total biomass increased steadily from about 300 000 tonnes in 1965 to about 1 million tonnes in 1975. It decreased continuously to about 670 000 tonnes by 1979 and remained fairly stable up to 1983.

The spawning stock biomass shows a similar increase from about 120 000 tonnes in 1965 to about 300 000 tonnes in 1975. By 1979 it decreased to about 130 000 tonnes and then increased to about 250 000 tonnes in 1983.

2.8.4 Yield per Recruit (Figure 3)

Due to the revision of the mean weight at age data on the older ages and a minor change in the exploitation pattern on the 6-9 years old the Group decided to recalculate yield per recruit. The results of these calculations are $F_{0.1} = 0.075$ and $F_{max} = 0.15$ when the last age group was considered as a plus group, $F_{0.1} = 0.11$ and $F_{max} = 0.18$ when the last age group was taken as a plus group. The input parameters used in these calculations are given in Table 14. The resulting two yield per recruit curves are given in Figure 3.

The estimated mean fishing mortality in 1983 of 0.23 is above the F_{max} level on both of the two yield per recruit curves.

2.8.5 Catch Projections (Table 14, Figure 4)

Based on the estimated stock size in the beginning of 1984, catch projections were made for 1985 and 1986, using the parameters in Table 14. Furthermore the average recruitment (1965 - 1979) of 437 millions at age 6 was applied in the projections 1984-1987.

For 1984 it was assumed that the TAC of 90 000 tonnes will be

taken. The fishing mortality required to achieve this catch is at a level of $F(8-19) = 0.21$.

The result from the catch projections are shown in Figure 4. The catch in 1985, total stock biomass and spawning stock biomass at the beginning of 1986 are plotted against fishing mortality in 1985.

In its terms of reference the Working Group was requested to provide projections of catch and stock size for 1986 and 1987 respectively, if meaningful. In view of the apparent stability of the total biomass and stock numbers in recent years the Working Group felt that a projection beyond 1985 could indicate likely catch levels for 1986 and their consequences on spawning stock biomass. However, the limited time available did not allow to cover all possible combinations of options for the two years in the projection for 1986(?). Therefore the options for 1986 are given under the assumption that the target fishing mortality for the management in 1985 will be maintained in 1986.

For selected values of fishing mortality in 1985 and 1986, the results are summarized in the text table below.

It can be seen that continuing fishing at the 1984 level of fishing mortality in 1985 and 1986 will give a slight increase in the total stock biomass and keep the spawning stock biomass nearly stable up to the beginning of 1987. Fishing at the $F_0.1$ or F_{max} level in 1985 and 1986 will give an increase in both total stock biomass and spawning stock biomass.

Management Options for 1985 and 1986

Weights in thousand tonnes

*) last age group assumed to be a plus group

3. REDFISH IN SUB-AREAS V AND XIV

3.1 Status of the Fisheries (Tables 15 - 18)

The total catch from the Irminger Sea redfish stock complex increased in 1981 from 146 000 tonnes to 229 000 tonnes in 1982 and decreased slightly to 225 000 tonnes in 1983. This rise in catch figures over the last two years compared with the years before, originated from catches in the new fishery, based on the stock of S.mentella type oceanic.

The total catch of redfish, excluding catch figures from the new fishery, decreased slightly from 169 000 tonnes in 1982 to 164 000 tonnes in 1983. The catches in Division Va increased by about 8 000 tonnes, whereas in Sub-areas XIV, the catches decreased by about 12 000 tonnes. In Division Vb, the catch was almost the same as in 1982.

In Division Va (Iceland), the Icelandic fleet increased the fishing effort in 1983, compared with 1982. This resulted in an increase in the Icelandic catch from 115 051 tonnes in 1982 to about 123 000 tonnes in 1983. The increase in the fishing effort on redfish was mainly due to restrictions in the cod fishery and reduced availability of cod in 1983. The fishery in the Rosengarten area was resumed in 1983 after 4-5 years with minor fishing in that area.

In Division Vb (Faroes), the catches increased slightly from 8 871 tonnes in 1982 to 9 200 tonnes in 1983, mainly due to an increase in the Faroese catches from 4 000 tonnes in 1982 to 4 600 tonnes in 1983, whereas the catch taken by the Federal Republic of Germany fleet decreased slightly by about 200 tonnes to 4 400 tonnes in 1983.

In Sub-area XIV (East Greenland), the total catch (excl. S.mentella type oceanic) increased by 12 000 tonnes from 42 815 tonnes in 1982 to 30 800 tonnes in 1983. The catches in the East Greenland waters were exclusively taken by the fleet of the Federal Republic of Germany. The reduction in the catch was mainly due to the reduction in the number of vessels participating in the fishery.

The fishery on the S.mentella type oceanic stock took place outside the 200 nm zone in Sub-areas XII and XIV, and the catches amounted to 60 581 tonnes in 1982 and about 60 000 tonnes in 1983. These catches are not included in the present assessments (See Section 3.7).

3.2 Recruitment of Redfish in the Irminger Sea

In 1983 0-group redfish were mainly distributed in the central region of the Irminger Sea, while the East Greenland shelf area, where the heaviest concentrations of 0-group redfish are usually observed, was almost devoid of redfish fry. Very few 0-group redfish were present in the Dohrnbank region as well as south of 60 N. In the Icelandic area, redfish fry were mainly

observed off the north coast of Iceland.

No areas with abundance in excess of 1 000 individuals per nm² were observed. The abundance index of 0-group redfish, 0.7×10^6 fish per nm² is the lowest on record since 1970. In general the 0-group redfish were smaller than previous years.

The year to year fluctuations in the abundance of 0-group redfish, as estimated in the surveys, are shown in the text table below.

Number of 0-group redfish x 10⁶ / nautical mile²

1970	8.6
1971	12.6
1972	31.1
1973	74.0
1974	23.6
1975	12.6
1976	5.8
1977	13.0
1978	6.5
1979	1.3
1980	3.0
1981	9.0
1982	2.7
1983	0.7

The analysis of redfish fry by species indicated that the proportion of S.marinus in 1983 amounted to 47%, 43% and 46% in 1980 to 1982. However, the proportions within the different regions in the Irminger Sea are very variable from year to year.

3.3 Splitting Catches into S.marinus and S.mentella(Tables 18-21)

In Division Va, the Icelandic catch was allocated to S.marinus and S.mentella components in proportions 69.8% to 30.2% based on observations of landings. The catches of Belgium, Norway and the Faroes are in accordance with their fisheries allocated to S.marinus.

In Division Vb the Federal Republic of Germany catch was S.mentella according to observations on landings. The proportions of S.marinus and S.mentella catches of the Faroe Islands were 66.52% and 33.48% respectively. These figures were derived from observations on landings. The estimated catch of France was allocated as reported last year, i.e., 76.54% S.marinus and 23.46% S.mentella.

In Sub-area XIV, the catch of the Federal Republic of Germany was allocated in the same proportions as observed in the landings, i.e., 50.68% and 49.32% for S.marinus and S.mentella, respectively.

3.4 Length and Age Compositions (Tables 22, 26)

Division Va

Length frequencies from the Icelandic catches in 1983 were available for both species and were used to calculate the length distribution of the catch in numbers for the respective species.

For S.marinus in Division Va, the Icelandic age/length key was combined with the age/length key used in 1983 for the younger and older age groups, since it did not cover all length frequencies. For S.mentella in Division Va, Icelandic data was available. These data were used to calculate the number at age.

Division Vb

Faroese data on length frequencies for both species were available for Division Vb; the Federal Republic of Germany age/length key was applied for S.mentella, whereas for S.marinus the combined Icelandic age/length key for Division Va was used to calculate the numbers at age.

Sub-area XIV

Federal Republic of Germany data on length composition of the 1983 catches as well as the corresponding age/length keys were available for both species, and used to calculate the length and age distributions of the total catch.

The combined age compositions of the total catches in Sub-areas V and XIV are given in Table 22 for S.marinus and in Table 26 for S.mentella.

3.5 Assessment of *Sebastes marinus*

3.5.1 Weight at Age (Table 25)

Comparison of the nominal catch in 1983 with the calculated catch using mean weights at age from the previous assessment (SOP-check) resulted in a deviation of 9%.

No new direct observations on mean weight at age in the catch were available. However, data on average weight per cm-group originating from an extensive sampling programme carried out by Iceland in 1979 covering commercial catches as well as research vessel catches have been used to calculate average weight per age group by means of an age/length key. The resulting data were very similar to those used previously as mean weights for the stock. The SOP-check showed differences of -3% and -1% for the years 1982 and 1983 respectively. Since the difference in 1981 was -6% as in the previous assessment the Working Group agreed to use the new data from 1982 onwards for both catch and stock (Table 25).

3.5.2 Proportions of Mature Fish at Age (Table 25)

Icelandic data on proportions of mature fish at age obtained in 1983 show only minor differences compared to those used in the previous assessments, and there was no reason for a revision.

3.5.3 VPA (Tables 23 and 24, Figure 5 and 6)

Catch per unit effort data from the Icelandic fishery have been used to calculate total effort in the redfish fishery in Sub-Areas V and XIV (see text table below). Total effort has been allocated to S.marinus and S.mentella according to their proportions in the catches.

Year	cpue kg/hr trawling*)	Total effort	<u>S.marinus</u> effort 1000 hours trawling	<u>S.mentella</u> effort
1978	1 034	63.7	46.2	17.5
1979	1 148	85.3	65.4	19.9
1980	1 180	94.4	74.7	22.7
1981	1 168	124.7	86.7	38.0
1982	1 146	147.2	107.5	39.7
1983	1 062	155.1	100.1	55.0

*) for landings where redfish make up 70% or more.

The resulting effort figures for S.marinus have been used to estimate fishing mortality for that species in 1983. This approach was accepted by the Working Group as the cpue figures cover more than 2/3 of the total S.marinus catch.

The calculation was done in the following way:

An initial VPA was performed with the average fishing mortality on age groups 14 to 23 derived from the catch projection in the 1983 assessment corresponding to the catch of 106 300 tonnes in 1983, i.e. 0.275. From a regression based on the average $F(14-23)$ and the effort for the years 1978 - 1982 mean F corresponding to the effort for 1983 was estimated as 0.286 (see Figure 5). The nature of the data and the method used made a finer tuning of the estimate not very meaningful and therefore an average $F(14-23)$ of 0.28 was the agreed estimate for 1983.

It was indicated in the discussion that a part of the Icelandic fishery for redfish since 1978 had shifted to fishing grounds which have not been fished regularly by Icelandic vessels. Therefore the respective Icelandic fishermen have gone through some learning processes particularly in 1978 and 1979 until they became fully familiar with these fishing grounds. For this reason it is quite likely that the average catch per unit effort could have been higher in those years. As a consequence the effort in 1978-79 might be slightly overestimated and hence

fishing mortality estimates based on these data are on the conservative side and not likely to be underestimated.

The exploitation pattern as revised in the 1983 assessment for age groups 10 and older was inspected on the basis of the average F per age group for 1975-79 but no reason for a further revision was indicated.

In the VPA the numbers at age 7 in the stock appeared to be unrealistically high for the years 1980 to 1983. Small changes in the fourth decimal of the F-values on age groups 7-10 in 1983 result in large changes in the stock numbers of the respective year classes. Therefore, average recruitment over 1975-79 was used to calibrate fishing mortality on age groups 7 to 10 in 1983 and to adjust the exploitation pattern accordingly. The catch projection for 1985 is only marginally affected by this approach since both F and mean weights are small on these age groups; however the total biomass estimates might be somewhat biased.

As in previous assessments natural mortality of 0.10 was used.

The results of the VPA (Tables 23, 24 and Figure 6) show an increasing trend of fishing mortality in recent years following the trend in catches with a slight reduction in the 1983 estimate. Total biomass (7+) increased continuously from a stable level of about 0.8 million tonnes in the 1967-1972 period to about 1.2 million tonnes by 1979 and remained at this level. Although some stability might be artificially introduced by using average recruitment from 1980 onwards.

3.5.4 Yield per Recruit Curve (Table 25, Figure 7)

A new Y/R curve was calculated using the revised average weight at age figures and with the oldest age group as plus-group. F_{0.1} is 0.03 as in the previous assessment. The curve has a maximum at F of 0.05.

In view of the very low fishing mortality associated with these reference points the Y/R curve was also calculated with the oldest age group not as a plus group. Under this assumption the reference points F_{0.1} and F_{max} are 0.05 and 0.10 respectively.

3.5.5 Catch Projection and Management Options (Table 25, Figure 8)

In its terms of reference the Working Group was requested to extend the usual projection of catch and stock size for the following year (i.e. 1985 and 1986 respectively) to 1986 and 1987 respectively if meaningful. In view of the apparent stability of the total biomass and stock numbers in recent years the Working Group felt that a projection beyond 1985 could indicate likely catch levels for 1986 and their consequences on spawning stock biomass. However, the limited time available did not allow to cover all possible combinations of options for the two years in the projection for 1986(7). Therefore the options for 1986 are given under the condition

that the target fishing mortality for the management in 1985 will be maintained in 1986.

The basic data for the projection of catches in 1985(6) and for the stock size at the beginning of 1986(7) are given in Table 25. Average recruitment of 7 year old fish over the period, i.e. 350 millions, was used in the catch projection.

In the absence of any indication of the likely total catch level of *S.marinus* from the Irminger Sea stock complex in 1984, a catch of 110 000 tonnes was assumed to be taken in that year. The results of catch projections are given in Figure 8 and some management options are given in the text table below.

Fishing at the 1983 level of exploitation in 1985 and 1986 would allow to maintain the present catch level and would also maintain the spawning stock biomass at its stable level around 420 000 tonnes. The high level of total biomass would be kept at about the present level over that period.

The options associated with reference points on the Y/R curve result in unrealistically low catch levels which have never been recorded in the fishery.

Note on the option table:

The options in the text table below refer to a catch level in 1984 of 110 000 tonnes. The weights given in the table (and in Figure 8) can be corrected by adding (if the catch is below 110 000 tonnes) or subtracting (if the catch is higher than 110 000 tonnes) the following percentages for each 10 000 tonnes deviation:

Catch:	3.6 %
Spawning stock biomass:	2.3 %
Total biomass (7+):	1.1 %

3.6 Assessment of *Sebastes mentella* (Tables 26 - 28, Figure 9)

The assessment of *S. marinus* was based on the estimated effort for this species in the Icelandic fishery. An attempt was made to apply the same approach to *S. mentella* (see Section 3.5.3). The intercept of the regression line (see Figure 9) was relatively large and accounted for about half the fishing mortality estimated from the line. Furthermore, the estimate of F for 1983 had to be made by extrapolation beyond the points used in calculating the regression.

Therefore, the Working Group was not able to assess the *S. mentella* stock with sufficient reliability. The VPA-tables and the corresponding regression are given in Tables 26 to 28 and in Figure 9 for illustration purposes.

3.7 Note on the *Mentella* Type Oceanic Stock in Sub-areas V - XIV

At its last meeting the Working Group urged that relevant data on this stock should be provided to make an assessment of this stock possible in the future.

The Working Group appreciated that USSR data on this stock were submitted to this years meeting. The documents include data from the fishery in 1982 and 1983 and will be presented at the ICES Statutory Meeting in 1984. Some Icelandic data were also available. The time series, however, is too short to allow an assessment of this stock to be made at present.

3.8 Historic Catch Levels (Figure 10)

The total annual catch of redfish *S. marinus* and *S. mentella* in Sub-area V and XIV is shown in Figure 10 for the years 1949-1983.

The great fluctuations over longer periods are associated with rather complex interaction in changes of effort and availability of redfish in the area. In the fifties the very high catches were maintained by discoveries of new fishing grounds in Icelandic and East Greenland waters. In the late fifties and early sixties a great part of the effort was removed from Sub-Areas V and XIV because of reduced availability of redfish in the Irminger Sea region as well as good fishing opportunities in other areas.

The increase in catch in the sixties was associated with the decline in (mainly) the Arctic cod fisheries, causing increased effort in the Irminger Sea region. There was a great decline in the catches in the late sixties until late seventies, in spite of increased efficiency of the fleet during that period. One reason was again the diversion of fishing effort, mainly of freezer trawlers of the Federal Republic of Germany, to the fishery on cod and also herring on Georges Bank and less availability of redfish in the Irminger Sea region.

The short-time increase in 1975-1976 was due to the USSR catch of small redfish at East Greenland. The extreme decline in the late seventies is *inter alia* associated with the extention of the fishing zone at Iceland. Since then there has been a great increase in effort by the Icelandic fleet at least (see Section 3.1).

Considering this complex situation without reliable information on total effort until in the later years, the Working Group feels that little can be said about the sustained yield on the basis of the historical catches.

4. GREENLAND HALIBUT IN SUB-AREAS I AND II

4.1 Status of the Fisheries (Tables 29 - 32)

The nominal catches by country for Sub-area I and Divisions IIa and IIb are given in Tables 29, 30 and 31. In Table 32 the catches are summarized for Sub-areas I and II. The total catch in 1982 was 16 733 tonnes, i.e. 39% above the TAC of 12 000 tonnes for that year. In 1983, the total catch was 22 342 tonnes according to the preliminary catch figures, i.e. 5 342 tonnes (31%) above the TAC of 17 000 tonnes.

4.2 Catch per Unit Effort and Effort Data (Table 33)

The cpue data available to this years meeting was the data from USSR sidetrawlers (1965 - 1983) and the USSR sterntrawlers (1980 - 1983). The previously used cpue-series from German Democratic Republic trawlers stops in 1980 due to a change in fishing strategy, and it has therefore not been included in this year's assessment.

A new series of cpue data from the Norwegian freshfish trawlers was made available to this meeting. The difference being that while the old series only utilized the data from the period September to November in three main fishing areas as described in CM 1981/6:7, the present series utilized all the data from the directed fishery for Greenland halibut by the freshfish trawlers, i.e. during the whole year and in all of the relevant areas within Sub-areas I and II.

The series given in previous reports was calculated by weightting the observations by effort. The series given in the present report is calculated by utilizing the statistical package GLIM (NAG). A linear model is used:

$$\log(\text{Catch})_{i,j,k} = \log(Y)_i + \log(M)_j + \log(A)_k + \log(\text{Effort})_{i,j,k}$$

Y is the catch per unit effort index for year i after it has been corrected for the changes in availability due to seasonal effects (Month j) and areas affects (Area k, which represents statistical areas as used in the Norwegian fishery). Y, M and A are treated as factors (qualitative covariates). The cpue index (Y) was standardized relative to the Norwegian statistical area 39 (south west of Bear Island) in October, which is an important fishing area during the main season in the autumn. It was assumed that log(Catch) is normally distributed. By this analysis one may correct for possible redistribution of the fleet, either between areas or parts of the year, that may affect the total cpue series.

The USSR and the Norwegian cpue data (Table 33) follow each other closely, the latter on the average being 13% larger for the period 1973-1983. The cpue series used in the assessment was taken as the mean values of the two series (Table 33), and

from this series the total effort and the catch per hour trawling of 7 years and older was calculated (Table 33).

4.3 Mean Weights (Tables 34 and 35)

For the years 1970 - 1981 the group accepted the series used in last years assessment. The values for 1982 and 1983 were estimated from the biological sampling done by USSR, GDR and Norway. The different national series were weighted by the national catches they represent. The results are given in Table 34. With these mean weights the SOP differs by 1.7% and 4.8% from the nominal catches in 1982 and 1983 respectively (Table 35). This was considered to be satisfactory close.

4.4 VPA

4.4.1 Age Compositions (Table 36)

The age compositions for 1982 and 1983 (Table 36) were estimated utilizing the available catch at age data from the GDR fishery (1983), the Norwegian fishery (1982-1983) and the USSR fishery (1982-1983). The age compositions available accounted for 93% and 99% of the catches in 1982 and 1983 respectively.

The group noted, however, that due to the early date for this Working Group meeeting, and the fact that the main fishery for Greenland halibut in the Barents Sea takes place in the autumn, it had not been possible to utilize all of the biological material collected in 1983. This also limits the amount of data that could be utilized in estimating the cpue for the commercial fleet in 1983.

4.4.2 Input Parameters and Results (Tables 37-38, Figures 11-14)

As in previous reports, a constant natural mortality of 0.15 was used, and the unweighted average fishing mortality on the 7 to 11 year olds was selected as the standard.

The relation used in assessing the input Fs on age groups 6 and older, were a regression of the F(7-11) against total effort (Figure 11), and setting the exploitation pattern on these age groups close to the average for 1970-1979.

For the age groups 3 to 5 the input Fs were selected on the basis that the estimated number of 3 year olds in the stock in the last three years (1981 - 1983) become close to the average of the 3 year olds in the period 1970 - 1979 (32.8 millions).

On the basis of the Figures 11 to 13 this was found to be an acceptable procedure. The results of the VPA are given in Tables 37 and 38, and shown in Figure 14.

4.5 Yield per Recruit (Figure 15)

The new exploitation pattern and the mean weights used for 1983 only gave about 10% relative change in the estimates of the F_{0.1} and F_{max} values. While the values of yield per recruit were somewhat higher at the reference points, the estimated average recruitment was somewhat lower than the one used in last year's assessment, the product being almost unchanged. The Group therefore saw no reason to change the reference values of F_{0.1} and F_{max}, which has remained unchanged since 1982. The Y/R and the SSB/R curves are shown in Figure 15.

The yield and the spawning stock under equilibrium conditions, as given in last year's report, are given with some additions in the text table below. The recruitment being constant at the same level as in the 1970's. As for the values of F_{0.1} and F_{max} these are to be considered as longterm reference values.

F(7-11)	Sustainable Yield (tonnes)	Spawning stock biomass (SSB)(tonnes)
1) F _{0.1} = 0.12	23 800	112 000
1) F _{max} = 0.20	25 400	75 000
1) F ₈₃ = 0.27	25 100	51 000
2) F _{0.1} = 0.07	24 700	200 000
2) F _{max} = 0.14	26 700	110 000
2) F ₈₃ = 0.27	25 300	51 000

- 1) The oldest age group (16) is not a plus group.
- 2) The oldest age group (16+) is a plus group.

4.6 Catch Projections (Table 39, Figure 16)

The Working Group has sufficient confidence in the assessment that it warrants to make projection for two years (however, see also comments in Section 8).

Catch projections for 1985 and 1986 were made using the parameters given in Table 39. For each management option in 1985 the prognosis was carried forward to 1987 with the catch option in 1986 being equal to the one in 1985.

The catch in 1985 and 1986 for seven alternative fishing mortalities, the resulting stock biomass (3 years and older), and the spawning stock biomass (9 years and older) in 1986 and 1987 are given in the text table below. The same parameters for 1985 and 1986, as a function of the fishing mortality in 1985, are shown in Figure 16.

Looking at both the cpue (Table 33) and the VPA results (Figure 14), the stock appears to have decreased from 1965 up to about 1978. Since that time, an increasing trend seems to have occurred. Except for one, all the options for 1985 and 1986 given in the text table above, implies that the total stock and the spawning stock will continue to increase up to 1987. However, if the fishing mortality in 1985 and 1986 will be at the 1983 level, the prognosis predicts a stable situation or a slight downward trend in the total stock and the spawning stock in the period 1985-87.

5. GREENLAND HALIBUT IN SUB-AREAS V AND XIV

5.1 Status of Fisheries (Tables 40 - 43)

The total nominal catch figures by country for the Divisions Va and Vb, Sub-area XIV, and Sub-areas V and XIV combined, are presented in Tables 40 - 43 for the years 1974 to 1983. During this period, the total catch ranged from 6 045 tonnes (1976) to 36 283 tonnes (1974). Of the total catch of 30 560 tonnes in 1983 93% was taken by Icelandic vessels. The catches were almost exclusively taken by otter trawl with only a minor proportion of the Icelandic catch taken by longliners.

5.2 Effort and Catch per Unit Effort (Table 44)

Catch per unit effort data from Icelandic trawlers were available for the period 1978-1983 in the months January to August. These data were combined with the same statistical method that was used to analyse the data on catch and effort by Norwegian freshfish trawlers in the Barents Sea (Section 4.2). The only difference being that the factor accounting for area was not taken into account, as the basic data for the Icelandic trawlers were given for one area only.

After leaving the spawning area on the continental slopes off West Iceland in the last half of April and May, the Greenland halibut concentrates along a cold water front further north. This is the area where the trawlers have taken most of their Greenland halibut catches in recent years. However, the quality of the fish in these catches have been rather unsuitable for human consumption and therefore catches had to be partly processed by fishmeal plants. For this reason it was totally prohibited to fish in this area in April and May during the 1983 season. As a result of this the trawlers had to fish in other areas with lower concentrations of Greenland halibut.

Therefore, the catch and effort data for April and May 1983 were excluded from the analysis above. The resulting cpue series, which is standardized relative to May, are given in Table 44.

5.3 Weight at Age (Table 45)

The mean weights in 1983 were derived from the same data that were used to construct the Icelandic age/length key.

5.4 Proportion of mature fish at age (Table 46)

The proportion mature at age in the 1983 catch was estimated from the Icelandic biological sampling program.

5.5 VPA

5.5.1 Age Composition (Table 47)

The catch in number per age for 1982 was adjusted according to the final catch data. For the year 1983, length compositions and age/length keys were available from Division Va (for Iceland) and Sub-area XIV (for the Federal Republic of Germany). As the age/length relation in both sets of data was almost identical and the catch in Sub-area XIV was very small, the Icelandic data were used to calculate the age composition for the total catch from Sub-areas V and XIV (Table 47).

5.5.2 Input Parameters and Results (Tables 48-49, Figures 17-18)

As in previous years the natural mortality was assumed to be 0.15. The mean fishing mortality on the age groups 8-13 in 1983 was estimated from the line through point of the mean values of $F(8-13)$ and total effort in the years 1978 to 1982, and the origin (Figure 17). The exploitation pattern in 1983 was taken to be close to the average for 1978 - 82. The input F on the 4 year olds in 1983 was, however, slightly adjusted in order to generate a recruitment at age 4 close to the mean of the years 1975-1979.

The results of the VPA are given in the Tables 48 and 49, and Figure 18. The total stock biomass staid almost constant at about 260 000 tonnes in 1982 and 1983. The spawning stock biomass shows a slightly decreasing trend from 97 000 tonnes in 1980 to about 87 000 tonnes in 1983.

5.6 Yield per Recruit (Figure 19)

The yield and spawning stock per recruit curves as given in last year's report, are shown in Figure 19. This curve has a F0.1 point of 0.14. There is no maximum on the yield per recruit curve within a reasonable range of fishing mortality.

5.7 Catch Projection (Table 50, Figure 20)

Catch projection for the years 1985 and 1986 were made, using the parameters given in Table 50. For the catch projection it was assumed that the total catches in 1984 will be 32 000 tonnes. Projected catches in 1985 and the corresponding total biomass and spawning stock biomass at the beginning of 1986 are plotted against the mean F in 1985 in Figure 20.

For a selection of alternative fishing mortalities in 1985 and 1986, the results are summarized in the text table below. In these options the F s in 1986 remain unchanged from the ones in 1985.

Management Options for 1985 and 1986

			0.1				0.14	1	17		263	104	1	19	297	115

Weights in thousand tonnes

*) last age group (18) assumed to be a plus group

With a fishing mortality of 0.21 in 1985, which equals F0.1 when the last age group is a plus group, the total stock and the spawning stock would be allowed to increase slightly from 1984 to 1987, and the catch would be at 25 000 tonnes.

However, the Working Group considered the present prognosis to be subject to more uncertainty compared to the other stocks assessed by the Working Group. Therefore, the prediction for 1986 should be treated with the appropriate caution.

6. THE "Mentella BOX"

6.1 The Distribution of Cod

The material available on the distribution of cod in and around the "Mentella box" was a paper by L.M. Shestova and E.G. Lukmanov (ICES C.M.1983/G:23) and the 1983 report of the Arctic Fisheries Working Group (ICES C.M. 1984/Assess:3). This limited material suggested that bycatch of cod in the directed fishery for redfish in the "Mentella box" might only marginally affect the cod stock.

6.2 Optimum Mesh Size

A document by K.G. Konstantinov, V.G. Kovalenko, L.S. Lugovaya, E.G. Lukmanov, K.N. Nikeshin and V.L. Tretyak (ICES C.M. 1983/B:13) was presented which deals with the problem of optimum mesh size in the redfish fishery. For these evaluations there are several critical parameters.

One very important parameter for the calculation of maximum yield per recruit at different size at first capture is the natural mortality. Values of it used ranges from 0.10, as used by this Working Group, to 0.25, as used by V.A. Chekhova, K.G. Konstantinov and I.S. Shafran 1977 (ICNAF Res.doc. 77/VI/3) for younger ages. In order to get a better idea how the natural mortality may change with age and length, detailed material on predation on redfish by other species should be made available.

Another parameter is the relation between the spawning stock and recruitment. Lower mesh sizes would decrease the recruitment to and hence the size of the spawning stock, and might affect future recruitment and the long term yield. In order to improve our understanding of this relationship we need better estimates of the spawning stock and the recruitment. This requires further studies on the maturation process as well as good age samples of the catch and improved young fish surveys.

The escapement from the trawl is a futher problem. It is known that when fishing for redfish the trawl easily gets clogged and thereby drastically reduces its selectivity. This is particulary important when the catches are large. This means that in experiments for determining the selectivity of the trawls it may be crucial that the duration of the tows are similar to those in a commercial fishery.

It is also known from experiments that increased mesh size in the trawl may increase the filtering capacity of the trawl which may result in higher catches of larger specimens. This would to some extent reduce the calculated immediate losses due to an increase in the mesh size. Existing data should be analysed in terms of cpue to see if this phenomenon does occur.

The Group considers that the existing material should be fully analysed in order to address the problems above and thereby giving a better basis for an advice on optimum mesh size.

7. REDFISH AGE-READING WORKSHOP

The Group considered the findings of the Redfish Age-Reading Workshop (CM 1984/G:2) which critically reviewed the age validation procedures presently used. The technique of comparisons between different structures (otoliths and scales) from the same fish is shown to yield valid comparisons. The results of the present study indicate that no revision of techniques for ageing redfish presently used in the North-East Atlantic is required.

8. TIMING AND THE DURATION OF THE WORKING GROUP MEETING

For some stocks the main fishery takes part at the end of the year, and it may only be possible to use a limited part of the data that subsequently will become available, e.g. Greenland halibut in Sub-areas I and II (see Section 4.4 above). This implies that the expected quality of the prognosis is below what may otherwise have been the case. This has some bearing on the considerations of the possibilities for making sufficient reliable assessments for two years ahead (see ii) in terms of reference in Section 1.2).

The number of days allocated to the Working Group, i.e. 6 days including a Sunday, and the last being a Monday, implied that the typing of the first draft of the report had to be done by the members of the Working Group over the weekend. The Working Group thus had to work on a severe time schedule, and decided to give priority to the first three items on the terms of reference (Section 1.2).

Therefore, item iv) in the terms of reference was only briefly considered. In general it was felt that the effects on the evaluation of the prospects of the stocks concerned, from changes in mean weights and maturity data are relatively small. Although this may warrant a closer look on these problems at the next meeting of the Working Group, when it hopefully will have more working days allocated for its work.

Concerning the general request to the Working Groups for a review of the the present state of knowledge on growth rates and retention lengths for the different stocks (ICES C.M. 1983/Assess:22) and the examination of the log-residuals of the catch at age (ICES C.M. 1983/Assess:22 Addendum), the Working Group had, alas, to defer this to a later meeting.

Recruitment at age 3 = 35.9 million for 1984-87.

Figure 1. Severe mental illness in Divisions IIIa and IIb.
Relation of mean fighting mortality (age 0-19) to
total effort (hours' travelling $\times 10^{-3}$) in
USAF Bases (19).

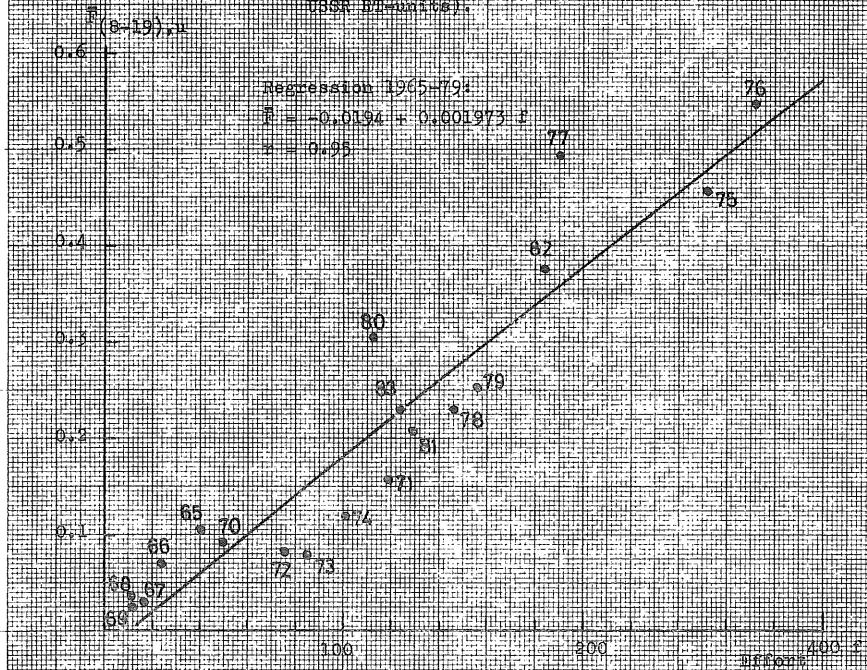

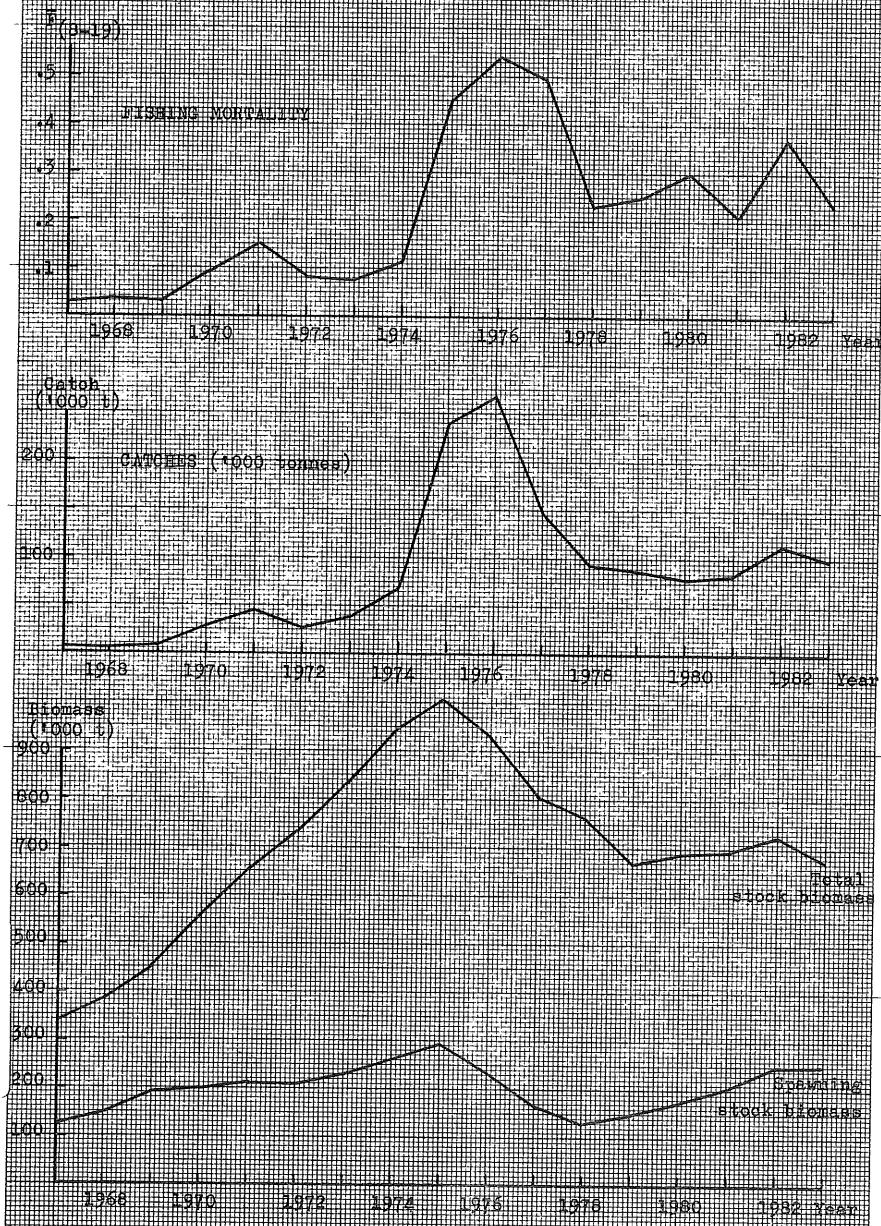

Figure 24. Subspecies merluccius or *Merluccius* *lao* and *lao*.
The fishing mortality, catch and development of
the stock from 1967-83.

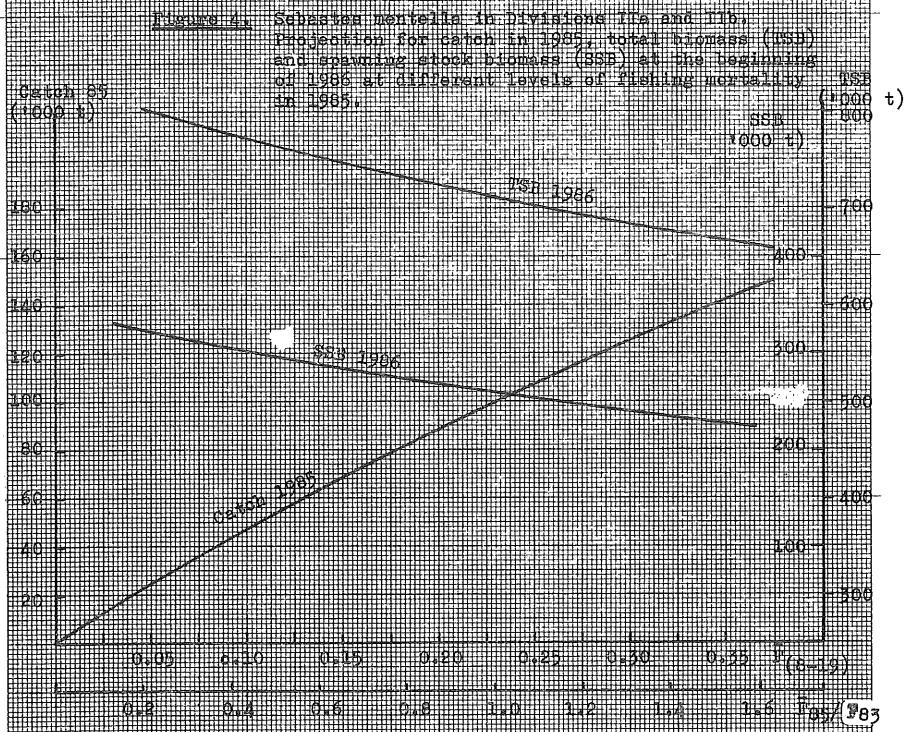

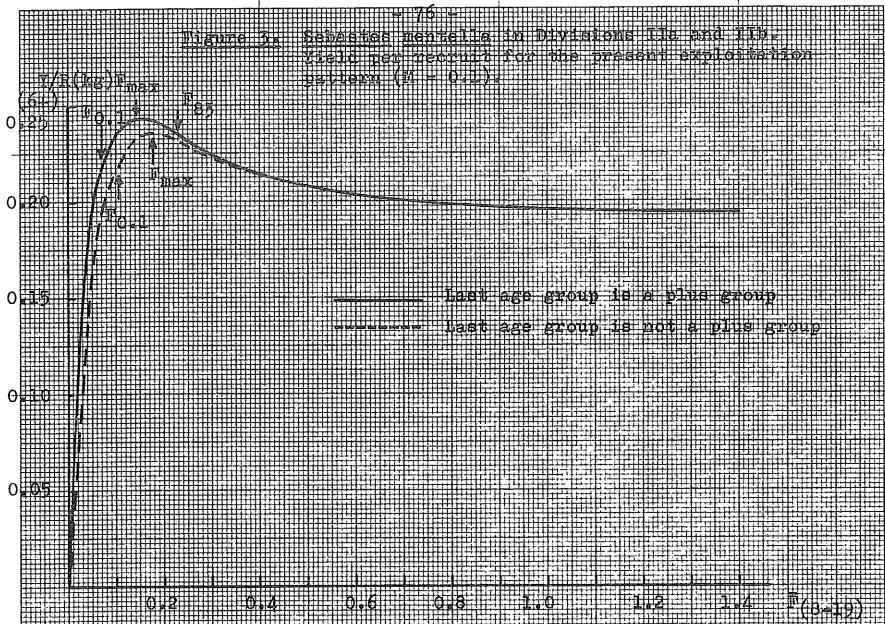

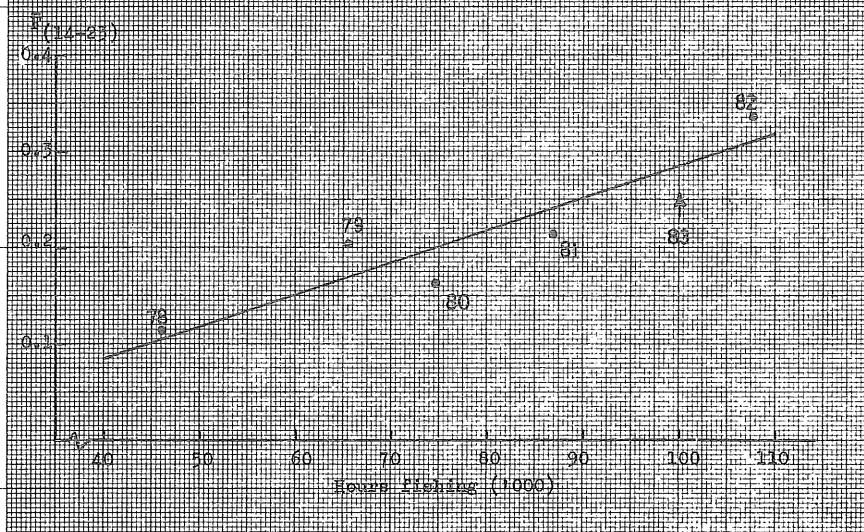

Figure 5. Seabird mortality in S10 areas V and XW
 Relation of mean estimated mortality (age 14-23)
 to total effort.

Hours fishing ('000)	1978	1979	1980	1981	1982	1983
	46.2	65.4	74.7	86.7	107.5	100.1

$$\begin{aligned} \bar{F}_{(14-23)} \text{ from VPA with } & 0.112 & 0.205 & 0.161 & 0.214 & 0.337 & 0.275 \\ \bar{F}_{(14-23)} = 0.275^1) & & & & & & \\ \text{in 1983} & & & & & & \end{aligned}$$

$$y = -0.050 + 0.003x \quad r = 0.92 \quad \rightarrow \quad 0.286$$

1) Corresponding to a catch of 106 300 tonnes in 1983.

Figures 15 & 16. Substrates measured during 1970-71 and 1971-72
The Canning Divisional Fishery Board Report
of 1972-1973 p. 222 & 223.

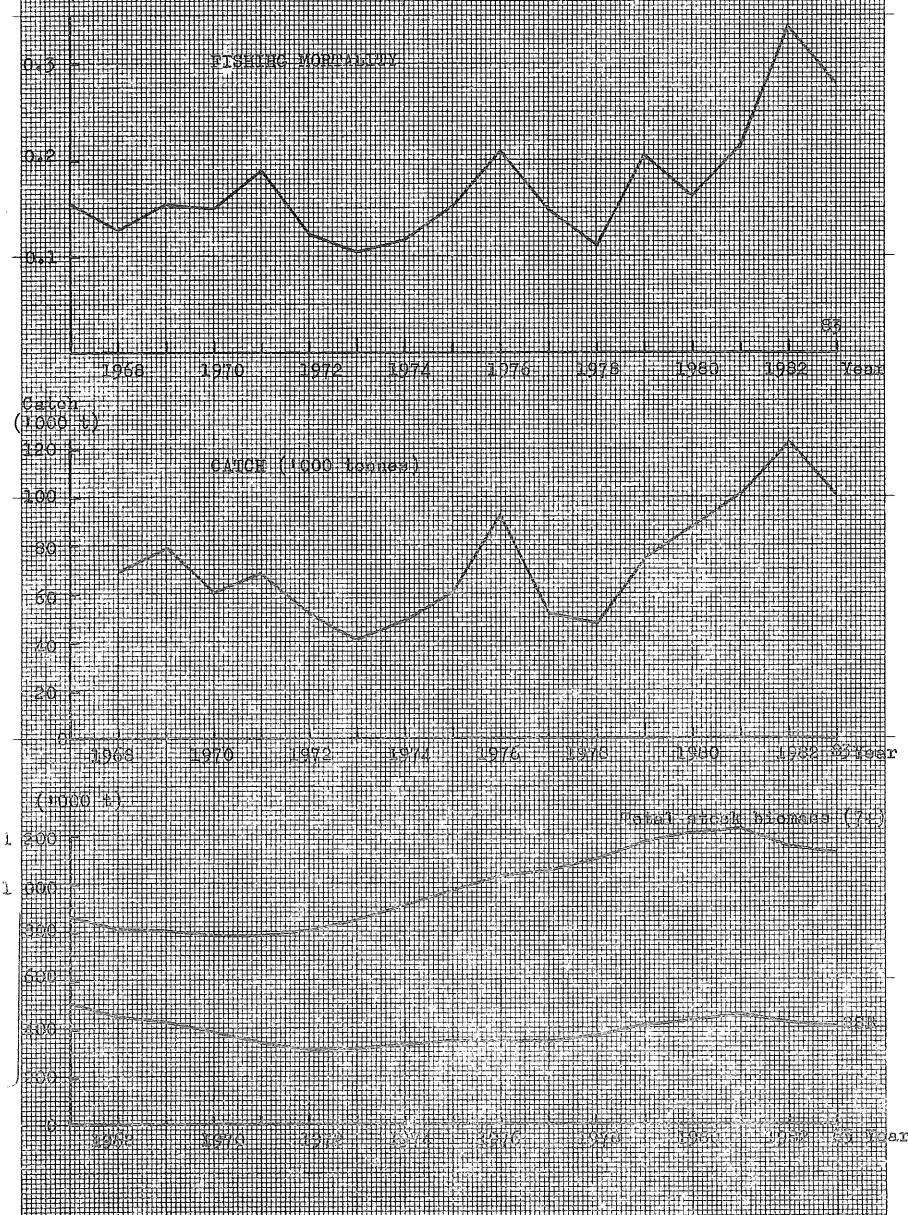

Figure 1. Seabass densities in Sub-area V and XIV
yield per hectare.

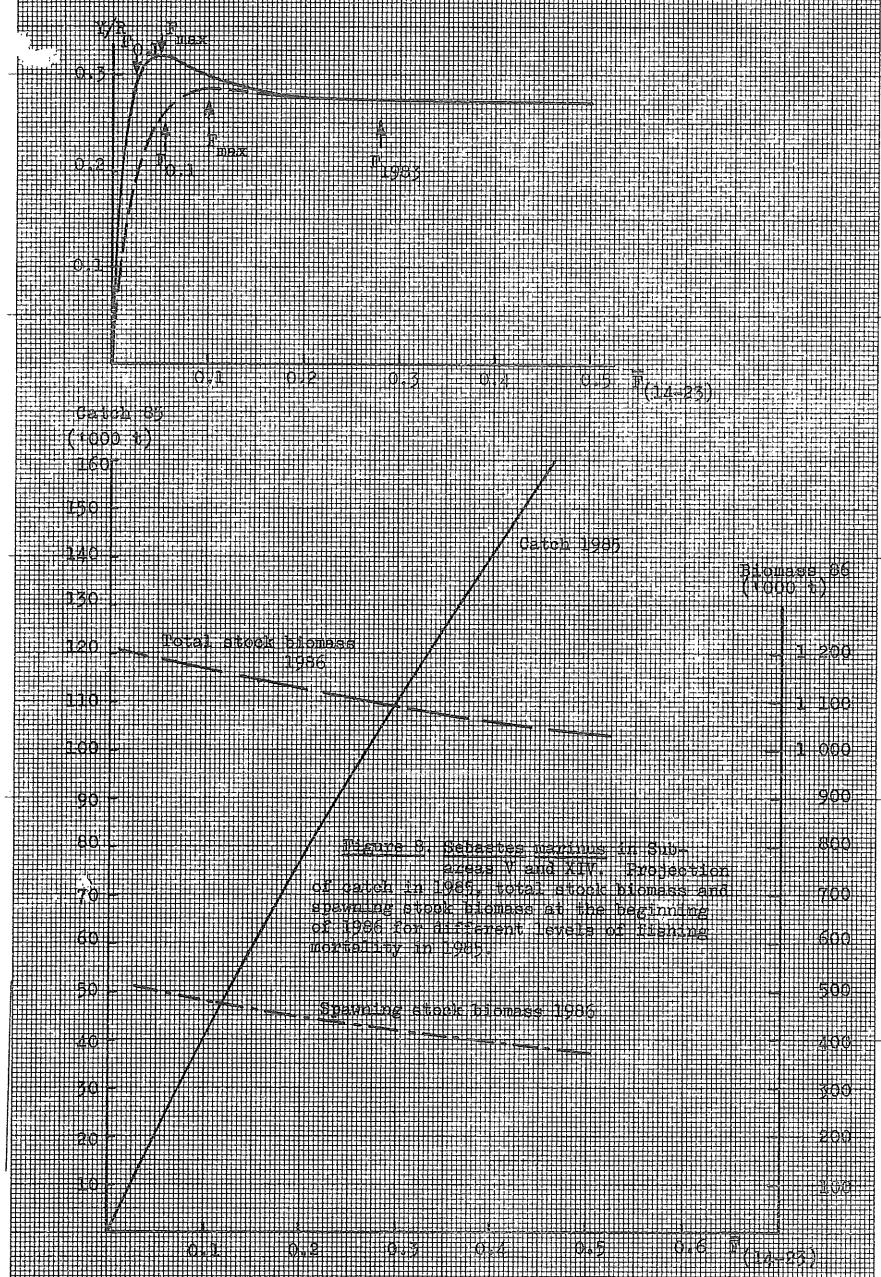

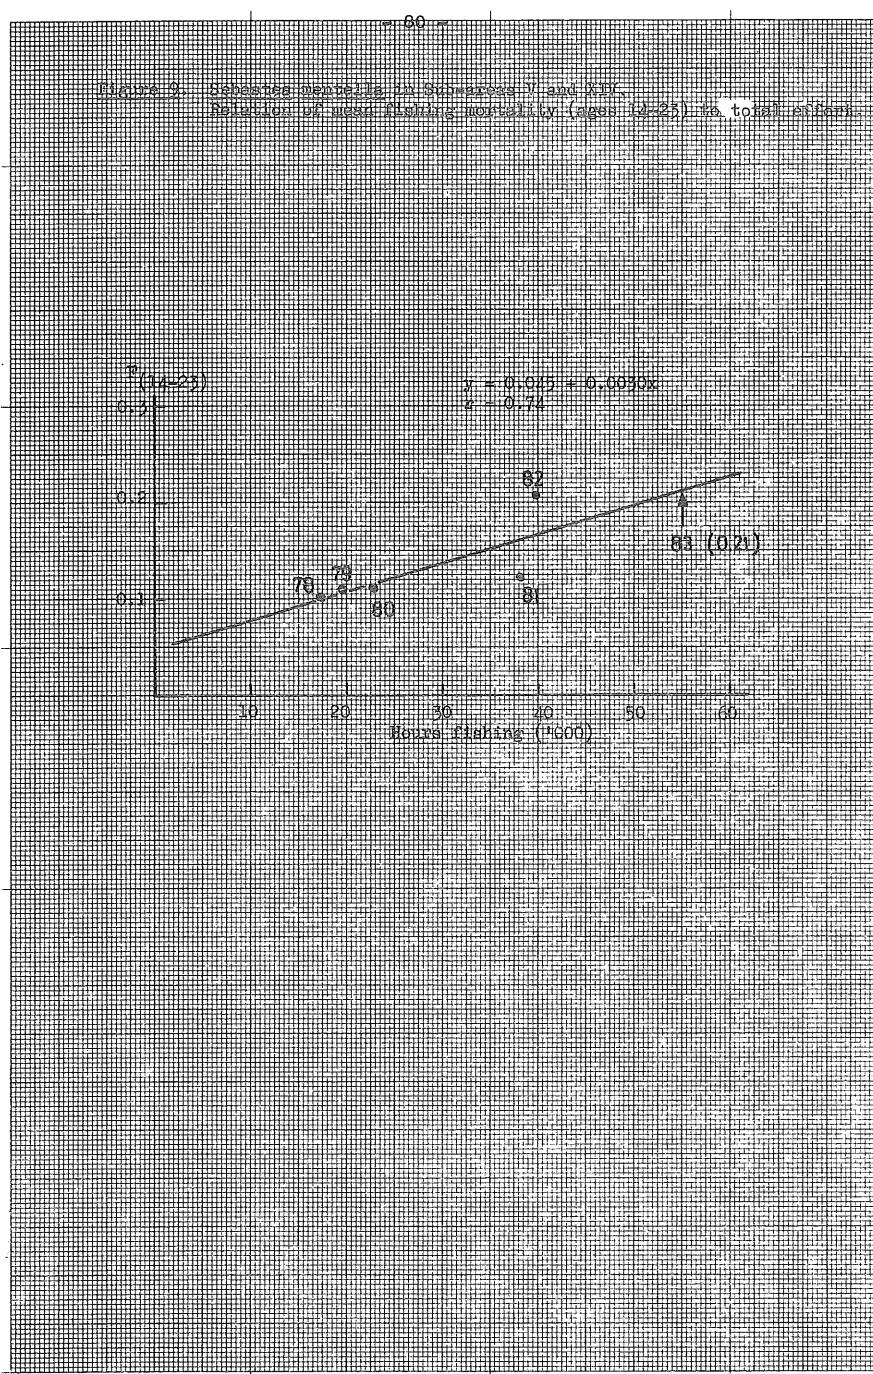

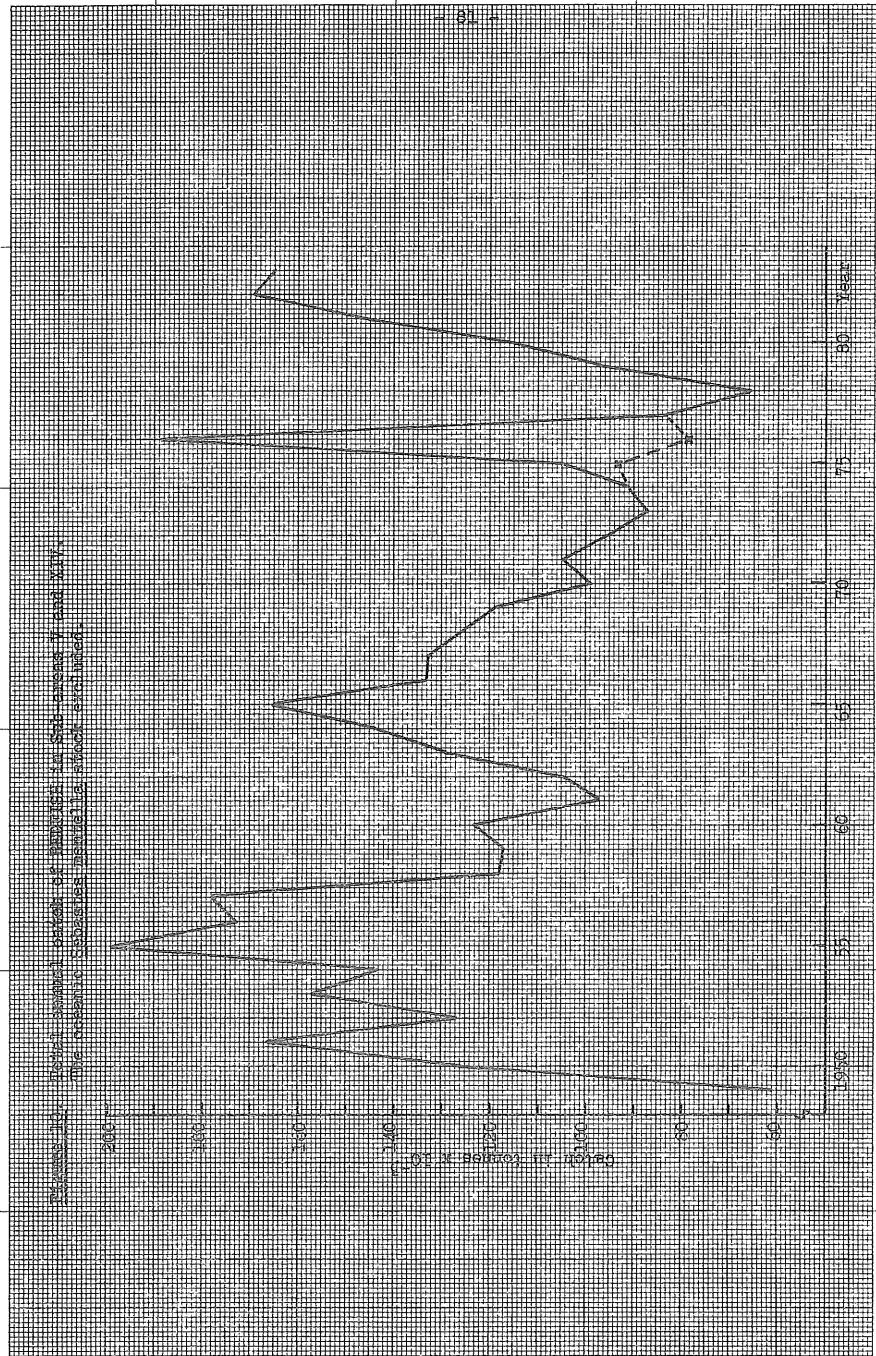

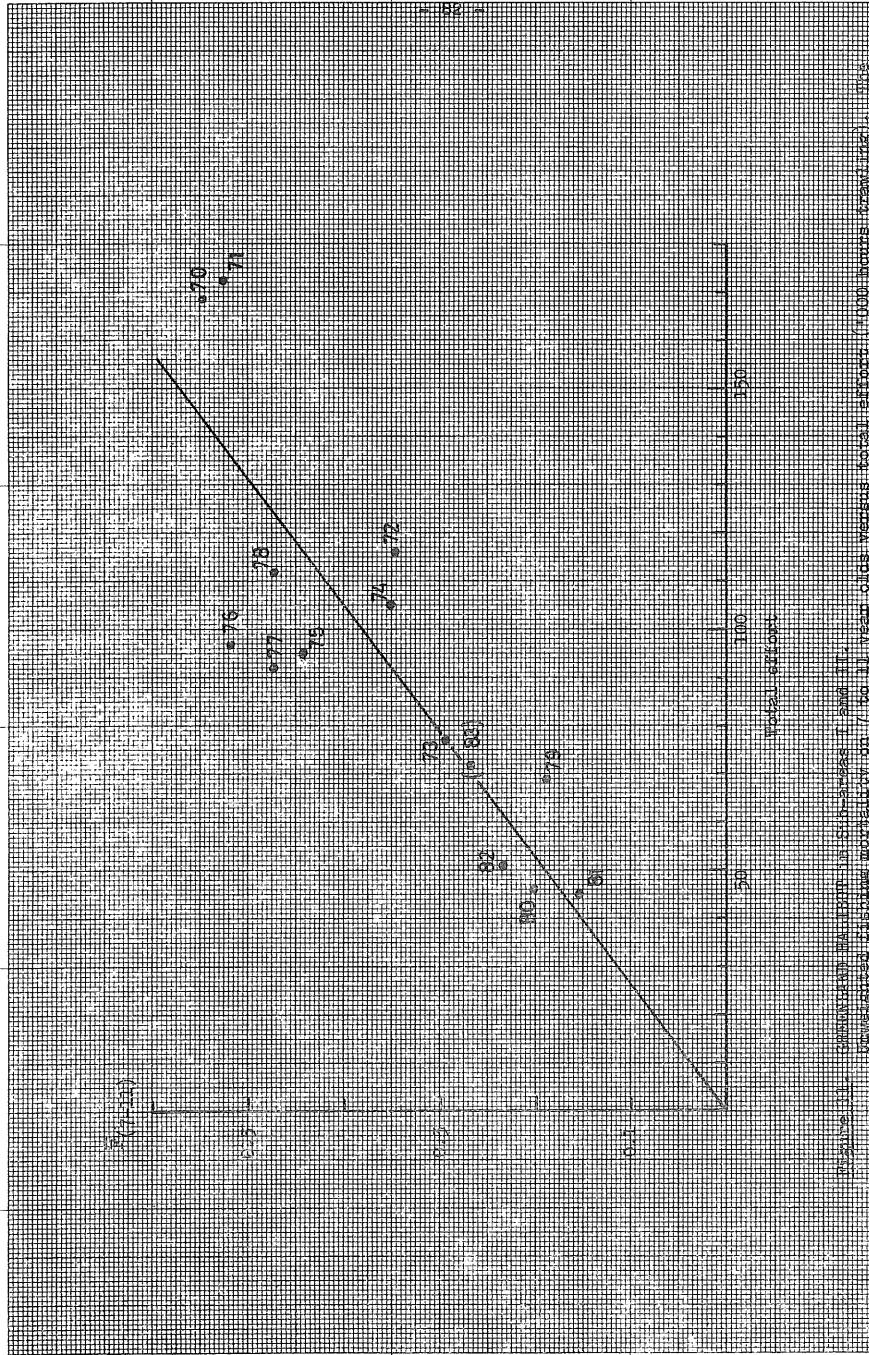

Figure 9. Seabream mortality in Subseries V and X-IV
Relation of mean fishing mortality (ages 19-23) to total length.

line is forced through the origin and the average for 1970-82.

FIGURE 12. CATCHABILITY MUSEUM BY SEASONS 7 AND 11.
Estimates of 1-year old fish from the mid-season trawl
catch (11 months) per unit effort (long gear 100 m). The
line is positioned between the optimum and the average (1970-82).

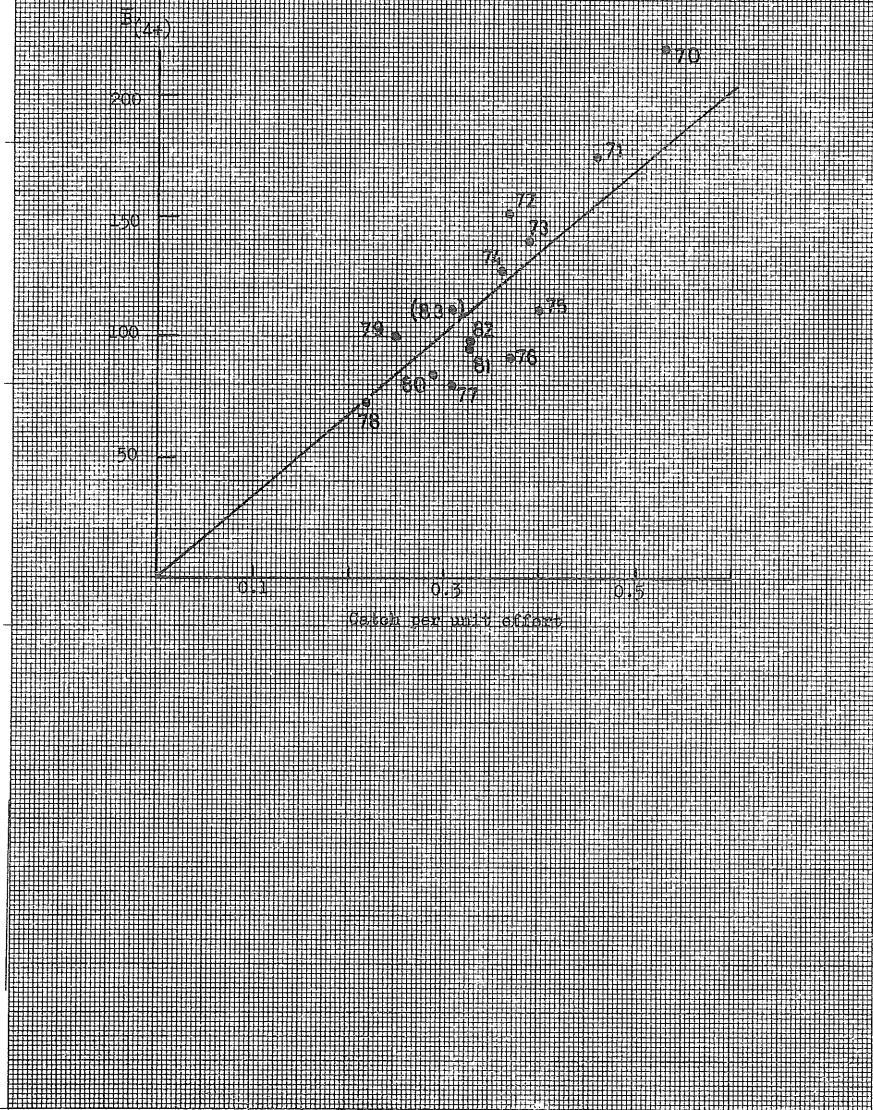

Figure 3.2 Catching efficiency in Sub-area I and II.

Catches of 7 years and older in the mid-section were
set out (in tonnes) of 7 years and older fish per hour
trawling. The line is forced through the origin and the
equation $y = 3.970 \cdot x^{0.70}$.

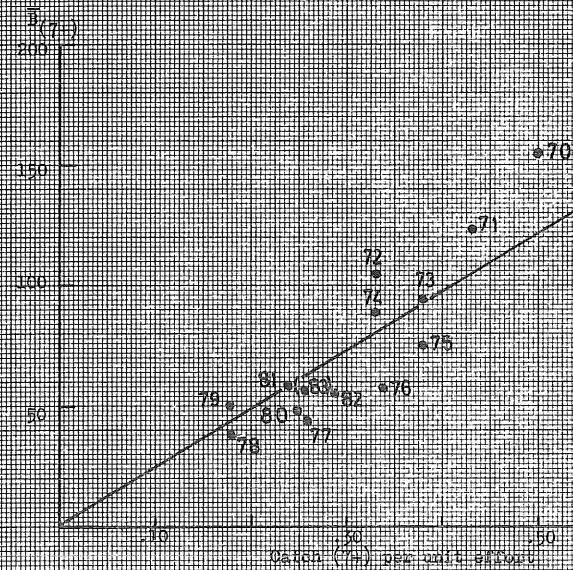

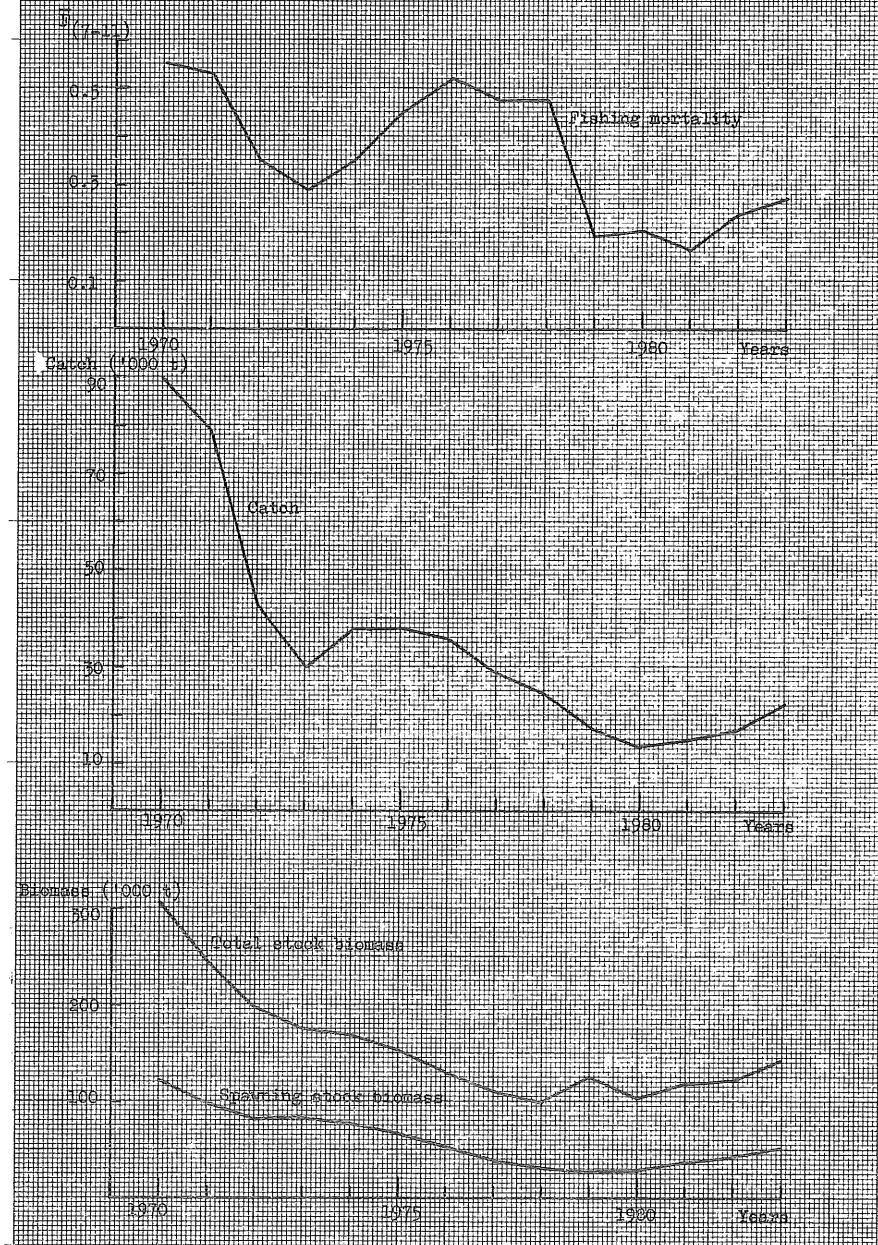

Figure 14. GREENLAND codfish in Subareas I and II.
The fishing mortality, catch and development of the stock from
1970-83.

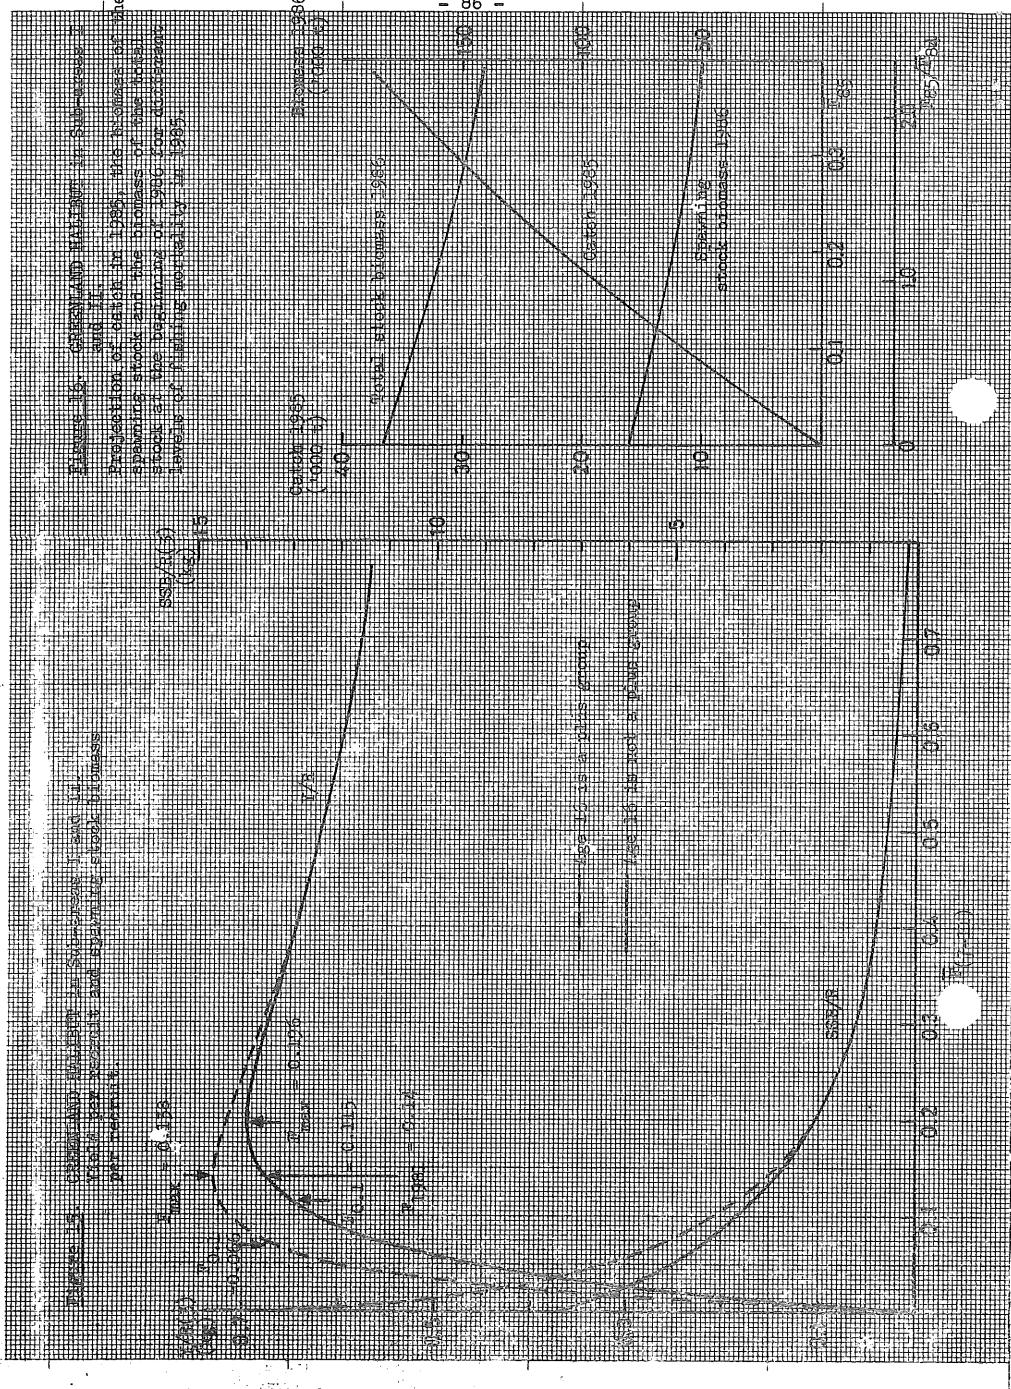

Figure 17. Groundwater nitrate in Subwatersheds V and XCV.
Relation of mean flooding nitrate (ug/l) to total rainfall (inches) (1975-82 x 10-3). The line is forced through the origin and the average values for 1975-82.

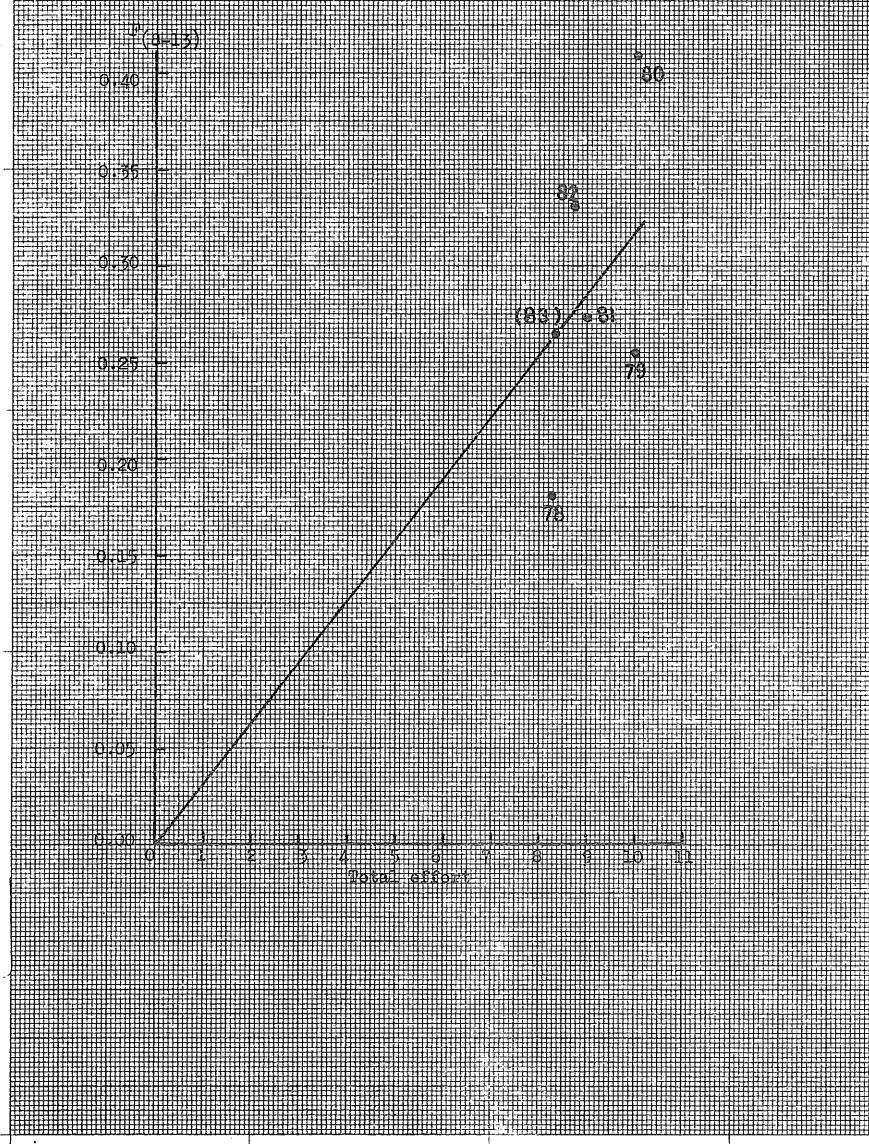

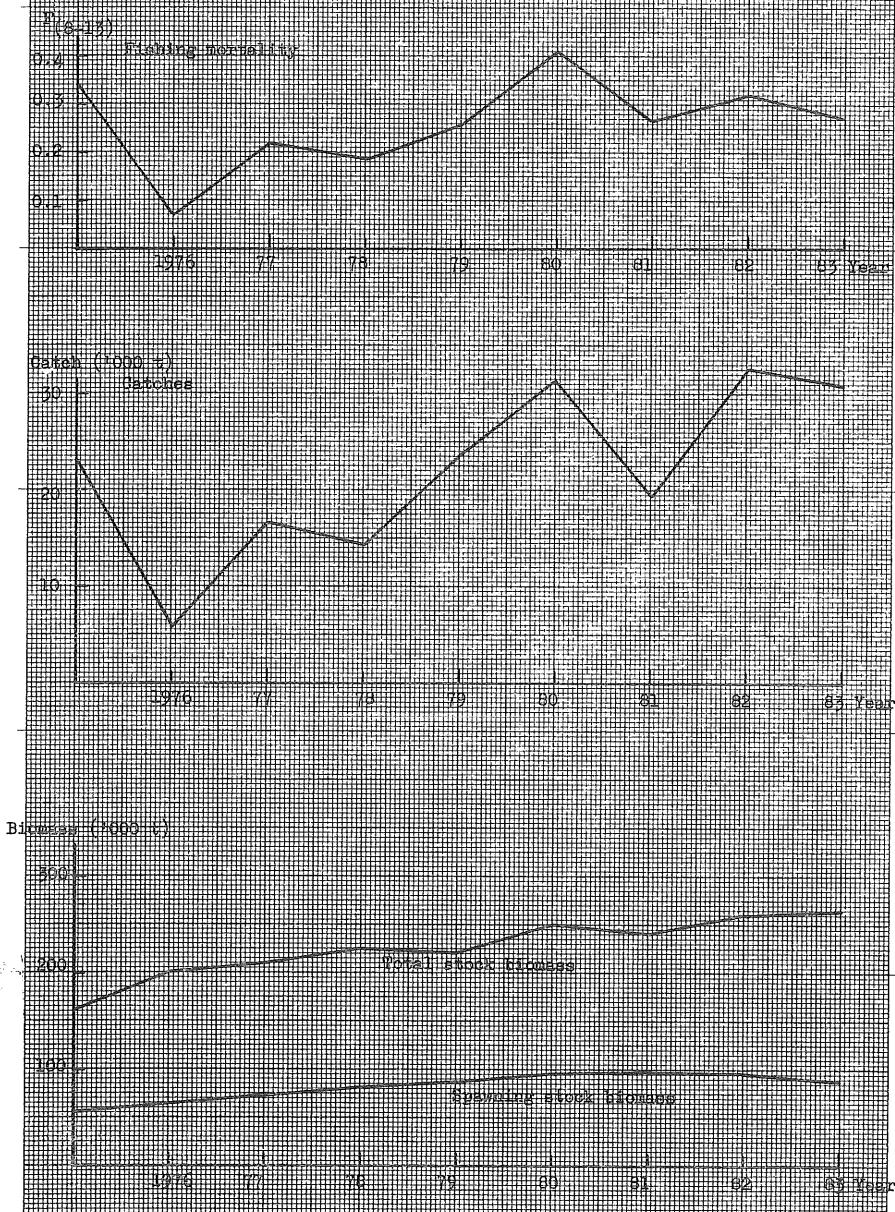

Figure 18. Cenozoic Hallibut in Sub-area V and VI
 (The fishing mortality, catch and development of the stock from 1975 to 1983)

Figures 19. GROWTH AND MATURITY in Subareas V and XIV.
Visual and spawning stock biomass per recruit.

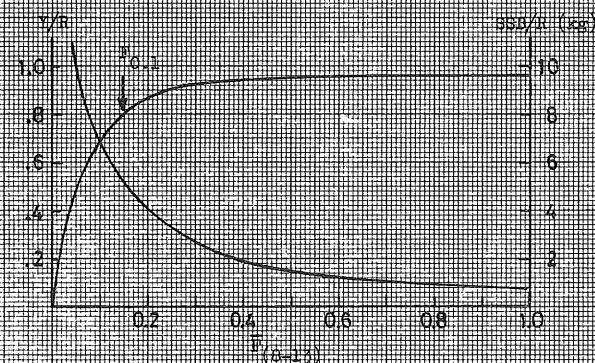

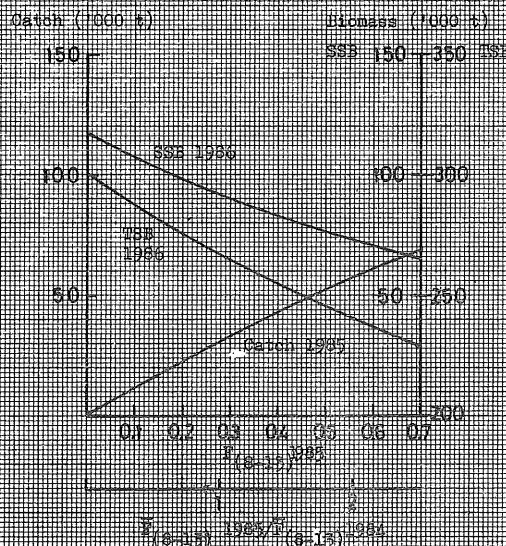

Figure 20. GROWTH AND MATURE in Subareas V and XIV.
Predictions for catch in 1983, the biomass of the
spawning stock (SSB) and the biomass of the total
stock (TSB) at the beginning of 1986.
