N.A. Nielsen	Denmark

1.2 Terms of Reference

At the Statutory Meeting in 1987, it was decided (C.Res.1987/2:3:4) that the Division IIIa Demersal Stocks Working Group will meet at ICES headquarters from 14-18 March 1988 to assess the status of and provide catch options for 1989 within safe biological limits for stocks of cod, haddock, whiting, plaice, and sole in Division IIIa.

1.3 Research Requirements

The Working Group, as last year, again points out that there is an apparent lack of basic biological knowledge of several species in the area. There are no recent studies on spawning areas and egg and larval drift of cod, haddock, and whiting in the area.

The Working Group, therefore, again recommends that research programmes be initiated by the laboratories in the countries bordering the area.

2 COD

2.1 The Fishery

Landings of cod from the Danish and Swedish fisheries were reported from the Skagerrak and the Kattegat separately. The Norwegian landings were given for the coastal areas and the open part of the Skagerrak. The Federal Republic of Germany reported some catches from the Kattegat.

Tables 2.1 and 2.2 show the landings by country for the Kattegat and the Skagerrak. The landings for 1987 are to be considered as preliminary estimates provided by Working Group members. The amounts of cod taken in the Danish small-meshed trawl fisheries are given in Table 2.3.

2.2 Cod Stock Identity

2.2.1 Skagerrak

No new information about the identity of the cod in the Skagerrak has been obtained in addition to what was said in the Working Group report in 1986 (Anon., 1986).

2.2.2 Kattegat

With no more information available than in its last report (Anon., 1987), the Working Group is still of the same opinion that the cod in the Skagerrak and Kattegat belong to two different stocks. The Working Group, therefore, again decided to assess the Kattegat and the Skagerrak cod separately.

2.3 Cod in the Kattegat

2.3.1 Catch at age

The Danish age distributions were used for all catches (Table 2.4).

Age distributions were not presented for the Danish by-catches and these were, therefore, not included in the assessment.

2.3.2 Weight at age

Mean weights at age in the catches are given in Table 2.5. The mean weights in the stock were the same as applied in earlier years (Table 2.6).

2.3.3 Catch per unit effort

The Swedish CPUE data which were reported covered only the first half of 1987, due to computer problems associated with their retrieval (Table 2.7). Danish CPUE data were based on logbooks (Table 2.8) and were not available at the meeting. The Danish and Swedish CPUE data will be worked up in April and will be available at the ACFM meeting in May.

2.3.4 Fishing mortality

The level of maximum F in 1987 was selected to fit the mean $F_{(3-6)}$ to the time series of the calculated total effort. This is based on Swedish CPUE data (Nephrops and bottom trawl combined) (Figure 2.1). The fishing pattern used and the estimates of F at the oldest ages in earlier years were obtained from a separable VPA (reference age = 6, $S = 0.8$).

F has varied at a high level around 1.1, but appeared to have decreased to 0.9 in 1987 (Figure 2.1). Fishing mortality and stock size estimated from VPA are given in Tables 2.9 and 2.10.

The relationship between CPUE and exploited biomass is shown in Figure 2.2.

2.3.5 Recruitment

Indices of recruitment from the IYFS are given in Table 2.11. The regression between indices and 1-group cod from the VPA is shown in Figure 2.3. The regression is based on the 1980-1984 year classes. An estimate of the 1985 year class can be derived from the separable VPA. This analysis suggests a fishing mortality of 0.24 on 2-group in 1987. This will, however, lead to an estimate of the 1985 year class of 48 million as 1-group. The Working Group decided to take a more conservative approach by estimating the 1985 year class from the plot in Figure 2.3. The fishing mortality on 2-group in 1987 was modified accordingly and was estimated to be 0.41. The 1986 year class at age 1 was 14.3 million fish. The 1987 year class was estimated to be 17.0 million fish compared to the long-term average (1972-1985) of 19.8 million.

2.3.6 Prediction

The input data appear in Table 2.12 and the results in Table 2.13. Stock summary graphs are shown in Figure 2.4.

2.3.7 State of the stock

Due to the incomplete data on CPUE, the assessment has to be regarded as provisional.

Spawning stock biomass appears to be very low, about 10,000 t in 1986 and 1987. The large 1985 year class will build it up to 20,000 t in 1988 if the 1987 exploitation level is maintained.

The predicted catches in 1988 and 1989 will be 13,000 and 14,000 t, respectively.

F_{max} , F_{med} , and F_{high} were estimated to be 0.26, 1.08, and 1.55, respectively.

2.4 Cod in the Skagerrak

2.4.1 Catch at age

Danish age distributions were applied to the total catch. Norwegian catches in the coastal area of the Skagerrak ("fjord cod") were not included in the assessment (Table 2.14).

2.4.2 Weight at age

Mean weights at age from the Danish samples were used and are given in Table 2.15. Mean weights for the stock (per 1 January) were obtained by smoothing the quarterly catch weights at age (Table 2.16).

2.4.3 Catch per unit effort

The Danish and Swedish data series were updated for 1987 (Tables 2.7 and 2.8). The Swedish data were, however, only given for the first half of the year.

The trends in the two data series (gears combined) are different (Table 2.17). Danish CPUE doubled in 1986 and in 1987 compared to the 1983-1985 level, whereas the Swedish data show a decrease of about 40% from 1983 to 1986, and an increase in 1987 up to the 1983 level.

2.4.4 Fishing mortality

Two sets of total effort data were calculated from the Danish and Swedish CPUE data, respectively. Test runs showed that it was not possible to choose the input F s in such a way that the trend in mean $F_{(3-6)}$ would be similar to the trend in effort based on the Danish CPUE data. The Working Group, therefore, decided to use the effort data based on Swedish CPUE to tune the VPA. The best fit was obtained by using $F = 1.25$ for age group 4 and the fishing pattern and F on the oldest ages in earlier years from a separable VPA with $S = 0.6$. The resulting array of $F_{(3-6)}$ can be seen on Figure 2.5 together with the effort array.

As seen in Figure 2.6, there is a good agreement between the Swedish CPUE and exploited biomass.

Fishing mortality and stock size estimates are given in Tables 2.18 and 2.19, respectively.

2.4.5 Recruitment

The IYFS index for the 1987 year class (Table 2.11) was almost as high as for the 1985 year class. From a regression of indices against VPA estimates, it was estimated to be 31.6 million at age 1, compared with 32.0 million for the 1985 year class. The 1986 year class was estimated to be below average (12.2 million). The 1978-1986 average is 20.7 million fish.

2.4.6 Prediction

Input data are found in Table 2.20 and the results in Table 2.21. Stock summary graphs are given in Figure 2.7.

2.4.7 State of the stock

Spawning stock biomass was at its lowest level in 1987 (10,000 t), but under status quo conditions will rise in 1988 to 19,000 t and drop in 1989 to 15,000 t.

Assuming status quo conditions, the catch in 1988 is predicted to be 20,000 t compared with an agreed TAC of 21,500 t. The expected catch in 1989 will be 24,000 t. F_{\max} was calculated to be 0.28, $F_{\text{med}} = 0.85$, and $F_{\text{high}} = 1.34$.

3 HADDOCK

3.1 The Fishery

Table 3.1 shows the landings of haddock from Division IIIa for the years 1975-1987. The landings in 1987 increased slightly to 5,261 t compared to 4,474 t in 1986. The Danish 1987 landings consist of two components, a human consumption and an industrial fishery component, which amounted to 3,572 t and 1,461 t, respectively.

3.2 Catch at Age

Catch-at-age data are available for the period 1981-1986 based on the age distribution of the Danish landings. Catch-at-age data for this period are shown in Table 3.2.

For 1987, the age distribution of the Danish human consumption component was available. Catch-at-age data for 1987 for the total international landings of human consumption fishery of 3,800 t are given in Table 3.3.

No age composition data were available for the Danish industrial fishery in 1987. This component in 1987 amounted to 28% of the total landings, and the age distribution was very different from the human consumption fishery. The age composition of the total landings of haddock in Division IIIa for 1987 could not be estimated.

3.3 Weight at Age

Weight-at-age data for 1987 were available from the Danish human consumption fishery. These data together with data for 1981-1986 are given in Table 3.4.

3.4 Recruitment

The recruitment index for the 1987 IYFS survey is shown in Table 2.11. The index of 125 of 1987 is above the average of 87.9.

No predictions of catches in 1988 and 1989 can be given. The recruitment indices for 1986 and 1987 indicate, however, catches above the 1987 catch of 5,000 t.

4 WHITING

Whiting landings in Division IIIa are given in Table 4.1. The 1987 landings of 16,682 t is very close to the 1986 landings. Biological samples were not available and an analytical assessment could not be done.

The IYFS index for 1987, shown in Table 2.11, is the highest on record, indicating a strong 1986 year class.

For the period 1980-1987, a SHOT prediction was attempted. Correlations between catches and recruitment indices were not observed.

5 PLAICE

5.1 The Fishery

5.1.1 Landings from the Kattegat

The landings from the Kattegat are shown in Table 5.1. The catch increased from 2,658 t in 1986 to 3,188 t in 1987. The landings are still on a very low level, i.e., one-fourth of the landings level in the 1970s.

The quarterly breakdown of the Danish catches from the Kattegat is shown in Table 5.4.

The increase in the Danish landings was mainly due to the increases in landings in the fourth quarter. The total landings of plaice from the combined areas (Division IIIa) are shown in Table 5.3.

5.1.2 Landings from the Skagerrak

The landings from the Skagerrak are shown in Table 5.2 for the period 1972-1987. The landings increased from 12,321 t in 1985 to 15,421 t in 1986 (the highest level since the 1970s) before decreasing in 1987 to 14,071 t. The quarterly breakdown of the Danish catches from the Skagerrak is shown in Table 5.4. The figure of the total landings is, however, as in the North Sea, very uncertain for recent years because of the lack of accurate catch statistics.

5.2 Stock Assessment for the Kattegat

5.2.1 Catch at age

Catch-at-age data were available for the Danish landings and were raised to the total landings. The catch in numbers for 1968-1987 are given in Table 5.5.

5.2.2 Weight at age

Weight-at-age data were available for each year 1968-1987 (Table 5.6).

5.2.3 Stock identity

The drastic decrease in the abundance of the Kattegat plaice was discussed in last year's Working Group report (Anon., 1987) and by Bagge and Nielsen (1988).

Danish investigations of meristic characters and growth of juvenile and adult plaice were started in 1986. Preliminary results (Bagge and Nielsen, 1987) indicate that the catch is mainly based on the Skagerrak component. Analysis of the genetic characters was also carried out, but the results are not yet analyzed in detail.

5.2.4 Recruitment

The relationship between VPA 1-group and Petersen's young fish trawl survey index is shown in Table 5.7 and Figure 5.1. Applying a regression line forced through the origin, estimates of the 1985 and 1986 year classes were obtained:

1-group in 1986 = 12 million
1-group in 1987 = 4 million

The 1985 year class is about the mean recruitment for the period 1980-1984, and the 1986 year class is well below the mean recruitment for the period 1980-1984.

5.2.5 Catch per unit effort

CPUE data were available for 1983-1987 from the Danish logbook system and from Sweden from 1980-1986.

The Danish CPUE were given as average catch in kg per fishing day for different years. Data are available for seiners, gillnets, and the two groups of trawlers. The Danish CPUE data are given on a yearly basis in Table 5.8.

The Swedish CPUE were given as average catch per hour for Nephrops trawlers and for Swedish demersal trawlers on a yearly basis. The Swedish CPUE data are given in Table 5.9.

In last year's report (Anon., 1987), the Working Group decided to combine the Danish seiner, the Swedish Nephrops, and the demersal cod trawl effort. The trends in the Swedish CPUE and the Danish seiner series were similar, and the combined data are shown in Table 5.10.

5.2.6 Fishing mortality and natural mortality

Because of the lack of Swedish CPUE effort data in 1987, only the Danish seiner and trawler CPUE series were applied. This was compared with the combined Swedish/Danish CPUE series (Figure 5.2), and a good agreement was found. The Working Group decided to select input fishing mortality which would give agreement between the exploited biomass and CPUE series. The exploited biomass was estimated using the exploitation pattern for each year. The best fit between exploited biomass and CPUE was obtained from $F = 0.48$ (Figures 5.2 and 5.3). The exploited biomass increased about 50% from 1986 to 1987 (Figure 5.2 and Table 5.11).

Natural mortality was assumed to be 0.1.

5.2.7 Results from the VPA

The results from the VPA are shown in Figure 5.4 and Tables 5.12 and 5.13.

The recent spawning stock is still at a low level, but a slight increase in the spawning stock biomass was seen in 1987.

5.2.8 Prediction

A prediction was made assuming that the exploitation pattern in 1986-1988 will remain unchanged.

The mean weights at age for the most recent years (1985-1987) were applied in 1988-1989.

The spawning stock consists of fish 3 years and older.

It was assumed that recruitment will remain at the level of the 1980s (mean for 1981-1985 was 14 million). The input data are given in Table 5.14. The catch options are shown in Table 5.15.

5.2.9 State of the stock

The assessment shows that the spawning stock biomass is still on a very low level compared with the 1970s (21,000 t in 1975-1979). This seems to be caused by the low recruitment level during the 1980s which is only half of the level of the 1970s.

With an unchanged fishery, the spawning stock biomass will be 8,000 t in 1988 and 6,000 t in 1989 and the catch in 1989 will be 2,475 t. The decrease in catch is partly caused by the very low recruitment figure in 1987.

F_{med} and F_{high} were found to be 0.39 and 0.50, respectively.

5.3 Stock Assessment for the Skagerrak

5.3.1 Catch at age

Catch-at-age data were available from the Skagerrak for 1978-1986 for the Danish landings and were applied to the total landings. The catch in numbers is given in Table 5.16.

5.3.2 Weight at age

Weight-at-age data were available since 1978 and are shown in Table 5.17.

5.3.3 Recruitment

Recruitment indices on 0-group and 1-group were not available.

5.3.4 Catch per unit effort and fishing mortality

Catch-per-unit-effort data were available from the Swedish Nephrops trawl and the Swedish cod trawl fisheries from 1980-1986 (Table 5.9). The CPUE data from Denmark were available from 1983 onwards (Table 5.8).

In earlier years, the Swedish and Danish seiner CPUE series were combined (Anon., 1987). In the absence of Swedish data, the Danish seiner data were used.

The Danish seiner CPUE series and the combined CPUE series showed an increasing trend from 1984 to 1986. The Danish seiners showed a decrease in the CPUE from 1986 to 1987 (Figure 5.5 and Table 5.10).

With a mean $F_{(3-9)} = 0.45$ in 1987, the fits between total effort and F and exploited biomass and CPUE shown in Figures 5.5 and 5.6 were obtained.

5.3.5 Results from the VPA

Results of the VPA are shown in Tables 5.18 and 5.19. The spawning biomass has increased since the early 1980s because of the good year classes in 1982 and 1983.

5.3.6 Prediction

Information on recruitment was not available.

The Working Group decided not to run any prognosis for the Skagerrak because of uncertainties in this assessment and the very uncertain estimate in the total catch figure caused by the lack of accurate data.

Catch curve analysis suggests a total mortality of around 0.9. If this value is assumed for the last year, it implies that F has increased from 1986 to 1987. This is, however, in conflict with the available indices of total effort by the Danish seiners.

6 SOLE

6.1 Landings

Landings of sole from Division IIIa are shown in Table 6.1 for the period 1952-1987. Landings in 1987 reached the maximum for the whole period of 824 t. This value is just above the previous highest recorded catch of 815 t in 1977. As expected from a fishery exploiting a sole population of many age groups, the catches show relatively slow variations. From a catch level of around 300 t in the beginning of the 1980s, the catches have gradually increased to a level of around 800 t in 1986 and 1987.

6.2 Catch at Age

Catch-at-age data for 1984-1987 were supplied by Denmark which takes around 80% of the total catch. For the fourth quarter of 1987, only a length composition by market categories was available, because the samples were not fully worked up. For this quarter, an age-length key for the fourth quarter in 1986 was applied to construct catches at age. It is believed that the final data will only differ slightly from the catch-at-age data shown in Table 6.2. The data indicate that the strong 1982 and 1983 year classes form the basis for the observed increase in the landings in recent years.

6.3 Weight at Age

Weight-at-age data were available for the Danish landings in the first three quarters of 1987. As explained in Section 6.2, however, these data were not available for the fourth quarter and Table 6.3 could, therefore, not be updated.

Using weight-at-age data from 1986, the contribution in weight by each age group was calculated (Table 6.4). The table shows that the 3- and 4-year-old sole were the most important age groups. However, sole at age 5 and above contribute, on average, more than 30% to the landings.

6.4 Recruitment

A recruitment series was available from the Danish "plaice" recruitment survey in Division IIIa (Table 6.5). Unfortunately, the survey was not conducted in 1974-1979 and 1981-1983. Since catch-at-age data were available only for 1984-1987, it is difficult to evaluate the recruitment survey data. The recruitment survey, however, shows a strong 1983 year class and is in agreement with the catch-at-age data (Table 6.2). The recruitment data also suggest a strong 1984 year class, whereas the 1985 and 1986 year classes are about average size.

6.5 Exploitation

The Working Group attempted to get a rough idea of the level of exploitation by simple catch curve analysis. The assumption of constant recruitment was not fulfilled and the results are only indicative. The analysis suggests a total mortality of $Z = 0.5$ for ages 3 and above.

6.6 Catch prediction

At its meeting in 1987, the Working Group attempted to use a SHOT estimate for prediction purposes. This possibility was further investigated this year, but it was concluded that the method was not appropriate for this fishery which exploits more than 10 age groups.

It was not possible for the Working Group to produce catch predictions for 1988-1989. It is expected that the 1983 and 1984 year classes will continue to contribute considerably to the catches, and the catch level in 1988 and 1989 is expected to remain at the catch level in 1986 and 1987.

The above considerations are based on the assumption that the level of exploitation and the exploitation pattern will remain at the present level. The agreed increase in mesh size to 90 mm from 1 January 1989 will, however, invalidate this assumption.

Using selection characteristics estimated for sole in the North Sea and the Irish Sea (Rijnsdorp et al., 1981), the Working Group made a rough calculation of the short-term losses when increasing the mesh size from 80 mm to 90 mm. The Working Group assumed that an effective 80-mm mesh size had been used by all fleets fishing sole in 1987. A relative change in selection when using 90-mm meshes was calculated using a selection factor of 3.2 and a selection range of 4 cm. If a 90-mm mesh had been applied in 1987 (instead of a 80-mm mesh), it is estimated that catches would have been about 35% lower than the recorded 824 t. A proper calculation of short- and long-term effects of a mesh change depends on a reliable analytical assessment, and this is not available for sole in Division IIIa. The short-term loss calculated above is, therefore, only indicative. The result is, however, in broad agreement with results from the North Sea (Rijnsdorp et al., 1981), and an increase in mesh size in the sole fishery from 80 to 90 mm will lead to substantial short-term losses.

Table 2.12

List of input variables for the ICES prediction program.

COD IN THE RAFFEGATT (DIV. IIIA).

The reference F is the mean F for the age group range from 3 to 6.

The number of recruits per year is as follows:

Year	Recruitment
1933	17025.0
1939	19800.0
1990	19800.0

Data are printed in the following units:

Number of fish: thousands
 Weight by age group in the catch: kilogram
 weight by age group in the stock: kilogram
 Stock biomass: tonnes
 Catch weight: tonnes

age	stock size	fishing pattern	natural mortality	maturity ogive	weight in the catch	weight in the stock
1	17025.0	.02	.20	.00	.613	.450
2	11596.0	.24	.20	.00	.751	.700

					2.0	1.78			21	32	12

The data unit of the biomass and the catch is 1000 tonnes.

The spawning stock biomass is given for 1 January.

The reference F is the mean F for the age group range from 5 to 6

Table 5.14

List of input variables for the ICES prediction program.

PLAICE - KATFESAT

The reference F is the mean F for the age group range from 3 to 9

The number of recruits per year is as follows:

Year	Recruitment
1933	14000.0
1937	14000.0
1991	14000.0

Data are printed in the following units:

Number of fish: thousands
 weight by age group in the catch: kilogram
 weight by age group in the stock: kilogram
 Stock biomass: tonnes
 Catch weight: tonnes

age	stock size	fishing pattern	natural mortality	maturity ogive	weight in the catch	weight in the stock

					2.0	.92			4	12	5

The data unit of the biomass and the catch is 1000 tonnes.

The spawning stock biomass is given for 1 January.

The reference F is the mean F for the age group range from 3 to 9
