## Report of the Northment Arctic Fisheries Working Group

1. Participation

| Mre D.J. Gaxrod | United Kingdom |
| :--- | :--- |
| Mr A. HyIen (Chairman) | Nonway |
| $M r$ BoW. Jones | United Kingdom |
| $M r$ S.D. Melnilsor | USSR |
| Dr V.D. Ponomarenko | USSR |

Mr D. de G. Grifith, ICES Statistician, also took paxt in the Meeting.
2. Terms of Reference

At the 1973 Statutory Meeting of ICBS the Sollowing Resolution (CoRes.1973) 2:20) was adopted:
"It was decided that:
the Northemast Arctic Fisheries Working Group meets at Charlottenlund from 18 to 22 March 1974 to:
a) continue assessments of the Arcto-Norwegian cod and haddock stocks;
b) assess the effects on individual countries catches of the proposed increase in mesh size to 145 momanila:
c) examine the proposal for such an increase in relation to other proposed regulatoxy measures, e.g. quotas;
d) examine the effect of the proposal concerning mesh size on the size of the spawning stock and whether it would obtain the optimal level of recmuitment."
3. The Status of the Fisheries
3.1. Cod (Tables 1 -4).

At the 1973 Meeting of the Working Group provisional cateh and effort atatistics were not available for all countries and thexefore the data for 1972 given in this Report differ from the estinates which were given in the last Report.

In 1973 there was a big improvement in catches from Submarea I and Division ITb resulting from the recxuitment of the 1969 and the vexy rich 1970 year classes. Catches in Division ITa declined as expected as a result of the reduced size of the mature part of the stock. The abundant 1963 and 1964 year classes which gave improved catches on the Nowway coast in 1971 and 1972 are now past making theix maximum contribution to the catches. The spawning fishery is now expected to continue to decline until the 2969 and 1970 year classes reach maturity.

The estimates of total fishing effort on cod in English and USSR unjts (Table 3) give conflicting indications of the tread in the amount of fishing. part of this discrepancy is likely to be due to an underestimate of catch-per-unito effort of English trawlers because of rejection at sea of young fish. The general impression, however, is that there was an increase in the amount of fishing in Sub-area I and Division IIb while there was very little change in Division IIa.
3.2. Haddock (Tables 5-7).

Whe estimates for haddock landings in 1972 given in the 1973 Report were much more seriously in exror than were those for cod. 1972 catches in all areas showed big increases compared with 197l following the recruitment of the abundant 1969 year class. Catches increased again in 1973 in Subarea I and Division IIb, but the decline in Division IIa resulted from the redued size of the mature part of the stock as year classes after those of 1963 and 1.964 axe of lower abundance.

Fishing effort on haddock probably reduced slightly in 1973 after an increase in 2972.
4. Rishing Mortality (Tables 8 and 9).

Provisional age composition data were available for catches in 1973 taken by Fogland, Nowway, Federal Republic of Gexnany and the USSR. These data prom vided the basis of estimates of the age composition of the total 1973 catches of cod and haddock which were used to update the Virtual Population Analysis (VPA). Revised data for the 1972 catches were also available.

For cod, estimates of fishing mortality in 1973, used to initiate the VPA, were similar to the values used at the last Meeting of the Gxoup. These estimates were derived from information on probable trends in fishing effort with additional guidance from an analysis of the data by a new method (unpublished) being developed by Mr J. Pope of the Fisheries Laboratory, Lowestoft, Fagland. For haddock, values slightly lower than last year were used since it is believed that the fishing effort on haddock in 1973 was slightly lowex than in 1972. Results of the VPA are given in Tables 8 and 9.
5. Recxuitment (Tables 10 and 11).

For cod, the year classes 1965-1968 have all been very weak (Table 10). The fisheries in Submarea I and Division ITb are now beginning to benefit from the recrustment of more abundant year classes. The 1969 year class now seems to be not so abundant as had appeared from the rather poor provisional data available at the 1973 Meeting. The most recent estimate indicates that it is slightly above average size. The 1970 year class which recruited to the fishery in 1973 is fulfilling earlier expectations and it is well above average abundance, although it is still too early to bave an accurate estimate of its size. Of the subsequent year classes of cod, the indications from 0-group and young fish surveys, are that those of 1971 and 1972 are of about average size and that of 1973 is very abundant.

For haddock (Table 11), the vexy abundant 1969 yeax class has been joined in the fishery by the 1970 year class which is also well above average abundance.
 average size and that of 1973 below average.
6. Effective Mesh Size in Use

Botton trawling experiments with double cod ends were made in Apxil and June 1973 by Norway off the tast rinmark coast. The mesh sizes in both cod ends were 130 mm . The catches were sorted by fishermen into those fish acceptable for landing and those to be discarded, according to current comercial practice. In this maner discarding rates, by number, of between $23-28 \%$ were found. All fish less than 35 cm and most of the fish in the length group $35-39 \mathrm{~cm}$ were discaxded. No fish greater than 49 cm were discarded.

Some of the countries fishing in the Northmest Arctic are known to discard small fish at sea. Presuming this to be reflected in the length composition of landings which show a higher mean length, the discard factors deduced from the experiments were applied to the landings of countries $B$ and $C$ in Pigure 1 .

The adjusted length frequency of these landings then appear to be very similar to the unadjusted landings of country Ao The correction implies discarding of $4 \%$ and $37 \%$ by numbers by countries $B$ and $C$ in 1973.

The similarity between length compositions of comercial catches, adjusted for discarding, and the length composition of experimental hauls using double cod ends of 130 mm might be taken to indicate that the enforcement of Commission regulations is inadequate.

No doubt this may occur from time to time, but a similar effect might be achieved by the concentration of the fishery in areas where the new year class is rost abundant, so that the selection of cod by trawl cod ends of the Commission size is influenced by the abundance and behavjour of the fish. Whatever its cause, it is apparent that in 1973 at least the effective mesh size of cod ends was lower than 130 mm , and 115 ma has been adopted as a working value for estimating the immediate loss that may be caused by changing to a new mesh size.

## 7. Assessments

The effects of changes in mesh regulations were calculated in two ways. The Gulland method using length composition data was used to estimate immediate losses. Another method based on age composition of the stock and tishing mortality data was used to estimate the longoterm change and also the catches to be expected in each year 1975 - 1977 if a mesh size of 130 mm or 145 mm were to be introduced in 1975.

### 7.1. Estimates of Tmmediate Losses (Gulland Method).

If the Gulland method is to be successfully applied the length composition of the population should be relatively stable. At present in the North-Rast Arctic the size compositions of the stock fluctuates from year to year with vaxiations in year class strength. The result of a mesh change in this situation will depend critically on the relative abondance of the recruiting year classes. The calculations were based on the average length compositions of the catches in 1968 and 1969 for cod and 1969 and 1970 for haddock when the relative strengths of the recruiting year classes were similar to those expected in 1975 and 1976. For cod, some allowence has been made for rejection. It has been assumed that there was no rejection by USSR vessels, but the rejection rate for trawlexs of all other countries was estimated on the basis of the relative abundance of the smallest age groups in their landings compared with USSR catches. No allowance was made for rejection of
bedock. The immediate loss was calculated for increases to 130 mm and 145 mm from 115 mm which is the pxesent estimated effective mesh size.

Fox cod, an increase to 130 mm would be expected to result in a $6 \%$ immediate loss for USSR catches with very little change for other countries. An increase to 145 mm would result in immediate losses of $16 \%$ and $7 \%$ for USSR and U. K., and $6 \%$ for Norwegian trawlexs. For haddock, the magnitude of the immediate losses would be greater, being $20 \%$, $3 \%$ rox USSR and U.K. and $3 \%$ for Noxwegian tramlers, for a change to 130 mm . The cormesponding immediate losees for a change to 145 mm would be $36 \%, 12 \%$ and $11 \%$.

### 7.1.2. Estimates Based on the Age Composition Method.

The Tables belov sumarise the immediate and longoterm effects of possibla adjustments to the mesh regulations, depending upon the efrective mesh size at present in use (see Section 6).

## Immediate Effects (\%)

| Species | Method | $\begin{gathered} 1973 \\ \text { mefective } \\ \text { Mesh (man) } \end{gathered}$ | New <br> Mesh <br> (mm) | USSR | Nowway |  | O. K . | Gexmany$\left(\mathrm{F}_{\mathrm{o}} \mathrm{R}_{\circ}\right)$ | Others | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  | Trawl | Total |  |  |  |  |
| COD | VRA <br> GuIland | 115 | 130 | $-6$ | - 1 | -2 | $\begin{array}{r} -7 \\ -2 \end{array}$ | -1 | -7 -1 | -8 |
|  | vPa. Gulland | 115 | 145 | $\begin{aligned} & -17 \\ & -16 \end{aligned}$ | $1-6$ | - 8 | $-14$ | -1 | $\begin{array}{r} -13 \\ -2 \end{array}$ | -13 |
|  |  | 130 | 145 | -7 |  | -6 | - |  | - 6 | - 6 |
| HADDOCK | $\begin{aligned} & \text { VPA } \\ & \text { culland } \end{aligned}$ | 115 | 130 | -16 -20 | -3 | $+5$ | $\begin{array}{r} -4 \\ -3 \\ -3 \end{array}$ | - 1 | $\begin{array}{r} -27 \\ -2 \end{array}$ | -9 |
|  | vea <br> Gulland | 115 | 145 | $\left\lvert\, \begin{aligned} & -33 \\ & -36 \end{aligned}\right.$ | $\mid-11$ | -7 | $\begin{array}{r} -20 \\ -12 \end{array}$ | - 7 | $\begin{array}{r} -45 \\ -8 \end{array}$ | -25 |
|  |  | 130 | 145 | -20 |  | -11 | - 7 |  | -25 | -17 |

If a new mesh regulation were introduced in 1975, the traw fishexies which would show the greatest immediate losses would be those of the Barents Sea and the Bear Istand - Spitsbergen area, and there would be a greater loss for haddock than for cod.

Longmexm fefects (\%)

|  | 1.30 | 145 | $\cdots 4$ | +21 | +22 | +20 | $+9$ |

The long-texm change in tbe ood fishery would be small, even allowiag fox some uncertainty in the level of natural moxtaitity that should apply. However, with a total long-texm gain of perbaps $5 \%$ there fould be some rediatribation of catoh in favoar of fisheries based on oldex cod. Thexe wowld be a somexhat greater long-term gain in the total cotch of baddock (perheps up to 20\%) but with a greater redistribution of catra betwean axeas and countries.

### 7.2. Dstimates of Futuxe Catches and the pesect of Changes in Mesh Regulations Besed on Age Composition.

### 7.2.1. Txends in Catches.

Prospective catches of cod and haddock have been entimated for bwo levels of fishing and three megh sizes as gummaxised in Table 12. Prospective catohes at the present mesh size are abstracted below ior two levels of fishing: (i) if the 1973 level is malncained and (ij) if it in reduced by $25 \%$ to approach the level of fishing mortality giving the Marimum Suatainable Field per recruit.

|  | Cateh (000 tons) |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Level of Fishing (IP) as in 1973 |  |  | $F=3 / 4$ of the Level in 1973 |  |  |
|  | I + IIb | IIa | Total | I + IIb | IIa | Total |
| COD | 577 | 109 | 686 |  |  |  |
|  | 736 | 77 | 81.3 | 585 | 62 | 64.7 |
|  | 804 | 105 | 909 | 684 | 97 | 781 |
|  | 828 | 171 | 999 | 726 | 178 | 905 |
| EADDOCK | 207 | 17 | 224 |  |  |  |
|  | 182 | 37 | 220 | 1.44 | 30 | 1.74 |
|  | 162 | 22 | 184 | 141 | 20 | 161 |

If cod catches in 1974 do not exceed the tripartite Agreement level of 550000 tons then prospective catches for 1975 - 1977 will be slightly higher. Haddock catches bave also been estimated assuming the 1973 level of fishing is maintained but these may be inaluenced by interaction between the two figheries. For example, if cod and haddock are alvays caught together, then the haddock catch may be limited by the possibilitioc for catching cod.

The estimated catches given above can be compared with separate estimates of 1 110, 1165 and 1240 thougand tons for the years 1974,1975 and 1976 respectively prepared by USSR scientists using a technique based upon the historic pexformance of the fishexy relative to changes in year olass strength (see Appendix). However, the Group noted that in 1968 the cetch of this magritude came from a atock which contained two outstanding year classes (1963 and 1964) as 4 and 5 yearmold fish, and additional stock of older age groups whereas now, in 1974 , the stock contains only one good. fear clasg (1970) as 4 year olds and the stock of older age groupg is particulaxly meak. The Groap therefore coxsidexed the ussh entrinter fore 1974 and 2975 to be optimistic.
7.3. The Effect of Regulations Tpon the Siae of the Spawaing stociso

The Group has previously expressad concern at the declining sime of the spaming stock of cod, and eaxliex reports bave stressed the need to ensure that an adequate quantity of cod from the 1970 year class survive to augment the sparning stock from 1978 onwards. The effecte of regum lation of the fishing mortality and/or mesh size on the size of the spawning stock are summaxised below by comparison of the expected size of the spawning stock at the beginaing of 1978 (before the spaming season) for difierent mesh adjustments.

|  |  | $\begin{aligned} & \text { Level of fishing } 1975-1977 \\ & \text { as in } 1973 \end{aligned}$ |  | $\begin{aligned} & \text { Level of Fishing } 1975-1977 \\ &=0.75 \times 1973 \text { Level } \end{aligned}$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| nefective <br> Mesh Size <br> In Porce (mm) | $\int_{(\mathrm{mm})}$ | Index of Cod Spaming Stock in 1978 | No. of Cod Aged $8+$ in 1978 (Millions) | Index of Cod Spaming Stock in 1978 | $\begin{gathered} \text { No. of Cod Agw } \\ 8+i n 1978 \\ \text { (Minlions) } \end{gathered}$ |
| 315 | Present Drecective | 734 | 99 | 1020 | 142 |
| 115 | 130 | 759 | 101 | 1052 | 145 |
| 115 | 145 | 806 | 106 | 1063 | 150 |

Clearly a reduction in fishing mortality will achieve more rapid recovecy of the gpawning stock than mesh regulations the most rapid recovery would be achieved by a combination of measures. It is not certain rhat the best level of spawning stock should be, but the Group noted that in $1970-1972$ the number of mature cod of 8 years and older averaged 136 millon. This might perheps be a first objective, knowing that the recovery can be expected to continue in the years following 1978 and may later come to approach moxe closely the level of 212 million, averaged in the years $195 n$ m 1959.

The cod catches in thousands of tons for the period 1974-1977, associated with the two levels of fishing, are:

|  | Level of Fishing $(F)$ as in 1973 | $F=3 / 4$ of the Level in 1973 |
| :---: | :---: | :---: |
| 1974 | 686 | 686 |
| 1975 | 813 | 647 |
| 1976 | 909 | 781 |
| 1977 | 999 | 905 |

Together, these serve to show that a recovery in the spawning stock at least to the $1970-1972$ level could be achieved by careful regulation of the catches in the coming years. In effect, management can take advantage of the improving stock to reduce fishing moxtality without reducing actual catches. It is, however, easential that a regulation be maintained to prevent unrestricted increase in fishing on the whole stock within the period $1975-1977$, and to prevent too high a proportion of the allowable catch being taken from the mature stock.

Figure 2. Fexcentage Length Compositions of Cod Landed in 1973 by Three Countries. Adjusted Length Corapositions Allowing for mstimated Rejection Rates are also shown fox Countwies B \& G

by
V.P. Ponomarento

PTNRO, Kolskaya 6a, Muxmankk, USSR.
(A Voxlsing Paper presented to the 1974 Meetiac of the Morthe Dast Aretic Beaheries Vorking Gxonp)

At recent levels of intensity, the sighexy is besed on 3 - 7 year-old sish in the iattoning areas and on $7-10$ gear olde on the spaming grounds.

In $1974-1976$, fish of the gegen mentioned above vill belong to those geax classes given below.

| Year of Tighery | Age, Year Class |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |  |
|  | 1971 | 1970 | 1969 | 1968 | 1967 | 1966 | 1965 | 1964 |  |
| 1975 | 1972 | 1971 | 1970 | 1969 | 1968 | 1967 | 1966 | 1965 |  |
| 1976 | 1973 | 1972 | 1971 | 1970 | 1969 | 1968 | 1967 | 1966 |  |

The estimates of abundance of these year elasger of cod axe shown in Appendix Table I and for haddock in Appendix Teble IT.

The fish at the age of 4,5 mad 6 years doninated in cod catobes in the fattenuag areas. The cod of the extrememy abundant 1970 year class and tro faixly abundant year clesses vill be at the mentioned ages in 1974/5/6 (the 1968 and 1969 year classes in 1974 , the 1971 and 2969 ones in 1975 and the 1971 and 2972 year olessea in 1976).

Thua, the state of the cod stocks in the iotbeaing axean in 1974, 1975 and 1976. will be at the level of maximum years. The mature cod stoolss in these yeasg will be minimum sor the recont $10 \Rightarrow 15$ Jears observed.

Haddock constitute on the average about $20 \%$ of the long-term mean catch of cod. The $i$ sh of the abundant 2969 and 2970 year classes at the $3 g e$ of 4 and 5 Jeare will form the basis of haddock catches in 1974 ot ages 5 and 6 in 1975 , and at 6 and 7 years old in 1976 .

The 3, 4 and 5 year olds axe the most traportant for the haddock fishexy. The commercial beddock stocks, excluding 1974 , will be below the longotexu mean level.

Taking into account the age composition of the catches, pxMo composed methods for comercial forecasts of fish resources for trawl fishery of demersal fishes in the Barents Sea. The fishexy forecasts compiled by these methods are of satisfactoxy xeliability。

The prediction equations used for forecasting the total catches of cod and haddock by all countries in 1974, 1975 and 1976 axe as rollows:

$$
\begin{equation*}
y=4.58 x+388 \quad x=0.70 \tag{1}
\end{equation*}
$$

$x=$ index of cod stock abundance for the whole area, $1974-1989$, $(1975=105,1976=113)$ :
$y=$ cod yield (thousands of tons) in the fattening areas by all countries.

$$
\begin{equation*}
y=5.98 x+214 \tag{2}
\end{equation*}
$$

$x=$ index of cod stock abundance in Subarea $I$, $(1974=92,1975=97,1976=101)$;
$y=\operatorname{cod} y i e l d$ (thousands of tons) in Sub-area I by all countries.

$$
\begin{equation*}
y=1.34 x+14, \quad x=0.95 \tag{3}
\end{equation*}
$$

$x=$ cod yield (thousands of tons) in subwarea $I$ by all countries, $(1974=764,1975=794,1976=818)$;
$y=$ cod yield (thousands of tons) in the fattening axeas by all countries.

$$
\begin{equation*}
y=0.997 x+289 \quad x=0.95 \tag{4}
\end{equation*}
$$

$x=$ cod yield (thousands of tons) in the fattening axeas by all countries, $(1974=920,1975=975,1976=1050) ;$
$y=\operatorname{cod} y i e l d$ (thousands of tons) over the whole fishing axea by all countries.

$$
\begin{equation*}
y=0.0029 x+189 \quad x=0.86 \tag{5}
\end{equation*}
$$

$x=\operatorname{cod} y i e l d$ (thousands of toms) in the fattening areas by all countries,
$(1974=920,1975=975,1976=1050)$ :
$y=\operatorname{cod} y i e l d$ (thousands of tons) in Division IIa by all countries.

$$
y=3.38 x+24 \quad x=0.64
$$

$x=$ index of haddock stock abundance,
(1974=31, $1975=7,1976=2)_{;}$
$y=$ haddock yield (thousands of tons) by UssR trawlers.

$$
\begin{equation*}
y=0.889 x+91 \quad x=0.89 \tag{7}
\end{equation*}
$$

$x=$ haddock yield (thousands of tons) by USSR trawlers, $(1974=130,1975=50,1976=30) ;$
$y=h a d o c k$ yield (thousands of tons) over the whole fishing area by vessels of all countries.

Alrost all the equations give a satisfactory coincidence of calculated catches and actual ones. The poorest agreement is obsexved in the calculation of the cod catches in Division IIa. This may be explained by the fact that different cod are fished over this area ("capelin" cod, prempawning and spaming), and also various fishing geaxs axe used thexe (twawls, longmines, nets, purse seines). If the cod catches in Dirision Ita are divided by tishing geens and ixshery types, then the reliability of forecasting oatches in this axea would be considerably improved taking into account their age corposition.

Calculated total catches of cod and haddock from predicted equations are givea in Appendix Rable III. On the basis of the data irom this Table, Appendix Table TV was compiled.

Appendix Table IV shows the calculated catoh of cod and haddock by all countries at the existing level of fishing intensity and also vith a reduction of $20 \%$ in the fattening areas and on the spawning grounds, i.e over the whole axea inhabited by the cod stocks.

Appendix Table I. Young Cod Catch at the Third Year of Life (From Data of Autumn - Winter Investigations Undertaken by PTMR). Specimens per Hour Txawling.

| Year Class | Southern Barents Sea Sub-area 1 | NW Areas Division TIb | Whole Area |
| :---: | :---: | :---: | :---: |
