1 INTRODUCTION

This report presents the final results for the International Young Fish Survey in February/March 1990. These data comprise as well the GOV catches of the seven standard species (herring, sprat, mackerel, cod, haddock, whiting and Norway pout), as the IKMT catches of late herring and sprat larvae. This report also gives summarized results of temperature and salinity sampling, which were, until the 1988 IYFS, presented as a separate report to the ICES Statutory Meeting.

The results from the International Young Fish Survey become available in successive steps. During the survey the numbers of 1-group fish, based on fish below a certain length, are exchanged between the participating research vessels. Immediately after the survey the length compositions of the seven standard species are sent to ICES (in IYFS exchange format), to be used by the different assessment working groups, together with all age-length keys which are available by then. Final data, including length compositions for all species and age-length data, should be submitted to ICES before 15 April. These data are then checked and stored in the ICES IYFS data base, in order to be able to run the final analysis in time for the May meeting of ACFM. This report is based on the analysis done in May 1990.

2 SURVEY METHODS AND PARTICIPATION

For all matters on survey methodology, the reader is referred to the IYFS Manual (ICES, Doc. C.M. 1986/H:2). Details on the participation in the 1990 survey are given below. As in 1988 and 1989 the weather during the 1990 survey was rather bad, which restricted the total number of stations which could be fished. Especially the coverage of the IKMT stations was rather poor.

The contribution to the 1990 IYFS by the Netherlands was limited due to the replacement of "Tridens" in the course of February. The 'old' "Tridens" took part in the International Young Fish Surveys since 1969.

Country	Vessel	Period	Number of hauls	
			GOV	IKMT
Denmark	"Dana"	30-1/15-2	24	35
France	"Thalassa"	02-2/23-2	58	-

UK England	"Cirolana"	27-1/18-2	57	60
UK Scotland	"Scotia"	01-2/20-2	52	30

3 DATA AVAILABLE

In Table 3.1 is shown which data were available in the ICES IYFS data base at 1 August 1990.

At the time of the final analysis of the 1990 survey, all final data were available in the data base except for Swedish age/length keys for cod in Skagerrak/Kattegat. The numbers at age for cod in that area were added to the figures later.

4 STANDARD OUTPUT FROM THE ICES IVFS DATA BASE

For details on the standard analysis of the data the reader is referred to a description by Pedersen (1989). At request, copies of this paper are available at the ICES Secretariat.

5 RESULTS GOV-TRAWL FOR 1990

5.1 North Sea

Preliminary indices based on certain size classes and indices used by the Assessment Working Groups are compared with the final indices and shown in Table 5.1. In the case of the pelagic species herring and sprat the indices are very close. Indices of 1- and 2- group fish of the six standard species from year class 1969 and onwards are given in Table 5.2 The mean age composition of the standard species in the catches within the relevant standard area are shown in Table 5.3.

Figure 5.1 shows the number of hauls used for the analysis of the herring data and the number of hauls used for the other standard species is shown in Figure 5.2. Per species there is a set of figures which gives the distribution of the 1-, 2-, and 3+ group and the mean length of 1-group fish per rectangle. The standard area used to calculate the index of year class strength is indicated in the figures.

HERRING

The indices for age groups 1 and 2 are given in Table 5.2 and the mean number per one hour trawling of 1-, 2- and 3+ group is shown in Figures 5.3 to 5.5. The mean length of the 1-group per rectangle is presented in Figure 5.6.

The 1987 year class was estimated in 1989 to be comparable to the 1983 and 1984 year classes as 1-ringer. The present estimate of the 1987 year class as 2-ringer is 443 which is the lowest estimate since the 1981 year class and about half of the 1983-1984 year classes as 2-ringer. A reduced abundance of North Sea herring is also indicated in Skagerrak-Kattegat (Table 5.4). The distribution of the 2-ringed herring was similar to the distribution in previous years with highest abundance in the northern and western parts of the North Sea (Figure 5.4).

The preliminary index of the 1988 year class is 2224 and the final index 2146. The index is about 60% of the 1987 year class and reflects a trend of reduced recruitment to the North Sea stock. The 1988 year class was distributed in the traditional nursery areas in the southeastern part of the North Sea (Figure 5.3). A reduced abundance of 1-ringed herring is also corroborated by a lower number of North Sea autumn spawners in Division IIIa (Table 5.4). Age group 3+ was found in the northern and northwestern parts of the North Sea (Figure 5.5).

SPRAT

Sprat indices of 1- and 2-group are given in Table 5.2. The distribution of the same age groups and the 3+ group as well as the mean length of 1-group per rectangle are shown in Figures 5.7-5.10.

The 1988 year class was estimated in the 1989 IYFS as being the highest on record since 1972. It was noted that the high index was totally dominated by an extremely large mean catch in only one rectangle, although this value was based on 5 hauls. There was no obvious reason to reject the high catches but the index was assumed to overestimate the strength of the 1988 year class. The same year class is now estimated as 2-group in 1989 to be close to the average of the preceding seven year classes and the 2-group index does not support the previous estimate of a very strong 1988 year class.

The index of the 1989 year class is 177 which is far below the historical average and indicates a very poor recruitment to the stock.

MACKEREL

Indices for mackerel are given in Table 5.2 and the distribution of 1-, 2- and 3+ group is shown in Figures 5.11-5.13. The mean length of the 1-group per rectangle is presented in Figure 5.14.

An unusual high concentration of both juvenile and adult mackerel was found in the western North Sea off the English east coast (Figures 5.11-5.13). The index for 1-group mackerel, 35, is the highest on record since 1975.

COD

Indices are given in Table 5.2, the distribution of 1-, 2- and 3+ group and the mean length of 1-group fish is given in Figures 5.15-5.18.

The abundance of the 1989 year class at 1-year-old is far below both the abundance of the 1988 year class and the historical average and at approximately the same level as the 1987 year class which was the second poorest year class in the historical series.

The 2-group index is at the level of the historical average.

The highest catches of 1-group fish were made in the central North Sea and in one rectangle (39E8) off the coast of northern England. In the German Bight almost no 1-group cod was caught. Two-year-old cod was mainly concentrated in the northwestern North Sea.

HADDOCK

Indices are given in Table 5.2, the distribution of 1-, 2- and 3+ group and the mean length of 1-group fish is given in Figures 5.19-5.22.

The index of 1-group haddock is at the same level as the index of the 1988 year class and far below the historical average, indicating that the 1989 year class is the third consecutive very poor year class.

The index of 2-year-old fish confirms the low abundance of the 1988 year class at 1-year-old.

WHITING

Indices are given in Table 5.2, the distribution of 1-, 2- and 3+ group and the mean length of 1-group fish is given in Figures 5.23-5.26.

Although the index of abundance of the 1989 year class at 1-year old is far below the index of the 1988 year class (the highest one in the series), it remains at the historical average level and at a higher level than the 1987 year class. The number of 2-group fish is the higher of the series (2.5 times the average), confirming that the 1988 year class is the strongest one since 1970.

The largest catches of 1-year-old fish were widely distributed over the North Sea. The 2-year-old fish were concentrated in the western half of the North Sea.

NORWAY POUT

Indices are given in Table 5.2, the distribution of 1-, 2- and 3+ group and the mean length of 1-group fish is given in Figures 5.27-5.30.

Catches of 1-group Norway pout were below the historical average and about two third of those of 1989. The 2-group index confirms that the 1988 year class is approximately at the average level.

Concentrations of 1-group Norway pout were found more northerly than last year.

5.2 Skagerrak-Kattegat (Division IIIa)

The number of hauls per rectangle for herring and gadoids is shown in Figure 5.1 and 5.2.

The final indices for 1- and 2-group herring and 1- and 2+ group of sprat are given in Table 5.4. The herring indices are calculated as the mean catches in four depth strata, covering the depth range of 10 - 150 m, and weighted by the surface area of each stratum. Details of the analysis and separation of spring- and autumn spawners are given in the 1989 report (Anon., 1989).

Age/length keys for cod are now available from the 1981 IYFS and onwards. The stocks of cod in Skagerrak and Kattegat are assessed separately and indices are given for each area. Final and preliminary indices for whiting and haddock are given in Table 5.5.

The distribution of herring, sprat, and cod is included in the figures in Section 5.1.

HERRING

The indices are given in Table 5.4 and the distribution is shown in Figures 5.3-5.5. The mean length of 1-group is shown in Figure 5.6.

The final index for 1-group herring was 3544 which is the lowest value since 1983. Meristic characters show that the 1-group is dominated by North Sea autumn spawners. The 1-group herring was mainly distributed in shallow waters in the southern part of Kattegat and around the Skaw.

The total index of 2-group herring, 3876, is above the historical average. Most of the 2-group herring could be assigned to spring spawners with an index of 3192 compared to the index for autumn spawners of 684.

SPRAT

The index of 1- and 2+ group sprat is given in Table 5.4 and the distribution of 1-, 2- and 3+ group is shown in Figures 5.7-5.9. The mean length of 1-group sprat per rectangle is presented in Figure 5.10.

The index of the 1989 year class is 503 which is the second lowest since 1974 and about the same level as the very poor 1988 year class. The index of the 2+ group, 471, is the lowest on record.

COD

Indices are given in Table 5.5, the distribution of 1-, 2- and 3+ group is shown in Figures 5.15-5.17.

The 1988 year class is estimated as 2-group in 1990 to be the weakest since year class 1979 in both Skagerrak and Kattegat. This year class was estimated as 1-group in the 1989 IYFS to be above average in Skagerrak and very weak in Kattegat.

The 1989 year class is estimated to be close to the average in Skagerrak and strong in Kattegat.

HADDOCK

The index of haddock <20 cm is the second lowest on record and indicates a very weak year class.

WHITING

The preliminary index of 2255 is the second highest since year class 1974 and indicates a strong 1989 year class.

6 RESULTS OF IKMT SAMPLING IN 1990

During the IYFS herring and sprat larvae are sampled using an Isaacs-Kidd Midwater Trawl (IKMT). For details of methodology see the IYFS Manual (ICES, Doc. C.M.1986/H:2).

Series of oblique hauls are made at night and the abundance of larvae in each haul is expressed by an index value that, to some extent, corrects for differences in haul profiles:

$$\frac{\text{number caught} \times \text{water depth (m)}}{\text{haul duration (min)}}$$

A mean of index values and of larval mean lengths is calculated for each standard rectangle. The values for the 1990 sampling are shown in Figure 6.1. Finally mean abundance is calculated for larger areas (these areas are given in ICES C.M. 1988/ Assess:17, Figure 2.3.2) and raised by an area factor. An overall index of larval abundance is calculated by adding abundances in the individual areas (Table 6.1).

HERRING

In February 1990 the unfavourable weather conditions limited the IKMT sampling, and part of the standard rectangles were not sampled. A total of 213 hauls was made. Most catches contained only a few herring larvae. Significant densities were only observed in a restricted area in the central/northern part of the North Sea and in the Skagerrak (Figure 6.1). The 'Northwest' and 'Northeast' regions were not sampled during the IYFS, and sampling performed during a cruise in late January by DAFS Aberdeen, is used in estimating indices for these two regions.

The indices and the overall index are given in Table 6.1. The overall IKMT index is very low, and a dramatic reduction since the 1986 year class is observed. This year's index is as low as the lowest figures recorded (the 1976 and 1977 year classes).

The preliminary IYFS recruitment index for 1-ringed herring, year class 1988, was compared with last year's prediction based on the IKMT index (Figure 6.3).

The IKMT index predicted the year class to relatively smaller than the IYFS index, however, they both foresee the strength to be lower than has been attained since year class 1982. The comparison between IKMT index and IYFS index might be somewhat biased. The IYFS index (as well as the North Sea VPA estimate) do not include juvenile herring in the Skagerrak (IIIA), while the IKMT index includes catches of larvae made here, and also the larvae found off the Danish coast which probably will drift into these areas. These problems are discussed in ICES C.M. 1990/ Assess:14, pp. 10-11.

The mean length of herring is shown in Figure 6.2. This year the herring larvae were relatively small compared to previous years. Samples with larvae of a mean size above 35 mm were seldom whereas normally significant numbers are seen in the southern part of the North Sea.

SPRAT

The number of sprat larvae caught was very low, and does not allow an interpretation of their distribution.

7 HYDROGRAPHIC DATA

Hydrographic stations were submitted by all participating countries but France. A total of 332 stations were worked, and at 108 of these, nutrients were also collected (by England, Scotland, and Denmark).

The temperature distribution (Figure 7.1), once again reflected the very mild winter, the third in a row. Positive temperature anomalies ranged from 1°C in the northwest to 3.5°C off the German/Danish coast. The salinity distribution (Figure 7.2) showed no marked anomalies except off the German/Dutch coasts where excesses greater than 0.3 occurred. In spite of these higher than usual salinity values, nutrient levels, especially silicate, were exceptionally high across the North Sea between 54° ad 55° N. In this area values have normally been in the range of 3-5µM, but this year's data showed values in excess of 8 over a wide area, with no clear association with the salinity distribution. This points to the possibility of analytical errors but the vigorous resuspension processes that must have occurred at this time, because of extremely severe weather, may have contributed to these anomalous nutrient levels, especially silicate. Figures of nutrient distributions are not included here, but these as well as temperature and salinity anomaly charts are available from the Secretariat.
