2. Terms of reference

At the 63rd Statutory Meeting of ICES a resolution (C.Res.1975/2:26) asked the Working Group to:
a) assess TACs for 1977 for cod and haddock;
b) having assessed the effective mesh size in current use, it should estimate the effects of further increase in mesh size for these species;
c) further examine the state of the stocks of Blue Ling, Ling and Redfish. To this end, countries are requested to submit further biological and statistical data on these species.
3. Description of fisheries

The description of the fisheries in the area in last year's report has been supplemented by a description of the French fishery, and this is given in the Appendix to this report.
4. State of the stocks
4.1. Cod (Plateau stock). The assessments have been made only for the Faroe Plateau stock as the data for Faroe Bank are not sufficiently good for a separate assessment to be made for that stock.

Catches from the Faroe Plateau increased to 36000 tons in 1975 compared with 25000 tons in 1974. Most of this increase was accounted for by the additional 9000 tons in the Faroese catch. It is believed that fishing effort rose approximately in proportion to the increase in landings.
4.1.1. Virtual population analysis (VPA). Age compositions of total catches used as imput data for the VPA are given in Table 13. (tabulations shown for 1966-1975 only). Calculated values of fishing mortality are shown in Table 14, together with the values assumed for 1975 which were used to initiate the computation. The assumed values for 1975 take into account the increase in fishing effort which has probably given rise to the higher catches in 1975. The corresponding estimates of stock size in the last ten years are given in Table 15. Estimates of year class strength are summarized in Table 16. The strength of recent year classes appear to have been close to the long-term average value.
4.1.2. Stock prognosis and calculations of Total Allowable Catches (TACs). In preparing the prognoses for. 1976-78 the Group considered that the increased level of fishing effort in 1975 was likely to be at least maintained and probably further increased in 1976. During 1973 and 1974 fishing mortality rates on cod were close to the level giving maximum yield per recruit for the present exploitation pattern, ( $F=0.45$ ) .

An increase in fishing mortality above about $F=0.45$ on the age groups subject to maximum exploitation will result in slightly reduced catches (in the long term), appreciably reduced catch rates, and a reduction in the size of the spawning stock biomass. The fishery will also become more dependent on the recruiting year classes and will tend to be subject to increasing fluctuations from year to year according to the variation in year class strength of the recruiting year classes. The Working Group considers that the fishing mortality level should be reduced to $F=0.45$ as soon as possible.

Prognoses have been prepared to show the effect on catches if (a) fishing mortality is maintained at the 1975 level ( $F=0.55$ ) over the period 1976. 78, (b) $F=0.6$ during 1976-78, (c) $F=0.65$ during 1976-78 (Table 20). The prognoses are based on the 1975 catch age composition data and exploitation pattern assumed for 1975 as given in Table 21 , where the weight-at-age data are also shown. The abundance of the recruiting 1975 and 1976 year classes has been taken as $19.5 \times 10^{6}$ which is the average strength for year classes 1957-73。

The actual catch taken in 1975 and this year's updated estimate of catches in 1976 are both substantially larger than estimates prepared last year when it was expected that for these two years the catches would be about 25000 tons. These differences are due to the increase in the amount of fishing which was not anticipated at the last meeting of the Group.

The higher catches at the higher levels of fishing are obtained only at the expense of fishing up the accumulated stock biomass. In all cases catches will decrease with time and they will tend towards the sustainable yields which are 26900 tons $(F=0.55), 26500$ tons $(F=0.6), 26200$ tons $(F=0.65)$. If these levels of fishing mortality are maintained in the long term, the effect on the spawning stock size, assuming that recruitment is maintained at the average level, will be as shown below:

| $F$ | Equilibrium spawning stock <br> biomass (tons) |
| :---: | :---: |
| 0.45 | 66500 |
| 0.55 | 53500 |
| 0.60 | 48000 |
| 0.65 | 44000 |

Two further prognoses have been prepared to indicate what catches could be expected in 1977 and 1978 if a reduction of $F$ to 0.45 was effected over one year or two years. Both prognoses assume that fishing mortality will have increased to $F=0.65$ in 1976. An immediate reduction in fishing mortality to $F=0.45$ in 1977 will result in a severe reduction in catch to 25500 tons compared with a likely catch of 38000 tons in 1976, with a subsequent small increase to 26000 tons in 1978. If the reduction is spread over two years $\left(F_{7} 6=0.65, F_{77}=0.55\right.$, and $\left.F_{78}=0.45\right)$ the sequence of catches will be 38000 tons, 30000 tons and 25000 tons. With the present exploitation pattern and average recruitment the sustainable yield at $F=0.45$ is 27500 tons.

The Working Group recommends that fishing mortality is reduced to $F=0.45$ and，in order to alleviate difficulties which would result from severe reductions in catch，that this reduction should be spread over two years． In addition to the catch from the Faroe Plateau an allowance of 2000 tons is made for catches from the Faroe Bank．Accordingly the TACs recommended by the Working Group for the whole of the Faroe area are as follows：

Recommended TACs for Cod

1977 （subject to revision） | 32000 tons |
| :--- |
| 1978000 tons |

4．1．3．Spawning stock biomass．Figure 1 shows the trend in observed spawning stock biomass of cod since 1960．The low levels in the early 1960＇s resulted from high exploitation levels in 1960 and 1961．Subsequently， fishing mortality was reduced and the spawning stock increased in size． Also indicated on the left－hand side of the figure are sizes of the equilibrium spawning stock associated with various specified values of $F$ assuming that recruitment is maintained at an average level．When the spawning stock was at a low level in the early l960＇s，there were no clear indications that recruitment was adversely affected．However，if fishing mortality is reduced to，and maintained at，$F=0.45$ this should ensure that the spawning stock will be maintained at a high level．The total stock bio－ mass will also be at a relatively high level providing associated economic benefits．

## 4．2 Haddock（total Division Vb）

Trends in catch and effort
The landings of haddock in 1974 were the lowest recorded in the last 20 years．This seems to reflect the poor recruitment in the late sixties．

Provisional data for 1975 indicate higher catches especially due to in－ creased effort by Faroese long－liners．

4．2．2 Estimates of mortality rates．The Virtual Population Analysis（VPA）of the haddock stock at Faroe was updated by including revised age frequency data for 1974 and provisional data for 1975.

Estimates of the total numbers landed in each age group were available for Faroese，Scottish and English catches．The age composition of the landings by other countries were estimated by raising the combined English and Scottish data（Table 17）。
No data for French landings for 1975 were at hand at the beginning of the meeting．It was，therefore，assumed that they were at the same level as in 1974 （ 1450 tons）and this figure was used in the raising procedure． Later on the French landing data arrived and showed that this was an under－ estimate，the provisional figures for 1975 being 2729 tons．The Group did not have time to rework the VPAs，but this underestimate should not seriously affect the estimates of TACs and the predicted catches．
The array of $F$ at age values for 1975 （last column of Table l8）were estimated from the corresponding array used in 1974 by raising by the ratio 1974 landings： 1975 landings．These changes gave rise to increased estimates of mortality rates for 1972 and 1973，especially for the younger age groups（Table 18）。 Stock sizes for the last ten years are given in Table 19。

| 4.2 .3 | Prognosis．Predictions of catches of Faroese haddock under various assumptions about fishing mortality rates are given in Table 20。（The input data for the predictions are shown in Table 21）．The Group assumed that the most likely value of the fishing mortality rates in 1975 on the age groups subject to maximum exploitation was $F=1.0$ 。 On this basis，assuming no change in $F$ during the next 3 years， catches are expected to increase slightly．The catches thus estimated for 1976 at this Working Group are higher than the corresponding value worked out last year because a higher value of $F$ was used and also because it now appears that the 1972 and 1973 year classes are relative－ ly large，although the estimate of the 1973 year class must be regarded as being less reliable。 <br> The Group was，however，of the opinion that fishing effort，and there－ fore the value of $F$ ，is likely to increase in 1976．The effect on catches over the next 3 years has been estimated for values of $F$ of 1.1 and 1.2 ，respectively．In both of these cases catches over the next 3 years are expected to increase．However，it was indicated in last yearls Report that a value of $F$ of 0.8 would result in a yield close to the maximum obtainable under the present pattern of exploitation．In addition，this value of $\bar{F}$ should，in the long term，allow the spawning stock of haddock to increase over present levels（see Figure 1）． |
| :---: | :---: |
| 4 | TACs for haddock．Because of the considerations referred to in the previous section，the Group thought it desirable to estimate a TAC which would tend to restore $F$ to a value of 0.8 ．Assuming that $F$ in 1976 will be l．2，the TAC required in 1977 to bring about an imme－ diate reduction to 0.8 would be about 20000 tons．This value，however， represents a considerable reduction in catch as compared to that expected in 1976． |
|  | For this reason the Group considered an alternative possibility of reducing $F$ to $\mathrm{l}_{0} 0$ in 1977 with a second reduction to 0.8 in 1978．In adopting this strategy，reductions in catch from year to year are lessened．The long－term catch with $F$ of 0.8 and assuming an average recruitment of $40 \times 10^{6} \mathrm{l}$ year olds is of the order of 23000 tons． The Group therefore recommends that the total allowable catch should be set as follows： |

## Recommended TACs for Haddock

1977 （subject to revision）$\quad 23000$ tons

## 4．3 Blue Ling and Ling

The Federal Republic of Germany，Norway and Faroe Islands split their ling catches by species and from 1974 onwards French data are also sub－ mitted．Thus，in 1974，90\％of the ling catches from the Faroes were split by species．Of this quantity blue ling made up about half．
Except for a few German（Federal Republic of）length measurements of blue ling，no biological data on these species have been collected and the knowledge of the stocks is practically nil．The catches have increased after 1971（Table 6）and German（Federal Republic of）data show a significant increase in catch per effort of blue ling after 1970 （Table 22），perhaps indicating an increase of the stock．
However，the blue ling is only a by－catch in the German（Federal Republic of）fishery for saithe and it is not known how reliable the catch per effort data on blue ling are．

| 4.4 | Redfish |
| :---: | :---: |
|  | A limited amount of age and length data on redfish was submitted to the Working Group by the representative of the Federal Republic of Germany. These data were considered inadequate for the purposes of stock assessment. Further progress in collecting adequate biological data will be complicated by the fact that, at least in the Federal Republic of Germany, redfish landings are not separated into species (응 marinus and So mentella). Furthermore, the fishery of the Federal Republic of Germany is seasonal in nature and for this reason it is sometimes impossible to obtain samples. |
| 4.5 | It is unlikely that the Working Group will be able to make any progress in the assessments of the stocks of Blue Ling, Ling and Redfish, until adequate data have been collected over a series of years. |
| 5. | Mesh Assessments |
|  | Data had been collected for the meeting of the Working Group on length composition of Faroese, Scottish and English landings for 1974 and provisional data for 1975, in order to estimate the effective mesh size in use in the area. |
|  | A method of calculating this has been elaborated by Mr K P Andersen of the Danish Institute of Marine and Fisheries Research. Unfortunately, due to illness Mr Andersen could not perform the calculations at this meeting. The calculations will be made later, based on the data brought to the meeting. |
|  | Having been unable to estimate the effective mesh size, the Group felt that nothing could be added to the previous mesh change assessments. |

## Recruitment

Average recruitment 1959-73 = 19500 assumed for year classes 1974-76 at 1 year old.

Average recruitment 1959-73 = 40000 assumed for year classes 1975 and 1976.

## APPENDIX

## Description of Fisheries at the Faroes

## The French fishery at Faroe

Estimations made by the "Institut des Pêches maritimes" indicate that there are about 50 trawlers of gross tonnage between 150 and 999 tons fishing the Faroe area regularly. In addition, there are probably about 100 trawlers which fish less regularly at Faroe. The gear generally used is a $35 / 55 \mathrm{~m}$ or 23 m Moisant bottom trawl. Generally, fishing takes place on the Faroe Plateau in the NW, N, NE and E of the Islands according to the availability of the open areas, but during April, May and June it moves a little towards the Faroe Bank (Appendix Tables 1 and 2).

In winter, spring and at the beginning of the summer, as soon as the saithe yields decrease in the ICES Divisions VIa and IVa, the larger trawlers transfer their effort to the Plateau.

Saithe is the main species sought and landings from Faroe constitute a quarter or more of the total French landings of this species. Other demersal species such as cod, haddock, whiting, tusk and plaice are taken in smaller quantities.
Second in importance is the fishery for blue ling, sought in the deep waters around the Faroe Bank, Lousy Bank and in the southwest of the Islands, during the whole of May.

Small quantities of redfish are caught to the east and the west of the Islands, all the year round,
The French statistical system, introduced in 1974, has not been in service sufficiently long to give a description of historical variation of fishing effort. It is known, however, that F'rench fishing effort at Faroe increased in 1975.
Appendix Table l. France 1974. Fishing effort and landings of selected species.
