ICES. 2011. Report of the Working Group on North Atlantic Salmon (WGNAS), 22-31 March 2011, Copenhagen, Denmark. ICES 2011/ACOM:09. 286 pp.

For permission to reproduce material from this publication, please apply to the General Secretary.

The document is a report of an Expert Group under the auspices of the International Council for the Exploration of the Sea and does not necessarily represent the views of the Council.

## Contents

Executive Summary .....  5
1 Introduction .....  6
1.1 Main tasks .....  6
1.2 Participants .....  9
1.3 Management framework for salmon in the North Atlantic ..... 10
1.4 Management objectives ..... 10
1.5 Reference points and application of precaution ..... 11
2 Atlantic salmon in the North Atlantic area ..... 12
2.1 Catches of North Atlantic Salmon ..... 12
2.1.1 Nominal catches of salmon ..... 12
2.1.2 Catch and release ..... 13
2.1.3 Unreported catches ..... 14
2.2 Farming and sea ranching of Atlantic salmon ..... 14
2.2.1 Production of farmed Atlantic salmon ..... 14
2.2.2 Harvest of ranched Atlantic salmon ..... 15
2.3 NASCO has asked ICES to report on significant, new or emerging threats to, or opportunities for, salmon conservation and management ..... 15
2.3.1 Update on Workshop on Age Determination of Salmon (WKADS) ..... 15
2.3.2 Overview of the potential impacts of the development of alternative/renewable energy on Atlantic salmon ..... 17
2.3.3 Overview of best solutions for fish passage with examples of practices in member countries ..... 20
2.3.4 Recent results from acoustic tracking investigations in Canada ..... 22
2.3.5 Assessing the impact of common assessment procedures on smolt physiology, behaviour and adult return rates ..... 23
2.3.6 Red vent syndrome ..... 25
2.3.7 Reduced sensitivity and development of resistance towards treatment in the salmon louse (Lepeophtheirus salmonis) ..... 26
2.3.8 Atlantic salmon genetics-new initiatives in relation to management of mixed-stock coastal fisheries in northern Norway ..... 26
2.3.9 SALSEA West Greenland ..... 27
2.3.10 Salmon bycatch in the Icelandic mackerel fishery ..... 28
2.3.11 Reintroduction of salmon-developments on the River Rhine ..... 28
2.4 NASCO has asked ICES to report on significant advances in our understanding of associations between changes in biological characteristics of all life stages of Atlantic salmon and ecosystem
changes with a view to better understanding the dynamics of salmon populations ..... 30
2.5 NASCO has asked ICES to further develop approaches to forecast pre-fishery abundance for North American and European stocks with measures of uncertainty ..... 30
2.6 NASCO has asked ICES to provide a review of examples of successes and failures in wild salmon restoration and rehabilitation and develop a classification of activities which could be recommended under various conditions or threats to the persistence of populations ..... 33
2.7 NASCO has asked ICES to provide a compilation of tag releases by country in 2010 and advise on the utility of maintaining this compilation ..... 33
2.7.1 Compilation of tag releases and fin clip data by ICES Member Countries in 2010 ..... 33
2.7.2 Utility of maintaining the tag compilation ..... 34
3 Northeast Atlantic Commission ..... 49
3.1 Status of stocks/exploitation ..... 49
3.2 Management objectives ..... 50
3.3 Reference points ..... 50
3.3.1 Description of the national conservation limits model ..... 50
3.3.2 National conservation limits ..... 51
3.3.3 Progress with setting river-specific conservation limits ..... 51
3.4 Management advice ..... 52
3.4.1 Northern NEAC maturing 1SW stock. ..... 52
3.4.2 Northern NEAC non-maturing 1SW stock ..... 52
3.4.3 Southern NEAC maturing 1SW stocks ..... 52
3.4.4 Southern NEAC non-maturing 1SW stocks ..... 53
3.5 Relevant factors to be considered in management ..... 53
3.5.1 Grouping of national stocks ..... 53
3.6 Pre-fishery abundance forecasts ..... 54
3.6.1 Description of the forecast model ..... 54
3.6.2 Results of the NEAC Bayesian forecast models ..... 55
3.6.3 Probability of attaining PFA above SER ..... 56
3.6.4 Use of the NEAC Bayesian forecast models in catch advice. ..... 56
3.7 Comparison with previous assessment ..... 56
3.7.1 Changes to the NEAC PFA model and national conservation limit model ..... 56
3.7.2 Changes to the NEAC PFA Bayesian forecast model ..... 57
3.7.3 Performance of the revised 2011 Bayesian forecast model ..... 58
3.8 NASCO has requested ICES to describe the key events of the 2010 fisheries and the status of the stocks ..... 59
3.8.1 Fishing at Faroes in 2009/2010 ..... 59
3.8.2 Significant events in NEAC homewater fisheries in 2010 ..... 59
3.8.3 Gear and effort ..... 60
3.8.4 Catches ..... 60
3.8.5 Catch per unit of effort (cpue) ..... 61
3.8.6 Age composition of catches ..... 61
3.8.7 Farmed and ranched salmon in catches ..... 62
3.8.8 National origin of catches ..... 62
3.8.9 Developments to the NEAC-PFA and CL model ..... 63
3.8.10 National input to the NEAC-PFA model ..... 63
3.8.11 Description of national stocks as derived from the PFA model ..... 64
3.8.12 Trends in the PFA for NEAC stocks ..... 64
3.8.13 Survival indices for NEAC stocks ..... 65
3.8.14 Exploitation indices for NEAC stocks ..... 66
3.9 NASCO has asked ICES to further investigate opportunities to develop a framework of indicators or alternative methods that could be used to identify any significant change in previously provided multi-annual management advice ..... 67
3.10 NASCO has asked ICES to provide a more detailed evaluation of the choice of appropriate management units to be used in a risk based framework for the provision of catch advice for the Faroese salmon fishery, taking into account relevant biological and management considerations and including, if possible, worked examples of catch advice ..... 68
3.10.1 Background ..... 68
3.10.2 Faroes fishing season ..... 69
3.10.3 Choice of management units ..... 69
3.10.4 Management objectives ..... 71
3.10.5 Sharing agreement ..... 71
3.10.6 Evaluation of catch options ..... 72
3.10.7 Input data for the risk framework ..... 73
3.10.8 Worked example of the risk framework ..... 74
4 North American commission ..... 135
4.1 Status of stocks/exploitation ..... 135
4.2 Management objectives ..... 135
4.3 Reference points ..... 135
4.4 NASCO has requested ICES to describe the key events of the 2010 fisheries ..... 135
4.4.1 Key events of the 2010 fisheries ..... 135
4.4.2 Harvest of North American salmon, expressed as 2SW salmon equivalents ..... 136
4.4.3 Gear and effort ..... 136
4.4.4 Catches in 2010 ..... 138

## Executive Summary

Working Group on North Atlantic Salmon [WGNAS], ICES HQ, 22-31 March 2011. Chair: Gérald Chaput (Canada).

Number of participants: 24 representing fourteen nations from North America and the Northeast Atlantic. Information was provided by correspondence from Greenland and Spain, for use by the Working Group.

WGNAS met to consider questions posed to ICES by the North Atlantic Salmon Conservation Organization (NASCO) and by ICES Science Committee and the Chair of the Advisory Committee. The terms of reference were addressed by reviewing working documents prepared ahead of the meeting as well as the development of documents and text for the report during the meeting.

The Report is structured by sections specific to the terms of reference of the WGNAS.
Relative to the questions posed by NASCO:

- In the North Atlantic, exploitation remains low and nominal catch of wild Atlantic salmon in 2010 was 1589 t, the third lowest in the time-series beginning in 1960.
- Northern Northeast Atlantic Commission stock complexes (1SW and MSW) are at full reproductive capacity prior to the commencement of distant water fisheries.
- Southern Northeast Atlantic Commission stock complexes (1SW and MSW) are at full reproductive capacity prior to the commencement of distant water fisheries.
- Prior to any distant water fisheries, the 1SW age group in the Northern NEAC and both age groups in the Southern NEAC stock complexes are at risk of suffering reduced reproductive capacity for 2011 to 2014. The MSW age group from the Northern NEAC complex is at full reproductive capacity for 2011 and 2012 and at risk of suffering reduced reproductive capacity in 2013 and 2014.
- Marine survival indices in the North Atlantic have declined and remain low. Factors other than marine fisheries, acting in freshwater and in the ocean in both NAC and NEAC (marine mortality, fish passage, water quality), are contributing to continued low abundance of wild Atlantic salmon.
- The Working Group has provided a work example of the catch advice framework for the Faroes Fishery. Further, a proposed Framework of Indicator framework for the Faroes fishery is provided.

Relative to the question posed by ICES:

- Elements from WGNAS specific to population abundance and status relative to safe biological limits for Atlantic salmon are contained in WGNAS reports and could be considered by MSFDG in delivery of their tasks. As well, information reviewed by WGNAS regularly and contained in numerous study group and workshop initiatives could be used by Strategic Initiative on Area Based Science and Management (SIASM) to develop advice on marine area based management and spatial planning.

### 1.1 Main tasks

At its 2010 Statutory Meeting, ICES resolved (C. Res. 2010/2/ACOM09) that the Working Group on North Atlantic Salmon [WGNAS] (chaired by: Gérald Chaput, Canada) will meet at ICES HQ, 22-31 March 2011 to consider questions posed to ICES by the North Atlantic Salmon Conservation Organization (NASCO). In March 2011, NASCO also asked ICES to provide a more detailed evaluation of the choice of appropriate management units to be used in a risk based framework for the provision of catch advice for the Faroese salmon fishery, taking into account relevant biological and management considerations and including, if possible, worked examples of catch advice.

In a communication dated March 10, 2011, the Chair of the ICES Science Committee and the Chair of the Advisory Committee requested assistance from ICES expert groups to two groups created jointly by ACOM and SCICOM, the Marine Strategy Directive Framework Steering Group (MSDFSG) and the Strategic Initiative on Area Based Science and Management (SIASM).

The terms of reference were met and the sections of the report which provide the answers are identified below:

| a) | With respect to Atlantic Salmon in the North Atlantic area: | Section <br> 2 |
| :---: | :---: | :---: |
| i)Provide an overview of salmon catches and landings, in- <br> cluding unreported catches by country and catch and re- <br> lease, and production of farmed and ranched Atlantic <br> salmon in 20101 | 2.1 and <br> 2.2 |  |
| ii)report on significant new or emerging threats to, or oppor- <br> tunities for, salmon conservation and management²; | 2.3 |  |
| iii)Report on significant advances in our understanding of as- <br> sociations between changes in biological characteristics of all <br> life stages of Atlantic salmon and ecosystem changes with a <br> view to better understanding the dynamics of salmon popu- <br> lations ${ }^{3}$ | 2.4 |  |
| iv)Further develop approaches to forecast pre-fishery abun- <br> dance for North American and European stocks with meas- <br> ures of uncertainty; | 2.5 |  |
| v)Provide a review of examples of successes and failures in <br> wild salmon restoration and rehabilitation and develop a <br> classification of activities which could be recommended un- <br> der various conditions or threats to the persistence of popu- <br> lations; ${ }^{4}$ | 2.6 |  |
| vi) Provide a compilation of tag releases by country in 2010 and |  |  |
| advise on the utility of maintaining this compilation; |  |  |

b) With respect to Atlantic salmon in the Northeast Atlantic Com- Section mission area:

1) Describe the key events of the 2010 fisheries; ..... 3.8
2 ) Review and report on the development of age-specific stock ..... 3.3conservation limits;
3 ) Describe the status of the stocks and provide annual catch ..... 3.1, 3.2,
options or alternative management advice for 2012-2014, ..... 3.4, 3.5,
with an assessment of risks relative to the objective of ex- ..... 3.6, 3.7,
ceeding stock conservation limits and advise on the implica- ..... 3.8.9 to
tions of these options for stock rebuilding; ..... 3.8.15,

- supplementary request from NASCO received March 9 2011: "Provide a more detailed evaluation of the choice of appropriate management units to be used in a risk based framework for the provision of catch advice for the Faroese salmon fishery, taking into account relevant biological and management considerations and including, if possible, worked examples of catch advice."
4 ) Further investigate opportunities to develop a framework of ..... 3.9
indicators or alternative methods that could be used to iden
tify any significant change in previously provided multi
annual management advice.

c) With respect to Atlantic salmon in the North American Com
mission area:
1 ) Describe the key events of the 2010 fisheries (including the ..... 4.4 fishery at St Pierre and Miquelon) ${ }^{5}$;
2 ) Update age-specific stock conservation limits based on new ..... 4.3 information as available;
3 ) Describe the status of the stocks; ..... 4.1, 4.5,

- In the event that NASCO informs ICES that the framework of indicators (FWI) indicates that reassessment is required ${ }^{8}$ :

4 ) Provide annual catch options or alternative management advice for 2011-2014 with an assessment of risks relative to the objective of exceeding stock conservation limits and advise on the implications of these options for stock rebuilding ${ }^{6}$.

d) With respect to Atlantic salmon in the West Greenland Commis
Section
5
sion area:
5.1

1) Describe the key events of the 2010 fisheries ${ }^{5}$; ..... 5.2

- In the event that NASCO informs ICES that the framework of indicators (FWI) indicates that reassessment is required ${ }^{8}$ :

3 ) Provide annual catch options or alternative management advice for 2011-2013 with an assessment of risk relative to the objective of exceeding stock conservation limits and advise on the implications of these options for stock rebuilding ${ }^{6}$.
e) ICES Science Committee and the Chair of the Advisory Committee requested assistance from ICES expert groups to two groups created jointly by ACOM and SCICOM, the Marine Strategy Directive Framework Steering Group (MSDFSG) and the Strategic Initiative on Area Based Science and Management (SIASM).

1) ICES requested all its Expert Groups (EG) to identify and describe the work streams of relevance to the Descriptors in Annex I of Directive 2008/56/EC regarding criteria for good environmental status of marine waters. EGs are asked to provide views on what good environmental status might be for those descriptors, including methods that could be used to determine status.
2) From SIASM, the following term of reference were added to all EGs for 2011:
i. take note of and comment on the Report of the Workshop on the Science for area-based management: Coastal and Marine Spatial Planning in Practice (WKCMSP)
ii. provide information that could be used in setting pressure indicators that would complement biodiversity indicators currently being developed by the Strategic Initiative on Biodiversity Advice and Science (SIBAS). Particular consideration should be given to assessing the impacts of very large renewable energy plans with a view to identifying/predicting potentially catastrophic outcomes.
iii. identify spatially resolved data, for e.g. spawning grounds, fishery activity, habitats, etc.

Notes:

1. With regard to question a.1, for the estimates of unreported catch the information provided should, where possible, indicate the location of the unreported catch in the following categories: in-river; estuarine; and coastal.
2. With regard to question a.2, ICES is requested to include information on any new research into the migration and distribution of salmon at sea and on the potential impacts of the development of alternative/renewable energy on Atlantic salmon.
3. With regard to question a.3, there is particular interest in determining if declines in salmon abundance coincide with changes in the biological characteristics of juveniles in freshwater or are modifying characteristics of adult fish (size at age, age at maturity, condition, sex ratio, growth rates, etc.) and with environmental changes including climate change
4. With regard to question a.5, ICES is requested to include information on best solutions for fish passage and associated mitigation efforts with examples of practices in member countries.
5. In the responses to questions b.1, c. 1 and d.1, ICES is asked to provide details of catch, gear, effort, composition and origin of the catch and rates of exploitation. For homewater fisheries, the information provided should indicate the location of the catch in the
following categories: in-river; estuarine; and coastal. Any new information on non-catch fishing mortality, of the salmon gear used, and on the bycatch of other species in salmon gear, and on the bycatch of salmon in any existing and new fisheries for other species is also requested.
6. In response to questions b.3, c. 4 and d.3, provide a detailed explanation and critical examination of any changes to the models used to provide catch advice
7. In response to question d.2, ICES is requested to provide a brief summary of the status of North American and Northeast Atlantic salmon stocks. The detailed information on the status of these stocks should be provided in response to questions b. 3 and c.3.

8 The aim should be for NASCO to inform ICES by 31 January of the outcome of utilizing the FWI

At the 2009 Annual Meeting of NASCO, conditional multi-annual regulatory measures were agreed to in the West Greenland Commission (2009-2011) and for the Faroe Islands (2009-2011) in the Northeast Atlantic Commission. The measures were conditional on a Framework of Indicators (FWI) being provided by ICES, and the acceptance of the FWI by the various parties of each commission. At the 2009 annual meeting of NASCO, Denmark (in respect of the Faroe Islands) opted out of the multiannual regulatory measures as a FWI was not provided by ICES for the fishery in the Faroes (ICES, 2010b). In January 2011, NASCO indicated that no change to the management advice previously provided by ICES was required for the fishery at West Greenland.

In response to the remaining terms of reference, the Working Group considered 33 Working Documents submitted by participants (Annex 1); other references cited in the Report are given in Annex 2. A full address list for the participants is provided in Annex 3. A complete list of acronyms used within this document is provided in Annex 7.

### 1.3 Management framework for salmon in the North Atlantic

The advice generated by ICES is in response to terms of reference posed by the North Atlantic Salmon Conservation Organization (NASCO), pursuant to its role in international management of salmon. NASCO was set up in 1984 by international convention (the Convention for the Conservation of Salmon in the North Atlantic Ocean), with a responsibility for the conservation, restoration, enhancement, and rational management of wild salmon in the North Atlantic. While sovereign states retain their role in the regulation of salmon fisheries for salmon originating from their own rivers, distant water salmon fisheries, such as those at Greenland and Faroes, which take salmon originating from rivers of another Party are regulated by NASCO under the terms of the Convention. NASCO now has six Parties that are signatories to the Convention, including the EU which represents its Member States.

NASCO discharges these responsibilities via three Commission areas shown below:

### 1.4 Management objectives

NASCO has identified the primary management objective of that organization as:
"To contribute through consultation and cooperation to the conservation, restoration, enhancement and rational management of salmon stocks taking into account the best scientific advice available".

NASCO further stated that "the Agreement on the Adoption of a Precautionary Approach states that an objective for the management of salmon fisheries is to provide the diversity and abundance of salmon stocks" and NASCOs Standing Committee on the Precautionary Approach interpreted this as being "to maintain both the productive capacity and diversity of salmon stocks" (NASCO 1998).

NASCO's Action Plan for Application of the Precautionary Approach (NASCO 1999) provides interpretation of how this is to be achieved, as follows:

- "Management measures should be aimed at maintaining all stocks above their conservation limits by the use of management targets".
- "Socio-economic factors could be taken into account in applying the Precautionary Approach to fisheries management issues".
- "The precautionary approach is an integrated approach that requires, inter alia, that stock rebuilding programmes (including as appropriate, habitat improvements, stock enhancement, and fishery management actions) be developed for stocks that are below conservation limits".

### 1.5 Reference points and application of precaution

Conservation limits (CLs) for North Atlantic salmon stock complexes have been defined by ICES as the level of stock (number of spawners) that will achieve longterm average maximum sustainable yield (MSY). In many regions of North America, the CLs are calculated as the number of spawners required to fully seed the wetted area of the river. In some regions of Europe, pseudo stock-recruitment observations are used to calculate a hockey stick relationship, with the inflection point defining the CLs. In the remaining regions, the CLs are calculated as the number of spawners that will achieve long-term average maximum sustainable yield (MSY), as derived from the adult-to-adult stock and recruitment relationship (Ricker, 1975; ICES, 1993). NASCO has adopted the region specific CLs (NASCO 1998). These CLs are limit reference points ( $\mathrm{S}_{\mathrm{lim}}$ ); having populations fall below these limits should be avoided with high probability.

Management targets have not yet been defined for all North Atlantic salmon stocks. When these have been defined they will play an important role in ICES advice.

For the assessment of the status of stocks and advice on management of national components and geographical groupings of the stock complexes in the NEAC area, where there are no specific management objectives:

- ICES requires that the lower bound of the $95 \%$ confidence interval of the current estimate of spawners is above the CL for the stock to be considered at full reproductive capacity.
- When the lower bound of the confidence limit is below the CL, but the midpoint is above, then ICES considers the stock to be at risk of suffering reduced reproductive capacity.
- Finally, when the midpoint is below the CL, ICES considers the stock to suffer reduced reproductive capacity.

It should be noted that this is equivalent to the ICES precautionary target reference points $\left(\mathrm{S}_{\mathrm{pa}}\right)$. Therefore, stocks are regarded by ICES as being at full reproductive capacity only if they are above the precautionary target reference point. This approach parallels the use of precautionary reference points used for the provision of catch advice for other fish stocks in the ICES area.

For catch advice on fish exploited at West Greenland (non maturing 1SW fish from North America and non maturing 1SW fish from Southern NEAC), ICES has adopted, a risk level of $75 \%$ (ICES, 2003) as part of an agreed management plan. ICES applies the same level of risk aversion for catch advice for homewater fisheries on the North American stock complex.

## 2 Atlantic salmon in the North Atlantic area

### 2.1 Catches of North Atlantic Salmon

### 2.1.1 Nominal catches of salmon

The nominal catch of a fishery is defined as the round, fresh weight of fish that are caught and retained. Total nominal catches of salmon reported by country in all fisheries for 1960-2010 are given in Table 2.1.1.1. Catch statistics in the North Atlantic also include fish-farm escapees and, in some Northeast Atlantic countries, ranched fish (see Section 2.2.2). Catch and release has become increasingly commonplace in some countries, but these fish do not appear in the nominal catches (see Section 2.1.2).

Icelandic catches have traditionally been split into two categories, wild and ranched, reflecting the fact that Iceland has been the only North Atlantic country where largescale ranching has been undertaken with the specific intention of harvesting all returns at the release site. The release of smolts for commercial ranching purposes ceased in Iceland in 1998, but ranching for rod fisheries in two Icelandic rivers continued into 2010 (Table 2.1.1.1). While ranching does occur in some other countries, this is on a much smaller scale. Some of these operations are experimental and at others harvesting does not occur solely at the release site. The ranched component in these countries has therefore been included in the nominal catch.

Figure 2.1.1.1 shows the total reported nominal catch of salmon grouped by the following areas: 'Northern Europe' (Norway, Russia, Finland, Iceland, Sweden and Denmark); 'Southern Europe' (Ireland, UK (Scotland), UK (England and Wales), UK (Northern Ireland), France and Spain); 'North America' (Canada, USA and St Pierre et Miquelon (France)); and 'Greenland and Faroes'.

The provisional total nominal catch for 2010 was 1589 tonnes, 276 t above the updated catch for $2009(1313 \mathrm{t})$. The 2010 catch was 164 t below the average of the last five years ( 1753 t ), and over 600 t below the average of the last ten years ( 2201 t ). Catches were below the previous five- and ten-year averages in the majority of Southern NEAC countries except UK (England and Wales) and UK (Scotland) where catches in 2010 were above the previous five-year averages. Catches were below the previous ten-year averages and above the previous five-year averages in the majority of Northern NEAC countries.

Nominal catches in homewater fisheries split, where available, by sea age or size category are presented in Table 2.1.1.2 (weight only). The data for 2010 are provisional and, as in Table 2.1.1.1, include both wild and reared salmon and fish-farm escapees in some countries. A more detailed breakdown, providing both numbers and weight for different sea age groups for most countries, is provided at Annex 4. Countries use different methods to partition their catches by sea age class (outlined in the footnotes to Annex 4). The composition of catches in different areas is discussed in more detail in Sections 3, 4, and 5.

ICES recognizes that mixed-stock fisheries present particular threats to stock status. These fisheries predominantly operate in coastal areas and NASCO specifically requests that the nominal catches in homewater fisheries be partitioned according to whether the catch is taken in coastal, estuarine or riverine areas. Figure 2.1.1.2 presents these data on a country-by-country basis. It should be noted, however, that the way in which the nominal catch is partitioned among categories varies between countries, particularly for estuarine and coastal fisheries. For example, in some countries
these catches are split according to particular gear types and in other countries the split is based on whether fisheries operate inside or outside headlands. While it is generally easier to allocate the freshwater (riverine) component of the catch, it should also be noted that catch and release is now in widespread use in several countries (Section 2.1.2) and these fish are excluded from the nominal catch. Noting these caveats, these data are considered to provide the best available indication of catch in these different fishery areas. Figure 2.1.1.2 shows that there is considerable variability in the distribution of the catch among individual countries. In most countries the majority of the catch is now taken in freshwater; the coastal catch has declined markedly.

Coastal, estuarine and riverine catch data aggregated by region are presented in Figure 2.1.1.3. In northern Europe catches in coastal fisheries have been in decline since 2001 and freshwater catches have been relatively constant. About half the catch has typically been taken in rivers and half in coastal waters (although there are no coastal fisheries in Iceland and Finland), with estuarine catches representing a negligible component of the catch in this area. There has been a reduction in the proportion of the catch taken in coastal waters over the last five years and it now represents only one third of the total. In southern Europe, catches in all fishery areas have declined dramatically over the period. While coastal fisheries have historically made up the largest component of the catch, these fisheries have declined the most, reflecting widespread measures to reduce exploitation in a number of countries. In the last four years, the majority of the catch in this area has been taken in freshwater, though there was a slight increase in the proportion of the catch taken in coastal waters in 2010.

In North America, the total catch over the period 2000 to 2010 has been relatively constant. The majority of the catch in this area has been taken in riverine fisheries; the catch in coastal fisheries has been relatively small in any year ( 13 t or less), but has increased as a proportion of the total catch over the period.

### 2.1.2 Catch and release

The practice of catch and release in rod fisheries has become increasingly common as a salmon management/conservation measure in light of the widespread decline in salmon abundance in the North Atlantic. In some areas of Canada and USA, catch and release has been practiced since 1984, and in more recent years it has also been widely used in many European countries both as a result of statutory regulation and through voluntary practice.

The nominal catches presented in Section 2.1.1 do not include salmon that have been caught and released. Table 2.1.2.1 presents catch-and-release information from 1991 to 2010 for countries that have records. Catch and release may also be practiced in other countries while not being formally recorded. There are large differences in the percentage of the total rod catch that is released: in 2010 this ranged from $12 \%$ in Norway (this is a minimum figure) to $70 \%$ in UK (Scotland) reflecting varying management practices and angler attitudes among these countries. Catch and release rates have typically been highest in Russia (average of $84 \%$ in the five years 2004 to 2008) and are believed to have remained at this level. However, there were no obligations to report caught-and-released fish in Russia in 2009 and records for 2010 are incomplete. Within countries, the percentage of fish released has tended to increase over time. There is also evidence from some countries that larger MSW fish are released in larger proportions than smaller fish. Overall, over 222000 salmon were reported to have been released around the North Atlantic in 2010, the highest in the time-series.

Summary information on how catch and release levels are incorporated into national assessments was provided to the Working Group in 2010 (ICES 2010b).

### 2.1.3 Unreported catches

Unreported catches by year (1987 to 2010) and Commission Area are presented in Table 2.1.3.1 and are presented relative to the total nominal catch in Figure 2.1.3.1. A description of the methods used to derive the unreported catches was provided in ICES (2000) and updated for the NEAC Region in ICES (2002). Detailed reports from different countries were also submitted to NASCO in 2007 in support of a special session on this issue. There have been no estimates of unreported catch for Russia since 2008 and for Canada in 2007 and 2008. Estimates for Canada since 2009 are considered incomplete (information available for three of the four jurisdictions). There are also no estimates of unreported catch for Spain and St Pierre and Miquelon (NAC), where total catches are typically small. It has not been possible to separate the unreported catch into that taken in coastal, estuarine and riverine areas.

In general, the derivation methods used by each country have remained relatively unchanged and thus comparisons over time may be appropriate. However, the estimation procedures vary markedly between countries. For example, some countries include only illegally caught fish in the unreported catch, while other countries include estimates of unreported catch by legal gear as well as illegal catches in their estimates. Over recent years efforts have been made to reduce the level of unreported catch in a number of countries (e.g. through improved reporting procedures and the introduction of carcass tagging and logbook schemes).

The total unreported catch in NASCO areas in 2010 was estimated to be 382 t . The unreported catch in the Northeast Atlantic Commission Area in 2010 was estimated at 357 t , and that for the West Greenland and North American Commission Areas at 10 t and 15 t , respectively. The 2010 unreported catch by country is provided in Table 2.1.3.2 Information on unreported catches was not provided to enable these to be partitioned into coastal, estuarine and riverine areas.

In the past, salmon fishing by non-contracting parties is known to have taken place in international waters to the north of the Faroe Islands. Typically, a number of surveillance flights have taken place over this area in recent years and no sightings of vessels were reported, although there have been extended periods over the winter period when no flights took place. This is the period when salmon fishing has previously been reported. In 2010, there were no flights over the area by the Icelandic coastguard. Some flights are thought to have been completed by the Norwegian coastguard, but there is no information available on these.

Summary information on how unreported catches are incorporated into national and international assessments was provided to the Working Group in 2010 (ICES 2010b).

### 2.2 Farming and sea ranching of Atlantic salmon

### 2.2.1 Production of farmed Atlantic salmon

The provisional estimate of farmed Atlantic salmon production in the North Atlantic area for 2010 is 1177 kt , the second year in which production in this area has been in excess of one million tonnes. The 2010 total represents a $5 \%$ increase on 2009 and a $26 \%$ increase on the previous 5 -year mean (Table 2.2.1.1 and Figure 2.2.1.1) due to increased production in the majority of countries where farming occurs. Norway and

UK (Scotland) continue to produce the majority of the farmed salmon in the North Atlantic ( $78 \%$ and $13 \%$ respectively).

Worldwide production of farmed Atlantic salmon has been over one million tonnes since 2002. It is difficult to source reliable production figures for all countries outside the North Atlantic area and it has been necessary to use 2009 estimates for some countries in deriving a worldwide estimate for 2010. Noting this caveat, total production in 2010 is provisionally estimated at around 1369 kt (Table 2.2.1.1 and Figure 2.2.1.1), a $4 \%$ decrease on 2009, continuing the small decrease in production first noted in 2009 and reflecting a fall in production outside the North Atlantic in 2010. Production in this area is estimated to have accounted for $14 \%$ of the total in 2010 (down from $22 \%$ in 2009 and $34 \%$ in 2008). Production outside the North Atlantic is still dominated by Chile despite a further decrease in farmed salmon production in this country compared with 2009 (60\%) due to an outbreak of infectious salmon anaemia (ISA) virus. The ISA outbreak is reported to have had a catastrophic impact on the Chilean salmon industry.

The worldwide production of farmed Atlantic salmon in 2010 was over 850 times the reported nominal catch of Atlantic salmon in the North Atlantic.

### 2.2.2 Harvest of ranched Atlantic salmon

Ranching has been defined as the production of salmon through smolt releases with the intent of harvesting the total population that returns to freshwater (harvesting can include fish collected for broodstock) (ICES 1994). The release of smolts for commercial ranching purposes ceased in Iceland in 1998, but ranching with the specific intention of harvesting by rod fisheries has been practiced in two Icelandic rivers since 1990 and these data have now been included in the ranched catch (Table 2.1.1.1). The total harvest of ranched Atlantic salmon in countries bordering the North Atlantic in 2010 was 39 t , the majority of which ( 36 t ) was taken by the Icelandic ranched rod fisheries (Figure 2.2.2.1). Small catches of ranched fish from experimental projects were also recorded in Ireland; these data include catches in net, trap and rod fisheries. No estimate of ranched salmon production was made in Norway in 2010 where such catches have been very low in recent years ( $<1 \mathrm{t}$ ) and UK ( N . Ireland) where the proportion of ranched fish was not assessed between 2008 and 2010 due to a lack of microtag returns.

It was noted that a large proportion of the fish caught in Sweden in recent years ( 15 t , $70 \%$ of the total catch in 2010) originate from hatchery-reared smolts released under programmes to mitigate for hydropower development schemes. However, these fish do not fall within the agreed definition of ranched fish and are not included in Figure 2.2.2.1.

### 2.3 NASCO has asked ICES to report on significant, new or emerging threats to, or opportunities for, salmon conservation and management

### 2.3.1 Update on Workshop on Age Determination of Salmon (WKADS)

The Working Group noted that a Workshop on Age Determination of Salmon (WKADS) had recently taken place in Galway, Ireland (January 18th to 20th, 2011) with the objectives of reviewing, assessing, documenting and making recommendations on current methods of ageing Atlantic salmon. The Workshop had primarily focused on digital scale reading to measure age and growth, with a view to standardization.

Recommendations from the Workshop included standardizing digital scale reading, compilation of a digital image reference collection, detailing of characteristics and reference points, itemising scale marks and issues in their separation. Approaches to future sample and data collection to address questions of changing life histories and proposals for future data analyses were also made.
The Workshop began with presentations detailing reasons for scale reading and the procedures used by different laboratories, a theoretical review and practical demonstrations. Notable variations were found in the approaches taken by different laboratories. The most prevalent issues were presented and discussed in working sessions to reach consensus on how they should be addressed and the necessary steps to provide further information about them.

The previous report "No. 188 Atlantic Salmon Scale Reading Guidelines" (ICES 1992) was confirmed as the primary reference for practitioners. As such its definitions are still appropriate and so were adopted, though technology has moved forward enabling greater detailing in measurements and image storage. Groups in the working sessions detailed:

- The procedure of digital scale reading being adopted by the Celtic Sea Trout Project (Poole, 2010) was considered appropriate to reading salmon scales and should be adopted.
- A digital image reference collection was compiled to include recognized scale features and age groups.
- Scale spawning marks and erosion marks, commonly acknowledged as being difficult to recognize, were detailed.
- Scales from farm escapees were noted as being recently more complex to distinguish from those of wild salmon than in the past. The other common distinguishing marks were listed and should include morphology.
- Important reference points on scales were listed for accurate calculation of growth periods with digital apparatus.
- Approaches to data analyses being used on the more detailed datasets being collated from digital scale reading were presented and discussed.
- Approaches for determining changes in growth and life histories from scales were discussed and recommendations were made for the necessary data collection.
- In Northern Europe (Finland and Norway) collecting scale samples from an alternative position below the adipose fin was found to provide more information; this location is further back on the fish than recommended in the earlier scale reading guidelines (ICES 1992). A recommendation for future collection from this alternative position requires further consideration, owing to the long history of using the 'recognized' sampling location. Switching could undermine the continuity of the time-series.

On the basis of the draft Workshop output, the Working Group recommended that:

- further work be undertaken to address the issues raised at the Workshop regarding protocols, inter-laboratory calibration and quality control as they relate to the interpretation of age and calculation of growth and other features from scales;
- a second Workshop should be convened to facilitate the work and reporting.

### 2.3.2 Overview of the potential impacts of the development of alternative/renewable energy on Atlantic salmon

Globally, there has been increasing interest in recent years in the development of renewable energy sources. Renewable (naturally replenished) energy is that which comes from sources such as sunlight, wind, water, geothermal heat and biofuels. The growth of clean renewable energy has been seen as an important part of addressing climate change concerns. Together with high oil prices and an increasing awareness of the need for energy security, these concerns have led to increased levels of government support, renewable energy legislation, incentives and commercialization. Thus, governments have been keen to support the development of renewable energy technologies and to see the establishment of new renewable energy schemes.

Where such technologies rely on water power (river flow, tidal currents) or are located in aquatic environments, they have the potential to affect Atlantic salmon and other resident fish species. There are several forms of hydropower. Hydroelectric energy is a term usually associated with large-scale hydroelectric dams, but there are also many hydro systems which operate at a smaller, local scale. These might also rely on a head of water created by a dam or estuarine barrage to generate power, but hydroelectricity systems can also derive kinetic energy from rivers and oceans without using a dam. Tides, currents and waves can all be harnessed to produce power. For example, systems to harvest electrical power from ocean waves have recently been gaining momentum as a viable technology.

The development of renewable energy is expected to assist in the effort to reduce carbon emissions worldwide. However, this development raises particular concerns given that the impacts of past hydroelectric power developments on the natural environment and biodiversity have frequently not been adequately addressed or mitigated. Further, many new developments have not been properly evaluated, in part because many of the devices have yet to be deployed and tested (Boehlert and Gill, 2010).

The potential impacts of in-river and estuarine structures on Atlantic salmon are relatively well known given the long history of hydropower development and barrage construction in rivers supporting salmonid and other migratory fish species. Key concerns associated with such schemes are:

- The loss of juvenile habitat due to impoundment of the best spawning and rearing areas. The impounded areas created are commonly also colonized by species that favour those conditions, which result in additional pressures through predation and competition.
- The creation of barriers to migration prevents fish from reaching spawning areas and completing downstream migrations. This can be mitigated where sufficient water flows over a weir, or through an adjacent fish pass, providing appropriate conditions for fish. The position of fish passes in relation to the location of a hydropower scheme, as well as the fish pass type and flow conditions are critically important to the effectiveness of the pass. Fish passage options are discussed in more detail in the next section.
- Barriers also delay movements of migratory fish, reducing or removing the environmental cues that fish rely on during their migration. This can result in unnatural aggregations of fish in the vicinity of obstructions, with associated increased risks of predation, disease or exploitation.
- Where schemes rely on water being abstracted above a barrier or impoundment and discharged below it, the area of river between these points becomes depleted. This, in turn, can affect the channel morphology of the stretch with consequences for both migratory and resident species.
- The presence of side streams or mill leats that take water away from the main river channel disorientate migratory fish. Unless efficient fish passes are provided, this results in fish failing to complete their migration (up or down) and therefore being lost to the stock.
- The turbines (used to generate power) represent a very serious threat to migratory fish. Even with the most fish-friendly designs, fish mortalities occur when fish pass through the turbines. Such impacts can be partially mitigated by screening and provision of by-pass facilities. Screens and bypasses must be properly designed, positioned, operated and maintained.
- Key concerns relating to the impact of hydropower schemes on migratory fish are the construction of high dams in the lower sections of rivers and estuaries and the potential cumulative impact where a number of schemes are created in the same catchment. In such circumstances, it is critical that fish are able to enter the river and migrate successfully past successive barriers. The expansion of hydropower schemes needs to be considered at the catchment scale and not just the local scale.

The Working Group noted reports from several countries of an increase in the number of hydropower schemes in recent years, and that this was anticipated to increase further in coming years in response to government targets on renewable energy and the introduction of financial incentives to support this growth. For example, France has scheduled a power increase of 3000 MW by 31 December 2020 and a production increase of 3 million MWh per year, from hydropower developments. These targets represent an increase of $38 \%$ of the power and $21 \%$ of the production currently being generated in the salmon-producing areas in France. Regional planning and development of renewables is required in France and it is anticipated that hydropower developments will require revisions of river classification, possibly downward. French law on energy has ruled that all environmental measures (e.g. restoration projects or mitigation measures) have to be preceded by a socio-economic study of the impact on hydroelectric potential.

The Working Group noted apparent contradictions between the objectives of different EU Directives: Renewable Energy Directive (2009/28) seeks to promote the development of hydroelectric schemes, while the Council Directive on the Conservation of Natural Habitats and Wild Fauna and Flora (1992/43) and the Water Framework Directive (2000/60) seek to protect the functionality and resiliency of rivers and require habitats to achieve good ecological status.

The Working Group further noted that some countries, for example UK (England and Wales), are taking action to define standards (e.g. good practice guides) that must be adopted by developers at each proposed hydropower scheme to ensure appropriate environmental protection. It was also recognized that catchment management strategies are required for multiple schemes within catchments to reduce cumulative impacts on salmon populations. However, it was noted that reaching agreement on such standards was challenging because the requirements identified by fishery interests were commonly seen as major obstacles to the economics of proposed schemes by developers. The Working Group considered that the difficulties posed by current salmon restoration programmes highlighted the importance of establishing robust
standards at the outset and not relying on inadequate mitigation/compensation provisions.

The Working Group also acknowledged the recent marked increase in offshore wind farms. Wind turbines are particularly effective in areas where winds are stronger and more constant and, because offshore areas experience mean windspeeds far in excess of that on land, there is particular interest in establishing wind farms in coastal areas. Wind farms and other offshore renewable energy developments can impact on the environment during construction, operation and decommissioning (Gill, 2005). Commonly, construction and decommissioning are likely to cause some physical disturbance (e.g. noise and sediment load) with potential implications for local biological communities, the significance of which will likely depend on the extent of the disturbance and the resilience of the communities (Gill, 2005). However, once operational, underwater noise and the emission of electromagnetic fields from such developments may represent longer term and more serious threats for coastal and migratory species. The likelihood of any such impacts on Atlantic salmon will depend on interactions between the migratory routes of salmon, the behaviour of the fish in the proximity of the development, the location and distribution of proposed offshore developments, and the technologies deployed.

In recognition of the potential impact of wind and tidal offshore developments on migratory species, scientists in UK (Scotland) have recently reviewed the available information on the migratory routes and behaviour of Atlantic salmon (and other diadromous species) in Scotland's coastal environment (Malcolm et al., 2010). The Scottish Government has set targets to generate $80 \%$ of national power capacity from renewable sources by 2020 . However, it is recognized that the development of marine renewables will need to incorporate processes to assess, manage and minimize environmental impacts through appropriate planning and licensing processes for such schemes (Malcolm et al., 2010). This study identified broad scale migration patterns for adult salmon, but recognized these were unlikely to be sufficient to inform sitespecific risk assessments. Information on juvenile migratory routes was even less well developed and absent for important east coast rivers. The report concluded that significant knowledge gaps remain and that these should be considered as part of an overall assessment of research needs in relation to offshore renewable developments and diadromous fish.

Detailed studies on the species composition, distribution and relative abundance of the fish community are needed for any proposed offshore development to understand the effects the proposed action will have on the fish community within the deployment area. Additional behavioural studies are also required on key species in relation to changed hydrokinetics. Within the USA, proposals for tidal energy have increased in recent years. The estimated environmental risks involved with tidal energy depend mainly on design, size, and deployment method. One of the risks involved with tidal energy is the damage associated with physical encounter with the turbines; this raises particular concerns in relation to the rotation speed of the turbine blades. Vertebrates (e.g. fish and seals) could be struck by blades and suffer injury or death (Wilson et al., 2007). For this reason, observations of what animals may be found within the assumed strike range of the turbine blades need to be made. Studies using hydroacoustics and midwater trawlnetting have been initiated in support of a proposed hydrokinetic tidal power project to record the vertical distribution of fish at proposed turbine deployment sites and control sites on seasonal, daily, and tidal time-scales. These data are essential to understanding the ecosystem effects that new alternative/renewable energy projects may have on the fish community.

The Working Group concluded that great care must be taken to minimize the impact of renewable energy schemes on salmon (and other species) through careful development, device design and site selection. The Working Group highlighted that the pressures to expand renewable energy raised additional concerns, particularly given unresolved difficulties in establishing and maintaining appropriate safeguards for aquatic biodiversity in previous hydropower developments, and the risks posed by individual and cumulative developments within a catchment.

### 2.3.3 Overview of best solutions for fish passage with examples of practices in member countries

NASCO asked ICES to provide information on best solutions for fish passage and associated mitigation efforts with examples of practices in member countries.

The Working Group noted that river connectivity was vital in maintaining biodiversity and that maximizing the production of juvenile salmon in freshwater was particularly important at a time when the levels of salmon survival at sea were low. It is thus essential that all potential nursery habitat can be reached by salmon, and that smolts can freely reach the sea. Restricted fish passage can have significant ecological impacts. For example, salmon may be excluded from important nursery habitats, increasing levels of predation (by fish, birds and anglers), or disease/parasite incidence, can occur where salmon aggregate at obstacles and move through impoundments, and smolts and kelts can be injured or killed on spillways, sills or in turbines, as they migrate downstream. The Working Group recognized that in the face of increasing pressures on freshwater ecosystems, for example as a result of the growing threat from small-scale hydropower plants as identified in the previous section, effective fish passage solutions were essential.

The Working Group noted that there are several national and international manuals and comprehensive guides on both upstream (e.g. Evans and Johnston, 1980; Powers et al., 1985; Struthers, 1993; Clay, 1995; Larinier, 2002; FAO/DVWK, 2002; Kroes et al., 2006; Jungwirth et al., 1998; NMFS, 2008; Degerman, 2008; Grande, 2010; Environment Agency, 2010) and downstream fish passage (e.g. Poe et al., 1993, Washington Department of Fish and Wildlife, 2000; Larinier and Travade, 2002; Deutsche Vereinigung für Wasserwirtschaft, 2005; NMFS, 2008).

Fish passage considerations include both upstream and downstream passage. Upstream passage can be achieved in a number of different ways. Removal of the obstacle (often dams) is the best solution. Opening of a dam or sluice gates can be used in some situations, but this is rarely applicable and a simple fish pass may be still required if water velocity or the head of water is too high for fish to swim upstream. Other options are to construct fishways; these can be 'natural' or 'technical'. 'Natural' fish passes include rocky ramps or the creation of channels either within or outside the watercourse. Technical fishways come in many types; these include: (a) pool and weir fishways (traditional fish ladders); (b) vertical slot fishways; and (c) Denil and Larinier fishways (roughened channels). Other, less frequently used options include: fish elevators, fish locks, fish pumps and the trapping and transport of ascending spawners.

The technology available for upstream fish passage is more advanced than that available for downstream passage. There are particular concerns with downstream passage in relation to hydropower generation (Section 2.3.2). The key requirement to achieving effective downstream passage past obstructions is to lead the fish to a spillway or by-pass. Fish tend to go with the flow, which can present a particular
problem when most of the water is led through turbines. Ensuring suitable bypass flows and adequate attraction flows (relative to generating flow) are considered critical variables regulating the effectiveness of downstream fish passage (Rivinoja, 2005).

## Examples of practices in member countries

## River Rhine, Germany

The stocks of Atlantic salmon in the River Rhine were lost at the end of the 1950s, and a reintroduction programme started in 1978 with the aim of re-establishing selfsustaining runs. One of the main obstacles that needs to be addressed is the upstream and downstream passage of fish. There are particular concerns about the movement of fish into and through the Rhine delta, with the Haringvliet Sluice in the Netherlands considered a major obstacle. However, free passage of fish is also a problem in most of the Rhine tributaries, both with regard to fish reaching their spawning grounds and in relation to losses of smolts at hydropower plants.

## River Ätran, Sweden

The River Ätran is the most important salmon river on the Swedish west coast. In 1903 a power plant was established close to the mouth and salmon and sea trout had great difficulties passing this and a previous fish ladder. In 1946, the dam was equipped with a Denil fishway and this immediately improved upstream access for salmon. The salmon population in the River Ätran is currently assessed as of good status; 3000-5000 Atlantic salmon and sea trout have been counted passing the power plant annually over the period 2000 to 2010 . However, upstream migration remains a problem for weaker swimmers such as eel and sea lamprey and further changes to the dam are proposed. Downstream passage of fish in the river has been an ongoing problem.

## River Monnow, UK (England and Wales)

In 2009, a fish pass was installed on Osbaston Weir on the River Monnow, one of the largest tributaries of the River Wye in Wales. The rock ramp by-pass channel opened up 200 km of the river to a wide range of species, and salmon have since been seen spawning upstream of the weir, with juvenile salmon found in subsequent fishery surveys.

## River Taff, UK (England and Wales)

The River Taff is a recovering river in south Wales. Three fish passes have recently been installed $(2003,2005$ and 2009$)$ on the river to help with the re-establishment of salmon. Prior to the installation of the passes, there were no salmon upstream. However, there has been progressive recolonization of the newly accessible areas since this time, with over $70 \%$ of the sites surveyed for juvenile salmon containing salmon fry in 2010.

## River Himleån, Sweden

The River Himleån is a small catchment in Sweden. In the 1980s, salmon were absent from the river due to migration barriers, acidification in the upper parts, eutrophication in the lower parts and canalisation for drainage of agricultural areas. Today, 38 km of the river is accessible to salmon after removal of three dams and other habitat improvement measures. There has been a steady improvement in the densities of
salmon parr in the river and the stock is currently assessed as being above conservation limits, i.e. from a lost salmon population to a healthy river in 23 years.

## Summary

The Working Group noted that there was extensive information available on fish pass design and that improving fish passage had contributed to sustaining and recovering wild salmon populations. In addition, the technology available for upstream fish passage is often more advanced than that available for downstream passage. However, scientific evaluation was often absent or inadequate. It was recognized that fishways are never $100 \%$ effective, so a proportion of the migrating population is typically lost at each such structure. In rivers with multiple passes/barriers this can have substantial negative cumulative effects resulting in few spawners reaching the nursery areas and/or few smolts reaching the sea.

The Working Group recognized that careful design, adequate water supply and proper maintenance were crucial to well functioning fishways. Where this was possible, the removal of dams had provided some positive examples of restoration, and complete removal of obstructions offered the best solutions for upstream and downstream movements of aquatic species without delays or mortality. However, there were many more examples of poorly designed and inefficient technical fishways where problems persisted with insufficient studies on the effectiveness of such structures.

### 2.3.4 Recent results from acoustic tracking investigations in Canada

The Working Group reviewed the results of ongoing projects, led by the Atlantic Salmon Federation (ASF) to assess estuarine and marine survival of tagged Atlantic salmon released in rivers of the Gulf of St Lawrence.

In all 249 smolts and 52 kelts were sonically tagged in four rivers between April and June 2010. The proportion of smolts detected (apparent survival) in 2010 from freshwater release points to the head of tide, and from the head of tide to estuary exits, were similar for each of the rivers to those that have been observed in previous years (Figure 2.3.4.1). By contrast, there was an improvement in the proportion of fish detected across the Gulf of St Lawrence to the Strait of Belle Isle (Figure 2.3.4.1). This was especially true of the Cascapedia River, where most few of the fish that successfully exited from the Baie des Chaleurs into the Gulf of St Lawrence were later be detected in the Strait of Belle Isle.

For the first time in four years of study, a smolt from the St Jean River (Quebec North Shore) was detected crossing the Strait of Belle Isle in 2010. This fish passed through the Strait in the same time frame as fish from the Miramichi, Restigouche and Cascapedia Rivers.

Although kelts arrived at the Strait of Belle Isle slightly in advance of smolts, there was an overlap of smolt and kelt movements past the array. Synchronized movements past the array was more pronounced for smolts from the four river systems (Figure 2.3.4.1).

There was a partial detector array functioning in the Cabot Strait ( 37 km northward from Cape Breton Island) exit of the Gulf of St Lawrence in 2010, but no tagged smolts were detected. A kelt from the St Jean River (Quebec North Shore) that had been tagged migrating upstream in 2009 and left the river in spring 2010 was detected
at this array. One of two kelts tagged leaving the Margaree River in 2010 also crossed the Cabot Strait, the other was recorded at the Strait of Belle Isle array.

Six satellite-linked passive drifters were released in 2010 to determine surface water currents in the Gulf of St Lawrence at the time of the smolt migration. The rate of movement of these drifters was slow and half or less of the calculated speeds of the migrating smolt. The timing and direction of the prevailing surface currents did not match the directions taken by the smolt from these areas.

### 2.3.5 Assessing the impact of common assessment procedures on smolt physiology, behaviour and adult return rates

Marine survival estimates for various Atlantic salmon stocks are reported annually to ICES as part of the Working Group's assessment activities. It has previously been noted, however, that the assessment methodologies used in deriving these estimates may have a negative effect on fish behaviour and survival (Hansen, 1988; Hansen and Jonsson, 1988; Moffett et al., 1997; Crozier and Kennedy, 2002; Riley et al., 2007). Indeed, Crozier and Kennedy (2002) reported that over a 13 -year period wild salmon smolts tagged with Coded Wire Tags (CWT) on the River Bush, Northern Ireland had return rates $56 \%$ lower than untagged fish.

The Working Group noted recent investigations conducted in UK (England and Wales) to assess the impact of trapping, handling, anaesthesia and tagging (CWT) of Atlantic salmon on smolt physiology, smolt migratory behaviour and subsequent adult return rates.

## Physiology of wild migrating smolts-River Frome

Cortisol levels determined from blood plasma of actively migrating smolts caught on the River Frome indicated a highly significant ( $p<0.01$ ) increase in plasma cortisol concentrations following capture, consistent with an acute ('fight or flight') stress response.

## Physiology of hatchery-reared smolts - laboratory study

Hatchery-reared smolts were randomly assigned to one of five experimental treatments ( $n=6$ per treatment): control; handled/ no anaesthetic; anaesthetized/ handled; anaesthetized/ adipose fin clip only; anaesthetized/ adipose fin clip and CWT. Water samples were then drawn from each tank during an initial acclimation period and at regular intervals post-treatment after the fish had been returned to the tank. This continued for four days in freshwater and for a further three days following an in situ transfer to seawater; the water samples were analysed to determine the cortisol release rate.

Cortisol release rates remained at around $4 \mathrm{ng}^{-1} \mathrm{~g}^{-1} \mathrm{~h}^{-1}$ in the control fish throughout the experiment. However, all fish subjected to a handling or tagging procedure responded with an acute stress response with an increase in cortisol release rates for three to twelve hours after the procedure. After this time period, cortisol release rates rapidly returned to baseline levels indicating that there was no chronic stress response in any of the groups.

There were a small number of mortalities after fish were transferred to salt water, although the small sample size makes it difficult to draw robust conclusions about the influence of handling and tagging. Nevertheless, all those fish that died in salt water had undergone a handling or tagging procedure and all released cortisol at a
consistently higher rate throughout the experimental period than those fish that survived. Variation in the cortisol response to stress is an individual trait that has been demonstrated to be stable over time with a degree of heritability. It may be that the fish that died after transfer to salt water exhibited a natural 'high-response' to stress and that this meant they were less able to cope with the additional stressors of handling/tagging as well as the subsequent saltwater transfer.

## Wild smolt migratory behaviour-River Ceiriog

Each September, in the years 2004 to 2006, wild salmon parr were captured, PIT tagged and released back into the River Ceiriog, a tributary of the Welsh Dee in North Wales, at their site of capture. In total, 5709 parr were tagged over the period. A proportion of these tagged salmon were subsequently monitored as they migrated downstream using a PIT tag detection system installed in the water intake of a trout farm. In April and early May 2006 to 2007, a proportion of the PIT-tagged smolts migrating downstream were intercepted using a rotary screw trap (RST), 1.1 km upstream from the water intake. All PIT-tagged smolts caught were anaesthetized and tagged with a CWT, before being returned to the river immediately downstream of the RST. The previously PIT-tagged smolts that migrated past the RST without being caught and that were subsequently detected at the water intake were used as the control group.

In both 2006 and 2007, the downstream migration timing of the control group of smolts was significantly correlated with the time of sunset. However, the downstream migration timing of the smolts intercepted and tagged with CWTs was statistically random with respect to sunset (Riley et al., 2007).

## Adult return rates-River Frome

Each September, in the years 2005 to 2008, around 10000 wild salmon parr have been captured, PIT tagged and released back into the River Frome in Dorset, at their site of capture. In total, about 43000 salmon parr were PIT tagged over the period. During the following springs (2006-2009), 1779 PIT tagged salmon smolts were intercepted, using a RST in the lower reaches of the Frome. All PIT-tagged smolts caught were anaesthetized, tagged with a CWT, and returned to the river immediately downstream of the RST within 45 minutes of capture. The 3295 PIT-tagged smolts that successfully migrated past the RST during spring without being caught, but that were detected using PIT antenna systems deployed in the lower Frome, were used as the control group. Differences in the survival between the CWT tagged fish and the control population were determined based on the adult return detection rate of the two groups recorded by a cross-river PIT antenna array (Ibbotson et al., 2004) located 4.1 km upstream of the tidal influence.

Adult return rates have varied year on year. In two years, there was no difference between the return rates of the control and tagged groups, while in the other two years the return rate of the tagged group was lower. To date (November 2010), there has been a $34.5 \%$ reduction ( $p<0.05$ ) in returns from RST intercepted/ CWT smolts compared with the control group. However, the results are strongly influenced by the returns of one smolt cohort (2007) and data are required from more years. The smolt run in 2007 was atypical, with $>72 \%$ of the smolts caught and released during the daylight, possibly making them more vulnerable to visual predators, although environmental variation and run timing are also likely to play a key role in smolt survival. The River Frome study is planned to continue until 2014 and based on current
adult salmon return rates it is anticipated that this will enable a more robust assessment of the effects of handling/tagging on adult return rates.

## Summary

Ongoing concerns about trends in the marine mortality of salmon, together with reliance on marine survival data as inputs for stock assessment and modelling, emphasize the vital importance of obtaining accurate marine survival data. The results of this and earlier studies suggest that the additional mortality associated with the handling and tagging of wild smolts should be taken into account when assessing marine survival. However, further work is needed to assess the extent to which such handling and tagging effects might vary year on year in response to factors such as environmental effects and smolt run timing.

### 2.3.6 Red vent syndrome

Over recent years, there have been reports from a number of countries in the NEAC and NAC areas of salmon returning to rivers with swollen and/or bleeding vents. The condition, known as red vent syndrome (RVS), has been noted since 2005, and has been linked to the presence of a nematode worm, Anisakis simplex (Beck et al., 2008). This is a common parasite of marine fish and is also found in migratory species. The larval nematode stages in fish are usually found spirally coiled on the mesenteries, internal organs and less frequently in the somatic muscle of host fish. However, their presence in the muscle and connective tissue surrounding the vents of Atlantic salmon is unusual. The reason for their occurrence in the vents of migrating wild salmon, and whether this might be linked to possible environmental factors, or changes in the numbers of prey species (intermediate hosts) or marine mammals (final hosts) remains unclear.

A number of regions within the NEAC stock complex observed a notable increase in the incidence of salmon with RVS during 2007 (ICES 2008a), but levels have been lower in some NEAC countries since 2008 (ICES 2009a; ICES 2010b). However, levels of RVS on monitored rivers in UK (England and Wales) and in France have typically remained high ( $20-60 \%$ ) and have changed relatively little over recent years. During a fishery survey by Inland Fisheries Ireland in summer 2010, a sample of 392 salmon was examined for the prevalence of Anisakis symptoms. Of these $6 \%$ demonstrated no symptoms, $20 \%$ revealed slight reddening of the vent/ no swelling, $33 \%$ displayed severe reddening / no swelling, $25 \%$ displayed severe reddening /slight swelling, while $15 \%$ demonstrated severe reddening /severe swelling. The presence of Anisakis was confirmed in a number of samples, while others have been sent for a full parasitological examination. Trapping records for rivers in UK (England and Wales) for the last six years indicate that RVS has generally been less prevalent in early and late running fish than mid-season fish. Early running fish comprise mainly MSW salmon whereas late running fish are predominantly 1SW fish. Within the NAC stock complex, RVS has previously been detected in the Scotia-Fundy (2008 and 2009) and Quebec regions.

There is no clear indication that RVS affects either the survival of the fish or their spawning success. Affected fish have been taken for use as broodstock in a number of countries, successfully stripped of their eggs, and these have developed normally in hatcheries. Recent results have also demonstrated that affected vents demonstrated signs of progressive healing in freshwater, suggesting that the time when a fish is ex-
amined for RVS, relative to its period of in-river residence, is likely to influence perceptions about the prevalence of the condition.

### 2.3.7 Reduced sensitivity and development of resistance towards treatment in the salmon louse (Lepeophtheirus salmonis)

In the two previous reports, the Working Group highlighted concerns arising from Norway regarding the development of reduced sensitivity of the salmon louse (Lepeophtheirus salmonis) to oral treatment (ICES 2009a; ICES 2010b). Though both the aquaculture industry and management authorities are taking actions, this problem still remains a potential threat to wild salmon populations. The monthly reports of lice numbers on aquaculture salmon, reported by fish farmers, demonstrate that the average number of adult lice on salmon in January and February 2011 for Norway as a whole, was at the same high level as seen in the previous year (www.lusedata.no). Throughout 2010, levels were on average higher than the previous year in the periods January to March and August to November. Coordinated delousing efforts carried out in early spring managed to reduce lice numbers over the period of the smolt migration to approximately the same levels recorded in the two previous years (Anon., 2010a). The relatively low infestation levels on farmed salmon achieved in the main smolt migration period may have allowed most wild smolts to complete their migration from rivers to the open ocean without heavy lice infestation. However, smolts migrating later from cold rivers in the fjords may not have had time to reach the coast before lice levels started increasing at the beginning of June (Anon., 2010).

Investigations of lice infestation rates on wild salmonids (salmon and trout) also indicate that lice infestation was low in May, and increased from the beginning of June. In some areas, infestation levels on sea trout reached very high levels during summer, and sea trout populations in these areas are severely affected (Bjørn et al., 2010).

Due to the reduced sensitivity, and in some cases resistance, to the commonly used oral treatment against salmon lice, alternative chemicals and treatment methods have been applied in several areas. Resistance towards treatment continues to be a growing problem in some regions, giving cause for concern for future years.

### 2.3.8 Atlantic salmon genetics-new initiatives in relation to management of mixed-stock coastal fisheries in northern Norway

SALSEA-Merge and other current and previous projects have contributed to the establishment of a comprehensive genetic baseline for salmon populations in northern Europe. Work continues to further develop this baseline for the salmon populations of northernmost Europe into a practical and useful tool for management of mixedstock coastal fisheries in Norway and Russia. Last year, the Working Group reported (ICES 2010b) on a pilot project that expanded the baseline for a number of Russian rivers, and ongoing genetic analysis and assignment of samples from salmon caught in coastal fisheries in Norway. Power analysis of the genetic baseline developed indicate that with the present coverage, and number of genetic markers used, around 50\% of the samples from coastal fisheries can be reliably (probability $>90 \%$ ) assigned to river. However, it was recognized that the spatial coverage of the baseline should be expanded, and additional sampling should be conducted in a number of rivers to improve the precision of the assignment of individuals.

A further initiative to achieve this has been taken by Norway, Russia and Finland. In 2011 a new EU project "Trilateral cooperation on our common resource; the Atlantic salmon in the Barents region" (Kolarctic Salmon) was started. The project funding
consists of both EU-funding (Kolarctic ENPI CBC) and national funding from Norway, Russian Federation and Finland.

Through the activities outlined in the project plan, a model for coastal migration of returning spawners to these northern salmon rivers will be developed. Up to 100 northern rivers will be added to the genetic baseline, and up to 18000 samples from coastal fisheries in Norway and Russia will be analysed. Through the activities in this project, a foundation will be established on which a river-specific management regime for coastal and riverine fisheries for these northern populations can be implemented.

### 2.3.9 SALSEA West Greenland

The marine survey aspect of the SALSEA program was developed to concentrate marine sampling upon areas where stocks from many rivers co-occur, because declines in marine survival are affecting stocks over broad geographic areas. Considering that both southern European and North American stocks co-occur at West Greenland as 1SW fish, an additional land-based survey was developed for West Greenland (SALSEA West Greenland). SALSEA West Greenland is designed to enhance the current Baseline Sampling Program (Section 5.1.2) and integrate it with the previous coordinated marine surveys in other oceanic areas (SALSEA North America and SALSEAMerge). Collectively, these data and data from subsequent in-river sampling programmes in home waters will be used to investigate hypotheses on the causal mechanisms driving stock-specific performance in the ocean (i.e. marine survival).

As in 2009, the 2010 Baseline Sampling Program was delivered by seven samplers from Canada, Greenland, UK (England and Wales), UK (Scotland), and USA (2) stationed in three different communities representing three different NAFO Divisions during 11 of the 14 weeks of the fishery. The SALSEA West Greenland Enhanced Sampling Program was successfully integrated into this program and a total of 358 fresh whole salmon were purchased directly from individual fishermen for detailed sampling. Fresh whole fish are needed, as the protocols for many of the samples require the collection of fresh internal tissues. The following is a list of the samples collected in 2010 and their purpose:

- adipose tissue samples preserved in RNALater for origin determination;
- scales samples for age and growth studies;
- stomach samples preserved in formalin for diet studies;
- sea lice collections preserved in both RNALater and EtOH for Slice ${ }^{\circledR}$ resistance and population genetics studies;
- muscle fillet sections frozen for lipid analysis;
- otolith and water samples for oxygen isotope analysis;
- heart and kidney samples preserved in both RNALater and formalin for parasite (Ichthyophonus) investigations;
- pyloric caeca, gill arch, liver, spleen, kidney, and heart samples preserved in formalin for miscellaneous parasite investigations;
- intestines preserved in formalin for parasite analysis;
- kidney samples preserved in RNALater and frozen for ISAv analysis;
- adipose and caudal fin clip, dorsal muscle and liver frozen samples and scale samples for stable isotopes analysis;
- gillrakers, pyloric caeca, spleen, and kidney frozen samples for miscellaneous disease investigations.

All carcasses, post sampling, were returned to the communities where the sampling took place. Sample auditing and processing are currently underway. The Working Group recommends that SALSEA West Greenland be conducted in 2011 for a third year and that efforts continue to integrate the results from this sampling programme with results obtained from both SALSEA-Merge and SALSEA North America.

### 2.3.10 Salmon bycatch in the Icelandic mackerel fishery

Only limited information exists on the distribution of salmon in Icelandic waters as ocean fisheries for salmon have been banned for more than 70 years. In 2010, the Icelandic Directorate of Fisheries launched a programme to investigate the incidence of salmon bycatch in a new mackerel fishery, which started in late May of that year. The programme was limited to 1000-3000 tonne multi-gear vessels, which fished with a midwater trawl and landed their catch in processing factories and freezing plants all over Iceland. The monitoring of these landings for salmon bycatch was primarily carried out in land-based sorting facilities prior to processing and freezing of the mackerel catch. The sampling rate was 40 kg per 100 t of landed catch. However, a few salmon were also recovered in factory trawlers. For each salmon, information was recorded on the date and place (coordinates) of capture, along with the length, weight and sex of the fish and details of any tags recovered. The salmon's head was also retained.

Most of the bycatch of salmon occurred in areas off eastern and northeastern Iceland during the early summer. The total bycatch recorded during the 2010 sampling was 170 adult salmon, most of which were 1SW fish less than 60 cm in fork length. No post-smolts were detected. Four of the salmon were tagged, three with CWTs and one with a Carlin tag. Three of the tags originated in Norway and one from Ireland.

The Working Group welcomed this opportunistic assessment of the incidence of salmon bycatch in this pelagic fishery and also the opportunity to collect samples from the salmon caught, as this provided new information on the temporal and spatial distribution of salmon in this area, as well as the biology of the fish. It was recognized that systematic screening and sampling of the bycatch needed to be done by skilled personnel in order to provide reliable information. Further work is planned to utilize the sampled fish, including DNA analysis against the genetic baseline developed as part of the SALSEA programme. This might provide further opportunities to trace the salmon back to country of origin or even to specific areas or rivers. The results of this sampling will be reported as a part of the SALSEA project; further sampling is planned for the 2011 mackerel fishery season.

### 2.3.11 Reintroduction of salmon-developments on the River Rhine

The programme of reintroducing Atlantic salmon to the River Rhine started 20 years ago. It is part of a wider ecological rehabilitation programme involving all countries bordering the river and coordinated by the International Commission for the Protection of the River Rhine (ICPR). This was initiated in response to catastrophic river pollution in Switzerland in 1986 which killed hundreds of thousands of fish. The programme aims to bring about significant ecological improvement of the Rhine and its tributaries enabling the re-establishment of migratory fish species such as salmon.

Stocking of juvenile salmon started in 1988 and the first adult salmon was recorded in the River Sieg, a tributary of the Rhine, in 1990, more than 30 years after the extirpation of salmon from the Rhine catchment. Naturally produced juvenile salmon were first observed in 1994 and since the start of the programme more than 6200 adult salmon, mainly from stocking, have been recorded in the Rhine and its tributaries. The actual number of returned salmon is probably somewhat higher than 6200, because some tributaries are not equipped with detection facilities and in other rivers salmon can also by-pass these facilities. In some tributaries, for example the River Moselle and River Wupper, further monitoring stations are planned. Stocking of juveniles is planned to continue in the coming years with more than one million individuals released each year. Access to suitable juvenile salmon habitat in the upper part of the Rhine and most of its tributaries is still restricted by dams and weirs, and smolts migrating downstream have to pass hydropower plants. However, future improvements in both fish passage and water quality are expected as a result of the implementation of the Water Framework Directive, and this should facilitate the restoration of the salmon population in the River Rhine.

After a successful pilot project in 2006, the downstream migration of Atlantic salmon smolts has been monitored in the River Rhine since 2007 using the NEDAP Trail system (Breukelaar et al., 1998). The study aims to investigate the success of downstream migration through Germany and the Netherlands and to assess the migration routes in relation to the obstructions within the partly dammed Rhine Delta, particularly the Haringvliet sluices. Tagged smolts have been released each year since 2007 in two tributaries of the River Rhine about 330 km from the sea. The smolts (hatchery $2^{+}$, weight $>150 \mathrm{~g}$ ) have been tagged with transponders (length 3.5 cm , weight 11.5 g ) by implantation into the body cavity, and allowed to recover for ten days in the hatchery before release to the river. Within that period no post tagging mortality has been observed. The tagged fish were subsequently detected by fixed antenna arrays when leaving the tributary and during their migration through the Rhine Delta to the sea using the NEDAP trail system (ICES 2008a, 2009a, 2010b).

The number of fish reaching the sea after passage through the delta has typically been relatively low; the highest percentage ( $46 \%$ ) occurred in 2007 and may reflect higher discharge in that year. The study was repeated in 2010 and results suggest a slight preference for night-time migration ( $52 \%$ of all detections) in common with 2009 (Spierts et al., 2009), but in contrast to investigations in 2007 and 2008 when the smolts had a slight preference for daytime migration (Vriese and Breukelaar, 2007; Spierts et al., 2008). In 2010, the fastest smolts entered the sea after ten days, for smolts released in River Wupper and River Dhünn, and after 19 days for smolts released in the River Sieg. In common with previous years, the most important migration route from all rivers to the sea was the passage through the Haringvliet sluices in the Netherlands. The study is planned to continue in 2011 and is aimed specifically at improving conditions for migratory fish species during their passage from freshwater to the sea and vice versa.

The Working Group noted that proposed changes to the way in which the Haringvliet sluices will be operated had potential implications for the success of the programme. Previously, in 2004, the Dutch government had agreed to the implementation of progressive measures to partially open the sluices. Aside from establishing a brackish water biotope, decreasing sludge deposition and improving water quality, this was expected to facilitate the passage of migratory fish species. However, following a change in the Dutch government in 2010 these measures were dropped and ecologically meaningful alternatives are to be examined. This has raised
serious concerns among the different organizations involved in the migratory fish programmes on the River Rhine, because this will affect the main migration route for these fish.

### 2.4 NASCO has asked ICES to report on significant advances in our understanding of associations between changes in biological characteristics of all life stages of Atlantic salmon and ecosystem changes with a view to better understanding the dynamics of salmon populations

The Working Group had considered a preliminary report from the second meeting of the Study Group on the Identification of Biological Characteristics for Use as Predictors of Salmon Abundance [SGBICEPS] at its last meeting (ICES 2010b) and noted that the final study group report had since been published (ICES 2010c). No other new information was presented to the Working Group at the 2011 meeting.

### 2.5 NASCO has asked ICES to further develop approaches to forecast prefishery abundance for North American and European stocks with measures of uncertainty

The Study Group on Salmon Stock Assessment and Forecasting (SGSAFE) was established to further develop Atlantic salmon stock assessment and forecast models and to assist the Working Group in their tasks to provide catch advice to NASCO for management of the North Atlantic high seas salmon fisheries. There were four terms of reference for the study group:
a ) Update and further develop stock and/or catch forecast models for salmon stocks in the NASCO North American (NAC) and Northeast Atlantic Commission (NEAC) areas;
b ) Evaluate options for developing forecast models which include all sea age classes;
c ) Evaluate methods for incorporating uncertainty in the assessments;
d ) Develop risk analyses for the provision of salmon catch advice.
The first meeting of the study group in March 24-26, 2009 was attended by nine participants from Europe and North America. During this first meeting, new forecast models for the NAC and for the NEAC areas were developed and presented at the ICES Working Group meeting in 2009 (ICES 2009a). For the NAC, the input data used in the run-reconstruction were updated, and some of the regional spawner and return inputs were revised. A regional disaggregated model for the single 1SW nonmaturing component was developed using a first order random walk production parameter. The inference portion of the model included uncertainties in the lagged spawner values (as priors) and in the 2SW returns to regions as pseudo-observations. Uncertainties in catches and biological characteristics of the West Greenland fishery were included in the forecast and the full risk analysis for West Greenland was provided. The inference and forecast portions of the model were run in a Bayesian hierarchical framework. Details of the work completed during the first study group are provided in the previous Working Group report (ICES 2009a).

For the NEAC area, efforts were made to translate the run reconstruction of returns and spawners from Oracle CrystalBall® to $R$ software ( $R$ Development Core Team 2007) to facilitate the development of the assessment and forecast model in a Bayesian
hierarchical framework. Models for the southern NEAC and northern NEAC stock complexes, which combined maturing and non-maturing 1SW return streams from common lagged eggs, were developed. The forecast portion of the model was developed for the stock complex level and included a risk assessment of the probability of meeting or exceeding stock complex conservation limits in the absence of any fisheries. The models for NEAC were presented in 2009 and were accepted and used in 2009 and 2010 for the provision of catch advice (ICES (2009a; ICES 2010b). Details of the NEAC model are presented in ICES (2009a). The work of the study group was incomplete in 2009 and the group agreed to continue working on the model development in subsequent years.

Further to the work reported by the Working Group in 2009, the ACOM review of the Working Group report was critical of some aspects of the models and, as a result, an additional term of reference was given to the study group:
e) Explore the possibility of incorporating physical and biological variables into the models that may explain variation in salmon survival.

The second meeting of the study group was held on March 1-4, 2011 in Moncton (NB), Canada. There were thirteen participants, six from Europe and seven from Canada. As in the first study group, experts in Bayesian modelling and Atlantic salmon assessments from France, who were not Working Group members, participated.

Progress of the study group relative to the terms of reference are described.
a ) Update and further develop stock and/or catch forecast models for salmon stocks in the NASCO North American and Northeast Atlantic Commission areas.

The model for NAC originally developed during the first study group meeting of 2009 was refined to account for covariance in the productivity parameters among the regions. Pre-Fishery Abundance (PFA) of 1SW non-maturing salmon is modelled for each region proportionally to lagged spawners using a first order autocorrelated function. The inter-regional variance in the productivity parameter was modelled as a multinormal distribution which ascribes correlation in productivity between regions among years. The justification for using the inter-region covariance matrix for the productivity parameter is that the fish share a common marine environment during part of their life cycle but there can be regional specificities in the evolution of the freshwater and or the marine coastal environment and subsequent variation in productivities.

There were unresolved issues with the NEAC model developed in 2009 which were resolved in the 2011 meeting. These included: the incorporation of the uncertainty in the regional returns for the Bayesian formulation which had not been completed during the previous meeting, an interest in exploring further alternate productivity functions such as the shifting level dynamic, consideration for the disaggregation of the returns and spawners at a sub-complex scale and the development of the full catch advice framework.

The revised NEAC model developed by the study group is a combined sea age-group model with uncertainty in the returns and lagged eggs structured in a hierarchical Bayesian framework. The differences from the 2009 model structure include: a single productivity parameter is estimated for the lagged eggs to PFA association and the proportion maturing is uncoupled from the productivity parameter estimation. The
productivity parameter remains a first order autocorrelated function and in addition the proportion maturing is modelled as a first order autocorrelated function. The revised model is discussed further in Section 3.6 and is applied to develop catch advice for the NEAC south and NEAC north stock complexes.
b ) Evaluate options for developing forecast models which include all sea age classes.

The combined sea age class models have been developed for the NEAC stocks but not for the NAC stock. At present, the spawning-stock variable for NEAC is lagged eggs from both sea age groups and both maturing and non-maturing recruitments are modelled simultaneously with a common productivity parameter. For NAC, only 2SW spawners are used and the Working Group has only considered the recruitment of the non-maturing 1 SW salmon which is the sea age group exploited at West Greenland; the maturing 1SW salmon are not exploited in that fishery.

Some points of discussion were raised regarding the assumptions on heritability of age-at-maturity in the two differing assumptions for NAC and NEAC. For the NEAC model, the assumption is that an egg is an egg regardless of its sea age origin. However, there is an interest in conserving the sea age structure of the spawning-stock which is why the conservation limits are defined by sea age group. A preliminary examination of this assumption could be done by comparing the variation in the proportion maturing parameter with the corresponding proportions of the lagged eggs contributed by one of the sea age groups of the spawners. For the NAC model, the assumption is that there is perfect heritability in that 2 SW salmon spawners are the only contributor to 1 SW non-maturing salmon and that no other sea age groups (including 1SW, 3SW and repeat spawning MSW salmon) produce recruitment of 1SW non-maturing salmon. The study group did not have time to consider a combined sea age-group model for NAC but the model structure similar to that developed for NEAC could be considered.
c) Evaluate methods for incorporating uncertainty in the assessments.

From the very first study group meeting, the development of inference and forecast models in a hierarchical Bayesian framework was considered the most appropriate approach to use. Both the NAC and NEAC models incorporate the uncertainty in the input data (or pseudo-observations) to the models. Further developments which would consider physical or biological variables to characterize the functional relationship between spawners and recruitment must also consider how to incorporate the uncertainty in those variables and in the forecasts.
d) Develop risk analyses for the provision of salmon catch advice.

The development of the catch advice in a risk analysis framework within the Bayesian structure is complete for the NAC model. A similar approach for NEAC was proposed by the Working Group in 2010, further developed at the study group and is being completed by the Working Group (see Section 3.10).
e ) Explore the possibility of incorporating physical and biological variables into the models that may explain variation in salmon survival.

A very good scientific literature review of biotic and abiotic factors associated with biological characteristics and survival of Atlantic salmon is available in the SGBICEPS report (ICES 2010c). The factors vary between NAC and NEAC and even within areas of NEAC. Progress on this term of reference would require the development of models at scales below the stock complex level. No specific work (exploration of forecast
models and environmental variables) on this term of reference was done during the study group.

## Next steps

The study group report is to be finalized by July 2011. The models developed by the study group have been presented to the Working Group and are being used to develop catch advice for both NAC and NEAC. The study group tasks are considered complete and no further meetings are planned. Further work on the question of incorporating environmental variables in assessment and forecast models is expected by collaborators in a new EU funded project, Effective Use of Ecosystem and Biological Knowledge in Fisheries (ECOKNOWS), and one of their deliverables is reporting to ICES.

### 2.6 NASCO has asked ICES to provide a review of examples of successes and failures in wild salmon restoration and rehabilitation and develop a classification of activities which could be recommended under various conditions or threats to the persistence of populations

The Working Group noted that a study group had been established by ICES to address this question. The Study Group on Effectiveness of Recovery Actions for Atlantic Salmon [SGERAAS] was set up and had intended to work by correspondence to make progress on this issue. The Study Group has not been able to address this question and there was no progress to report. The Working Group recognized that the issue of the restoration and rehabilitation of salmon stocks remained a concern, but that the issue could not be appropriately addressed by the Working Group during its annual meeting. The Working Group remains of the view that a study group is the best way to provide this review.

### 2.7 NASCO has asked ICES to provide a compilation of tag releases by country in 2010 and advise on the utility of maintaining this compilation

### 2.7.1 Compilation of tag releases and fin clip data by ICES Member Countries in 2010

Data on releases of tagged, finclipped and otherwise marked salmon in 2010 were provided to the Working Group and are compiled as a separate report (ICES, 2011). In summary (Table 2.7.1.1), about 4.89 million salmon were marked in 2010, an increase from the 3.45 million fish marked in 2009 (ICES, 2010a). The adipose clip was the most commonly used primary mark ( 4.1 million), with coded wire microtags ( 0.52 million) the next most common primary mark and 253073 fish were marked with external tags. Most marks were applied to hatchery-origin juveniles ( 4.6 million), while 269325 wild juveniles and 21147 adults were also marked. The use of PIT (Passive Integrated Transponder) and other implanted tags for marking Atlantic salmon has increased in recent years and these are listed in a separate column in Table 2.7.1.1. In 2010, 14423 PIT tags, Data Storage Tags (DSTs), radio and/or sonic transmitting tags (pingers) were also used.

From 2003, the Working Group has recorded information on marks being applied to farmed salmon. These may help trace the origin of farmed salmon captured in the wild in the case of escape events. At this time, two jurisdictions (USA and Iceland) require that some or all of the sea cage farmed fish reared in their area be marked. In

USA, the broodstock have been screened with molecular genetic techniques, which makes it feasible to trace an escaped farmed salmon back to its hatchery of origin through analysis of its DNA. In Iceland, CWTs are being applied to about $10 \%$ of sea cage farm production. As in previous years, the CWT tagged farmed fish are included in the compilation.

### 2.7.2 Utility of maintaining the tag compilation

In addition to providing a compilation of tag releases by country in 2010, NASCO asked ICES for advice on the utility of maintaining this compilation. The initial idea for the tag compilation database was to simplify detection and return of tag recoveries and information from ocean and offshore fisheries where salmon stocks from many countries could be harvested. Valuable information have been collected from historical tagging datasets on the spatial and temporal distribution of salmon at sea as recently reported by ICES Workshops: WKDHUSTI, WKSHINI and WKLUSTRE (ICES 2007a; ICES 2008b; ICES 2009b).

Following the closure or reduction of most of the oceanic mixed-stock fisheries, there is a reduced need for this multi-country tag compilation. However, in 2010 close to 4.9 million fish were either marked or tagged, of which around 280000 were of wild origin. Tagged salmon are still recovered in different fisheries, including from research vessel surveys and in bycatch screening programmes for salmon. Further, various fishery boards, private companies, and official institutions carry out salmon tagging programmes. In many countries, compilation of a national database is linked to the preparation of the ICES annual tag compilation. Without the deadline set by the annual meeting, the Working Group considered that continuation of national tagging records was likely to be compromised.

In summary, the Working Group still sees value in maintaining the tag compilation, while such large numbers of salmon are being tagged annually and while the return of tags can add to the knowledge of salmon at sea. With the preparation and assistance from the ICES Secretariat the tag compilation can be completed during the annual meeting of the Working Group. The Working Group therefore recommends continuing with the annual compilation of salmon tags and encourages further use of the scientific information gathered from tagging programmes.

Table 2.1.1.1. Reported total nominal catch of salmon by country (in tonnes round fresh weight), 1960-2010. (2010 figures include provisional data).

Kеу:

1. Includes estimates of some local sales, and, prior to 1984 , by-catch.
2. Before 1966 , sea trout and sea charr included ( $5 \%$ of total).
3. Figures from 1991 to 2000 do not include catches taken
in the recreational (rod) fishery.
4 From 1990, catch includes fish ranched for both commercial and angling purposes.
4. Improved reporting of rod catches in 1994 and data derived from carcase tagging and log books from 2002.
5. Catch on River Foyle allocated $50 \%$ Ireland and $50 \% \mathrm{~N}$. Ireland.
6. Angling catch (derived from carcase tagging and log books) first included in 2002.
7. Data for France include some unreported catches.
8. Weights estimated from mean weight of fish caught in Asturias ( $80-90 \%$ of Spanish catch)
9. Between 1991 \& 1999, there was only a research fishery at Faroes. In 1997 \& 1999 no fishery took place;
the commercial fishery resumed in 2000 , but has not operated since 2001.
10. Includes catches made in the West Greenland area by Norway, Faroes,

Sweden and Denmark in 1965-1975.
12. Includes catches in Norwegian Sea by vessels from Denmark, Sweden, Germany, Norway and Finland.
13. No unreported catch estimate for Canada in 2007 and 2008 and incomplete reports for 2009 and 2010. No unreported catch estimates for Russia since 2008.
14. Estimates refer to season ending in given yea

Table 2.1.1.2. Reported total nominal catch of salmon in homewaters by country (in tonnes round fresh weight), 1960-2010. (2010 figures include provisional data). $\mathrm{S}=\mathrm{Salmon}$ ( $2 S W$ or MSW fish). $G=$ Grilse (1SW fish). $\mathrm{Sm}=$ small. $\mathrm{Lg}=$ large; $\mathrm{T}=\mathrm{S}+\mathrm{G}$ or $\mathrm{Lg}+\mathrm{Sm}$.

Key: $\quad{ }^{1}$ No data were provided by the authorities for 2009 and data for 2010 were incomplete, however catch-and-release is understood to have remained at similar high levels.
${ }^{2}$ Data for 2006-2009 is for the DCAL area only; the figure for 2010 is a total for N.Ireland.
${ }^{3}$ The statistics were collected on a voluntary basis, the numbers reported must be viewed as a minimum.

### 3.1 Status of stocks/exploitation

The current status of stocks is considered with respect to the following guidance from ICES.

The conservation limits (CLs) have been defined by ICES as the level of stock that will achieve long-term average maximum sustainable yield (MSY). NASCO has adopted this definition of CLs (NASCO, 1998). The CL is a limit reference point; having populations fall below these limits should be avoided with high probability. Homewater stocks in the NEAC area have been interpreted to be at full reproductive capacity only if the lower bound of the $95 \%$ confidence interval of the most recent spawner estimate is above the CL. In a similar manner, the status of stocks prior to the commencement of distant water fisheries has been interpreted to be at full reproductive capacity only if the lower bound of the $95 \%$ confidence interval of the most recent pre fishery abundance (PFA) estimate is above the Spawner Escapement Reserve (SER).

National outputs of the NEAC PFA model are currently combined in the following groups to provide NASCO with catch advice or alternative management advice for the distant water fisheries at West Greenland and Faroes.

| Southern NEAC countries: | Northern NEAC countries: |
| :--- | :--- |
| Ireland | Finland |
| France | Norway |
| UK (England \& Wales) | Russia |
| UK (Northern Ireland) | Sweden |
| UK (Scotland) | Iceland (north/east regions)1 |
| Iceland (south/west regions) ${ }^{1}$ |  |

Justification for these groupings is provided in Section 3.5.1.
The status of these stock complexes, based on the NEAC run reconstruction model 1971 to 2010, prior to the commencement of distant water fisheries with respect to the SER requirements is:

- Northern NEAC 1SW stock complex is considered to be at full reproductive capacity.
- Northern NEAC MSW stock complex is considered to be at full reproductive capacity.
- Southern NEAC 1SW stock complex is considered to be at full reproductive capacity.
- Southern NEAC MSW stock complex is considered to be at full reproductive capacity.

The status of stocks is shown in Figure 3.1.1.

[^2]Estimated exploitation rates have generally been decreasing over the time period for both 1SW and MSW stocks in Northern and Southern NEAC areas (Figures 3.8.14.1 and 3.8.14.2). Exploitation on Northern 1SW stocks is higher than on Southern 1SW and considerably higher for MSW stocks. The current estimates for both stock complexes are among the lowest in the time-series.

### 3.2 Management objectives

Management objectives are outlined in Section 1.4.

### 3.3 Reference points

Section 1.5 describes the derivation of reference points for these stocks and stock complexes.

### 3.3.1 Description of the national conservation limits model

River-specific CLs have been developed for salmon stocks in some countries in the NEAC area. An interim approach has been developed for estimating national CLs for countries that cannot provide one based upon river-specific estimates. This approach is based on establishing pseudo-stock-recruitment relationships for national salmon stocks in the NEAC area (Potter et al., 2004).

As described in 2002 (ICES 2002), the model provides a means for relating estimates of the numbers of recruits and spawners derived from the PFA model. This is achieved by converting the numbers of 1SW and MSW spawners into numbers of eggs deposited, using the proportion of female fish in each age class and the average number of eggs produced per female. The egg deposition in year ' $n$ ' is assumed to contribute to the recruitment in years " $n+3$ " to " $n+8$ " in proportion to the numbers of smolts produced of ages 1 to 6 years. These proportions are then used to estimate the 'lagged egg deposition' contributing to the recruitment of maturing and nonmaturing 1SW fish in the appropriate years. The plots of lagged eggs (stock) against the 1SW adults in the sea (recruits) have been presented as 'pseudo-stockrecruitment' relationships for each homewater country except for countries with river-specific CLs.

ICES currently define the CL for salmon as the stock size that will result in the maximum sustainable yield (MSY) in the long term. However, it is not straightforward to estimate this point on the national stock-recruitment relationships because the replacement line (i.e. the line on which 'stock' equals 'recruits') is not known for the pseudo-stock-recruitment relationships established by the national model. This is because the stock is expressed as eggs, while the recruits are expressed as adult salmon. In 2001 the Working Group adopted a method for setting biological reference points from the national pseudo-stock-recruitment datasets (ICES 2001). This model assumes that there is a critical spawning stock level below which recruitment decreases linearly towards zero, and above which recruitment is constant. The position of the critical stock level is determined by searching for the value that minimizes the residual sum of squares. This point is a proxy for $S_{\text {lim }}$ and is therefore defined as the CL for salmon stocks. This approach was again applied to the 2010 national stockrecruitment relationship assessment for countries where no river-specific CLs have been determined.

### 3.3.2 National conservation limits

The national CL model has been run for all countries (see Section 3.8.11) and the CLs derived in this way are used for countries where the development of river-specific CLs has not been completed. Where river-specific estimates have been derived (i.e. France, Ireland, UK (England and Wales) and Norway) they are used to provide national estimates (Table 3.3.2.1). The Working Group has previously noted that outputs from the national model are only designed to provide a provisional guide to the status of stocks in the NEAC area. The estimated national CLs have been summed for Northern and Southern Europe and are given in Figure 3.1.1 for comparison with the estimated spawning escapement. The CLs have been calculated as:

- Northern NEAC 1SW spawners: 207231
- Northern NEAC MSW spawners: 131456
- Southern NEAC 1SW spawners: 624504
- Southern NEAC MSW spawners: 258720

The CLs have also been used to estimate the SERs (i.e. the CL increased to take account of natural mortality between the recruitment date (1st January) and return to homewaters) for maturing and non-maturing 1SW salmon from the Northern NEAC and Southern NEAC stock complexes. The SERs are shown in Figure 3.1.1 and Table 3.3.2.1. The Working Group also considers the current SER levels may be less appropriate to evaluating the historical status of stocks (e.g. pre-1985), that in many cases have been estimated with less precision.

### 3.3.3 Progress with setting river-specific conservation limits

In Norway, CLs have been developed for 439 rivers since 2007. The CLs are based on stock-recruitment relationships in nine rivers. In 2010 attainment of CLs was evaluated for 211 Norwegian rivers based on data from 1993 to 2009, but advice on exploitation was not given in 2010. Work is now in progress to provide management advice for 211 rivers based on data from 1993-2010.

In Iceland, progress has been made in setting conservation limits for salmon rivers. Information on the production demonstrates a wide range in salmon catch from 2.1 to 57.7 adult fish per ha wetted area. This wide production range reveals that there will be large differences in the spawning requirements among rivers. There are only few rivers with available measurements of wetted area but an effort will be made to increase that number in the coming years. Juvenile surveys will be used to calculate the relationship between spawning and recruitment and rod catch statistics to transfer CL between rivers of similar origin and characteristics. It is, however, noted that this might take a few years (5-10) before being fully adopted. The salmon run and catch has been high in most Icelandic rivers for the past few years and many rivers have demonstrated record high catches. This good situation and the economic recession have slowed the need and progress of setting river based conservation limits for Icelandic salmon rivers although the work continues.

In UK (Northern Ireland) conservation limits have been determined for a number of important salmon rivers in the Department of Culture Arts and Leisure (DCAL) area, through the transport of optimal productivity metrics determined from the River Bush stock recruitment study to measured habitat parameters for the other rivers. Habitat surveys were initiated on the Upper Bann and Moyola rivers in 2010 to facilitate the derivation of CLs for both these catchments. The Loughs Agency has estab-
lished conservation limits and compliance monitoring for the two main rivers (Foyle and Roe) out of the total of five rivers in their jurisdiction.

### 3.4 Management advice

The Working Group considers that the following quantitative catch advice, based upon the PFA forecasts and estimated SERs shown in Figures 3.6.2.4 and 3.6.2.5, is appropriate to management advice at the stock complex level. Management at finer scales should take account of individual river stock status. Based on recent work on resolving the most appropriate stock groupings for management advice for the distant water fisheries (ICES, 2002; 2005) the Working Group agreed that:

- Advice for the Faroes fishery should be based upon all NEAC stocks.
- Advice for the West Greenland fishery should be based upon Southern NEAC non-maturing 1SW salmon stocks.

### 3.4.1 Northern NEAC maturing 1 SW stock

- The Bayesian forecast model shows that the lower bounds of the forecasted PFA for 2011 to 2014 are below SER indicating that the stock is at risk of suffering reduced reproductive capacity prior to the commencement of distant water fisheries (Figure 3.6.2.5).
- In the absence of specific management objectives for this stock complex the precautionary approach is to fish only on maturing 1SW salmon from rivers where stocks have been revealed to be at full reproductive capacity. Furthermore, due to the different status of individual stocks within the stock complex, mixed-stock fisheries present particular threats to stock status.

### 3.4.2 Northern NEAC non-maturing 1 SW stock

- The Bayesian forecast model shows that the medians and lower bounds of the forecasted PFA for 2011 and 2012 are above SER indicating that the stock is at full reproductive capacity prior to the commencement of distant water fisheries. For 2013 and 2014, the lower bounds of the forecasted PFA are below SER indicating that the stock is at risk of suffering reduced reproductive capacity prior to the commencement of distant water fisheries (Figure 3.6.2.5).
- In the absence of specific management objectives for this stock complex the precautionary approach is to fish only on non-maturing 1SW salmon from rivers where stocks have been revealed to be at full reproductive capacity. Furthermore, due to the different status of individual stocks within the stock complex, mixed-stock fisheries present particular threats to stock status.

### 3.4.3 Southern NEAC maturing 1 SW stocks

- The Bayesian forecast model shows that the lower bounds of the forecasted PFA for 2011 to 2014 are below SER indicating that the stock is at risk of suffering reduced reproductive capacity prior to the commencement of distant water fisheries (Figure 3.6.2.4).
- In the absence of specific management objectives for this stock complex the precautionary approach is to fish only on maturing 1SW salmon from riv-
ers where stocks have been revealed to be at full reproductive capacity. Furthermore, due to the different status of individual stocks within the stock complex, mixed-stock fisheries present particular threats to stock status.

### 3.4.4 Southern NEAC non-maturing 1SW stocks

- The Bayesian forecast model shows that the lower bounds of the forecasted PFA for 2010 to 2014 are below SER indicating that the stock is at risk of suffering reduced reproductive capacity prior to the commencement of distant water fisheries (Figure 3.6.2.4). There are no catch options at West Greenland that would allow the management objectives to be met for this stock complex.
- In the absence of specific management objectives for this stock complex, with the exception of the West Greenland fishery, the precautionary approach is to fish only on non-maturing 1SW salmon from rivers where stocks have been revealed to be at full reproductive capacity. Furthermore, due to the different status of individual stocks within the stock complex, mixed-stock fisheries present particular threats to stock status.

### 3.5 Relevant factors to be considered in management

The management of a fishery should ideally be based upon the status of all stocks exploited in the fishery. Fisheries on mixed-stocks pose particular difficulties for management, when they cannot target only stocks that are at full reproductive capacity. Management objectives would be best achieved if fisheries target stocks that have been revealed to be at full reproductive capacity. Fisheries in estuaries and especially rivers are more likely to meet this requirement.

The Working Group also emphasized that the national stock CLs are not appropriate to the management of homewater fisheries. This is because of the relative imprecision of the national CLs which do not take account of differences in the status of different river stocks or sub-river populations, and because of the capacity of homewater fisheries to target specific stocks. Nevertheless, the Working Group agreed that the combined CLs for national stocks exploited by the distant water fisheries could be used to provide general management advice at the level of the stock complexes.

As noted in previous years, the inclusion of farmed fish in the Norwegian catches could result in the stock status being overestimated (Potter and Hansen, 2001).

### 3.5.1 Grouping of national stocks

National stocks are combined into Southern NEAC and Northern NEAC groups (see Section 3.1) to provide NASCO with management advice for the distant water fisheries at West Greenland and Faroes.

The groups were deemed appropriate by the Working Group as they fulfilled an agreed set of criteria for defining stock groups for the provision of management advice that were considered in detail at the 2002 meeting (ICES, 2002) and re-evaluated at the 2005 meeting (ICES, 2005). Consideration of the level of exploitation of national stocks at both the distant water fisheries resulted in the proposal that advice for the Faroes fishery (both 1SW and MSW) should be based upon all NEAC area stocks, but that advice for the West Greenland fishery should be based upon Southern NEAC non-maturing 1SW stock only.

### 3.6 Pre-fishery abundance forecasts

The Working Group previously used a regression model to forecast PFA of nonmaturing (potential MSW) salmon from the Southern NEAC stock group (ICES, 2002; 2003; 2009a). In 2009 this was superseded by a new forecast model developed in a Bayesian framework which produced forecasts for all four NEAC stock complexes. This model was used to produce forecasts in 2009 and 2010. In 2011 a revised version, including minor developments in the way in which PFA maturing and PFA non-maturing were calculated was used. The updated model was run in parallel with the previous model and forecasts were found to be comparable. Developments in the model are detailed in Section 3.7.2.

### 3.6.1 Description of the forecast model

In 2011 the Working Group ran forecast models for the Southern NEAC and Northern NEAC complexes. The model was run for each stock complex independently.

The PFA is modelled using the summation of lagged eggs from 1SW and MSW fish $(L E)$ for each year $t$ and an exponential productivity parameter (a).

$$
P F A_{t}=L E_{t}^{*} \exp \left(a_{t}\right)
$$

The productivity parameter $a$ is forecast one year at a time $\left(a_{t-1}\right)$ in an auto correlated random walk, using the previous year's value $(a)$ as the mean value in a normal distribution, with a common standard deviation of the time-series of $a$.

$$
a_{t+1}=N\left(a_{t}, \text { tau. } a\right)
$$

The maturing PFA (denoted PFAm) and the non maturing PFA (denoted PFAnm) recruitment streams are subsequently calculated from the proportion of $P F A$ maturing (p.PFAm) for each year $t$. p.PFAm is forecast as an auto correlated value from a normal distribution based on a logit scale, using the previous year's value as the mean and a common standard deviation across the time-series of p.PFAm.

```
logit.p.PFAm \(_{t+1} \sim N\left(\right.\) logit.p.PFAm \(_{t}\), tau.logit.p.PFAm)
logit. \(p \cdot P F A m t=\operatorname{logit}(p \cdot P F A m t)\)
```

Uncertainties in the lagged eggs were accounted for by assuming that the lagged eggs of 1SW and MSW fish were normally distributed with means and standard deviations derived from the Monte-Carlo run reconstruction at the scale of the stock complex. In the 2009 and 2010 assessments the reported uncertainties in the maturing and non-maturing PFA returns were those derived from the Monte-Carlo run reconstruction for years prior to 2010 and 2009 respectively. The uncertainties in these variables in the 2011 assessment are derived in the Bayesian forecast models.

Catches of salmon at sea in the West Greenland fishery (as 1SW non-maturing salmon) and at Faroes (as 1SW maturing and MSW salmon) were introduced as covariates and incorporated directly within the inference and forecast structure of the model. For Southern NEAC, the data were available for a 33-year time-series of lagged eggs and returns (1978 to 2010). For Northern NEAC, data were available for a 20 -year time-series, 1991 to 2010. The models were fitted and forecasts were derived in a consistent Bayesian framework.

For both Southern and Northern NEAC complexes, forecasts for maturing and nonmaturing stocks were derived for five years, from 2010 to 2014. Risks were defined each year as the posterior probability that the PFA would be below the age and stock complex specific SER levels. For illustrative purposes, risk analyses were derived
based on the probability that the PFA abundance would be greater than or equal to the SER under the scenario of no exploitation.

### 3.6.2 Results of the NEAC Bayesian forecast models

The trends in the posterior estimates of PFA for both the Southern NEAC and Northern NEAC complexes closely match the PFA estimates derived from the run reconstruction model (Section 3.8.12).

For the Southern NEAC stock complex, the productivity parameters for the maturing and non-maturing components peaked in 1985 and 1986, and reached the lowest values in 1997 and 1999 (Figure 3.6.2.1). There was a sharp drop in the productivity parameter during 1989 to 1991 and the median values post-1991 are all lower than during the previous time period.

Over the entire time-series, the maturing proportions averaged about 0.6 with the smallest proportion in 1980 and the largest proportion in 1998 (Figure 3.6.2.2). There is an increasing trend in the proportion maturing ( 8 of 13 values below the average during 1978 to 1990 compared with 4 of 17 values between 1991 and 2007). The total PFA (maturing and non-maturing 1SW salmon at January 1st of the first winter at sea) for the Southern NEAC complex ranged from 3 to 4 million fish between 1978 and 1989, declined rapidly to just over 2 million fish in 1990, and fell to its lowest level of just over 1.5 million fish in 2008 (Figure 3.6.2.4).

For the Northern NEAC complex, peak PFA abundance was estimated at about 2 million fish in year 2000 with the lowest value of the series in 2008 at over 1 million fish (Figure 3.6.2.5). The proportion maturing has varied around 0.55 over the time-series but in 2007 there was an abrupt drop in the proportion maturing to below 0.37 . This revealed some recovery in 2008 to around 0.43 however in 2009 was consistent with the previous two years, around 0.38, notably below the 1991 to 2006 level (Figure 3.6.2.2).

The productivity increased in 2009 in the Northern NEAC complex, though remained below pre- 2004 values, while in the Southern complex 2009 was comparable with 2008 and continued the slow decline from 2003, though in the same range as post1989 values (Figure 3.6.2.1).

Forecasts from these models into 2010 to 2014 for the non-maturing and maturing age group were developed within the Bayesian model framework. Variations in the median abundance over the forecasts are related to variations in lagged eggs (Figure 3.6.2.3) as the productivity parameter values are set at the level of the last year with available data (Figures 3.6.2.1). The variability in the productivity parameters increased sequentially over the forecasts.

For the Southern NEAC stock complex, the 25th percentiles of the posterior distributions of the forecasts are below the SER for the maturing age component, with the median points just above for years 2009 to 2014, with 2011 to 2014 being forecasts (Figures 3.6.2.4). For the non-maturing component the 25th percentile is just above the SER for the first forecast year (2010) and falls below it by the fifth forecast year (2014).

The abundances of the Northern NEAC age components have declined over the 1991 to 2009 time period (Figure 3.6.2.5). For the maturing component the lower limit of the confidence interval has fallen below the age-specific SERs for 2010 to 2014 and the 25 percentile has just remained above. For the non-maturing component of the stock,
forecasts are generally above the SER but with the lower limit of the confidence interval of forecast abundances falling below the SER in 2013 and 2014.

### 3.6.3 Probability of attaining PFA above SER

Probabilities that the PFAs will be above or equal to SERs in 2010 to 2014 from the Bayesian model are given in the table below. Probabilities of meeting SERs are higher in the Northern complex than in the Southern complex.

| Southern NEAC | Maturing |  | Non-maturing |
| :---: | :---: | :---: | :---: |
|  | SER | 793900 | 437525 |
| Year |  | p | p |
| 2010 |  | 0.508 | 0.810 |
| 2011 |  | 0.562 | 0.782 |
| 2012 |  | 0.543 | 0.734 |
| 2013 |  | 0.512 | 0.688 |
| 2014 |  | 0.589 | 0.732 |
| Northern NEAC |  | ing | Non-maturing |
|  | SER | 261359 | 222225 |
| Year |  |  | p |
| 2010 |  | 0.862 | 0.999 |
| 2011 |  | 0.800 | 0.994 |
| 2012 |  | 0.761 | 0.982 |
| 2013 |  | 0.765 | 0.974 |
| 2014 |  | 0.760 | 0.965 |

### 3.6.4 Use of the NEAC Bayesian forecast models in catch advice

In the absence of specific management objectives for the Faroes fishery, ICES requires that the lower bound of the $95 \%$ confidence interval of the PFA estimate be above the SER for the stock to be considered at full reproductive capacity. The Working Group noted that for both the Northern NEAC and Southern NEAC stock complexes the Bayesian models predict that the lower limit of the $95 \%$ confidence interval as being below the SER for both age groups in all years, except for the non-maturing component in 2010 to 2012 in the Northern NEAC complex.

It is also noteworthy that for the Southern NEAC maturing complex the 25th percentiles, in all instances, fall below the respective SER and the medians are just above SER. For the non-maturing component, the lower limit of the confidence interval is well below and the 25th percentiles are just below SER for the forecast years 2010 and 2011 and are well below in 2011 to 2014.

For the West Greenland Commission area, the risk level has been set to $75 \%$ (ICES 2009a).

### 3.7 Comparison with previous assessment

### 3.7.1 Changes to the NEAC PFA model and national conservation limit model

Provisional catch data for 2009 were updated where appropriate and the assessment extended to include data for 2010. In addition,

- The time-series of national exploitation rates for UK (England and Wales) was revised for both 1SW and MSW salmon. These data have been estimated by deriving time-series of 'standard fishing units' employed in the salmon fisheries for the time-series as a whole, weighted by their relative catching power and adjusted relative to average age-specific exploitation estimates derived for the 1997 and 1998 seasons. The 'standard fishing units' for the latter part of the time-series (1998 on) were updated, based on the numbers of days fished by different net categories rather than licence numbers as used previously. Licence numbers continue to be used in respect of the rod fishery. In addition, further efforts have been made to refine the average age-specific exploitation rates applied to the time-series as a whole.
- The number of regions used in respect of the Norway assessment was expanded from three to four by splitting the South region into Southeast and Southwest regions. This was done to better reflect the different stock status in these two regions in the overall assessment and reflects domestic management arrangements.

### 3.7.2 Changes to the NEAC PFA Bayesian forecast model

Improvements in the stock complex Bayesian PFA forecast models
The Bayesian PFA forecast models were run at the Northern NEAC and Southern NEAC stock complex levels. These runs were made with models containing minor improvements in structure and calculation processes relative to the models used in previous years. Changes were made to the models to improve the calculation run times and incorporate uncertainty around all the variables and parameters from the Run Reconstruction model. The details of model changes and their reasons included:

- The uncertainty in lagged eggs and returns is accounted for through the approximation of normal distributions, using means and standard deviations which are specified in the dataset. As a consequence, the uncertainties around PFAm and PFAnm over past years are modelled and monitored.
- The productivity parameter is forecast in an auto correlated random walk, around a normal distribution. This ensures that forecasts are more congruous with the past values.
- In the previous version two productivity parameters were calculated, for the maturing and non-maturing components of the PFA, each of which were then calculated, and summed to calculate total PFA. In the updated version only one productivity parameter is calculated, and used to calculate total PFA, which is then split into maturing and non-maturing PFA based upon the proportion of maturing PFA.
- The proportion of maturing PFA is forecast in an auto correlated random walk, around a normal distribution, transformed on a logit scale. This ensures that forecast proportions of maturing and non-maturing PFA are more in line with the past values.

To verify that the changes to the models were relatively minor, the versions of the models run in 2009 and 2010 were run in parallel with the revised 2011 recommended version. Differences in results were minimal (Figure 3.7.2.1 to 3.7.2.5).

## Comparison of results from the revised 2011 Bayesian forecast model and its predecessor

Only one productivity parameter (a) is estimated in the revised model, from which total PFA was estimated from Lagged Eggs. In the earlier version of the model two productivity parameters were calculated, non-maturing (anm) and maturing (am) (Figure 3.7.2.1). For both the Northern and Southern stock complex models these parameters tracked well over the time period. In the updated model the single productivity parameter is functionally a summation of the two productivity parameters of the previous version but uncorrected for the proportion maturing. The uncertainty is lower because the variance is estimated for only one parameter as opposed to the two (anm and am) in the previous version

The consequences of the revised model structure on the estimates of proportion of maturing 1SW is clear (Figure 3.7.2.2) with estimates increasing in uncertainty as forecast year interval increases and due to the inclusion of uncertainty from the inference portion of the model for years prior to 2010. Also notable is the positioning of the forecast series in line with the recent year (2009) estimate.

Estimates of the maturing PFA are consistent with the previous year's forecasts for both models (Figure 3.7.2.3). Uncertainty is greater in the new version, with medians, inter quartile ranges and 2.5 th percentiles being slightly lower.

For Northern NEAC, estimates of the non-maturing PFA from the revised model for the five forecast years are more consistent with the earlier time-series than from the previous model version (Figure 3.7.2.4), and consistent for Southern NEAC. Estimates tend to include greater uncertainty the further into the future the forecast is made

The original and revised models were compared by plotting outputs and respective error values (Figure 3.7.2.5). Higher relative error values for all the variables of interest in the inference portion of the model are due to the inclusion of the uncertainty of the returns estimates in the new version, these uncertainties had not been incorporated in the early version. Inferences on PFA are similar for maturing and non maturing components between the two model versions, as is the inference of the proportion maturing for both stock complexes (medians are all distributed along the 1:1 line) (Figure 3.7.2.5).

The largest differences are in the forecast values for PFA and proportion maturing, and particularly for the Northern NEAC complex (Figure 3.7.2.5). The first order autocorrelation dynamic introduced in the new version of the model shifts the forecast of the proportion maturing to the most recent year value rather than to the mean of the series value as was the case for the first version of the model. The consequences are apparent in the shift of the forecast probability of maturing for the Northern NEAC complex being at about 0.40 which gives a higher forecast for the nonmaturing PFA and a slightly lower forecast for the maturing PFA (Figure 3.7.2.5). When the large drop in proportion maturing was noted in the 2007 PFA of the Northern NEAC stock complex, it was thought to be anomalous but over the past three years of inference, the proportion maturing has remained lower than was inferred prior to 2007 (Figure 3.6.2.2).

### 3.7.3 Performance of the revised 2011 Bayesian forecast model

In 2010, a retrospective comparison of model forecasts was undertaken to investigate the NEAC Bayesian forecast model's ability to predict PFAs for maturing and nonmaturing recruits in both Northern and Southern NEAC stock complexes (ICES 2010b). This exercise was repeated in 2011. Run-reconstructed PFAs for 2009 were
compared with the model predictions. Data in the forecast model were successively truncated to allow forecasts to be run simulating the viewpoints for the years 2006 to 2010 (Figures 3.7.3.1 and 3.7.3.2). The year 2006 is the earliest for which lagged spawner estimates, derived from the run-reconstruction model, allow prediction of the 2009 PFA values. The 2010 forecast is necessary to predict PFAs for non-maturing stocks in 2009 as the MSW spawners for that cohort do not return until 2010 and abundance estimates are not available until 2011.

In all four stock complexes, the uncertainties associated with the forecasts generally decrease as the interval between reconstructed estimate and forecast year decreases. Median run-reconstructed PFA estimates generally lay within the interquartile range of model forecasts for that PFA cohort.

### 3.8 NASCO has requested ICES to describe the key events of the 2010 fisheries and the status of the stocks

### 3.8.1 Fishing at Faroes in 2009/2010

No fishery for salmon has been prosecuted since 2000.

### 3.8.2 Significant events in NEAC homewater fisheries in 2010

## UK (Northern Ireland)

In 2010 exploitation in UK (Northern Ireland) was further reduced by the closure of all net fisheries in the Foyle area.

## France

Reliable catch estimates, for both commercial and recreational net fisheries, on the Albâtre coast (northwest France) and Mont St Michel Bay (west France) areas continue to be unavailable. In addition, catches from a new coastal fishery in the southwest of the country, which began in 2009 and expanded in 2010, are also unreported. Catches from these three areas are estimated to be at least 500 fish which represents a fivefold increase in catch in coastal fisheries in 2010 compared with 2009. It was reported to the Working Group that the absence of catch statistics was a result of lack of enforcement of existing regulations.

## Ireland

During 2001 to 2009, catch statistics were collected by seven designated Regional Fisheries Boards around the Republic of Ireland. Statistics were collected directly from mandatory logbook reports from the commercial and recreational sectors. In 2010, a new body, Inland Fisheries Ireland, replaced the seven regional fisheries boards and the Central Fisheries Board and is now responsible for the collection of catch statistics.

## Norway

Although no further restrictions in coastal fisheries were applied in 2010, the number of licences in use for bag and bendnets in Norway continues to decline. The number of bag nets in use in the 2010 season was 760 , compared with 978 the year before, while the number of bendnets in use declined from 631 in 2009 to 493 . This decline is most likely due to low recruitment of new fishers as older fishers retire. Also, the reductions in the length of the fishing season in many areas during recent years may
have reduced the motivation of fishers in some regions to participate in the fishery. In 2010, a number of rivers in the Rogaland, Hordaland and Nordland counties were closed on the basis of low spawner numbers in 2009.

### 3.8.3 Gear and effort

No significant changes in gear type used were reported in 2010, however, changes in effort were recorded. The number of gear units licensed or authorized in several of the NEAC area countries provides a partial measure of effort (Table 3.8.3.1), but does not take into account other restrictions, for example, closed seasons. In addition, there is no indication from these data of the actual number of licences actively utilized or the time each licensee fished.

Trends in effort are shown in Figures 3.8.3.1 and 3.8.3.2 for the Northern and Southern NEAC countries respectively. In the Northern NEAC area, driftnet effort in Norway accounted for the majority of the effort expended in the early part of the timeseries. However, this fishery closed in 1989, reducing the overall effort substantially.

The numbers of gear units licensed from UK (England and Wales) and reported in UK (Scotland) (Table 3.8.3.1) have decreased and were among the lowest reported in the time-series. In Norway the number of bag nets has decreased for the past 15-20 years and was the lowest reported in the time-series. The number of bendnets has also decreased for the same period and was the lowest in the time period and additional restrictions on the numbers of days fished were introduced from 2008. The number of driftnet, draftnet, bag nets and boxes for UK (Northern Ireland) for 2010 was the lowest reported for the time-series.

Rod effort trends, where available, have varied for different areas across the timeseries (Table 3.8.3.1). In the Northern NEAC area the catch and release rod fishery in the Kola Peninsula in Russia has increased from 1711 fishing days in 1991 to 13604 in 2006 (no data were available for 2007-2010). In Finland the number of fishing days has demonstrated an increase throughout the time period but it was close to the five year average in 2010. In the Southern NEAC area rod licences in 2010 decreased from the previous year in UK (England and Wales). In Ireland there was an apparent increase in the early 1990s in rod fishing licences due to the introduction of one day licences and then remained stable for over a decade, thereafter decreasing from 2002 due to fishery closures. In France the effort has been fairly stable over the last 10 years.

### 3.8.4 Catches

NEAC area catches are presented in Table 3.8.4.1. The provisional declared catch in the NEAC area in 2010 was 1401 tonnes, the second lowest in the time-series but representing an increase of around $21 \%$ on the 2009 catch ( 1158 t ).

The provisional total nominal catch in Northern NEAC for 2010 ( 973 t ) rose by 9\% compared with 2009 but was $12 \%$ and $22 \%$ below the previous 5 and 10 year averages respectively. In the Southern NEAC area the provisional total nominal catch for 2010 ( 427 t ) rose by $62 \%$ compared with 2009 ( 264 t ) but was $13 \%$ and $46 \%$ below the previous 5 and 10 year averages respectively. Despite a noticeable increase in catches in 2010 over 2009 in the Southern NEAC area the catches are still below the long-term means in most countries which reflects significantly reduced fishing effort and possibly reduced stock abundance.

Figure 3.8.4.1 shows the trends in nominal catches of salmon in the Southern and Northern NEAC areas from 1971 until 2010. The catch in the Southern area has declined over the period from about 4500 t in 1972 to 1975 to below 1000 t since 2003 and was between 250-650 t over last 5 years. The catch revealed marked declines in 1976 and in 1989 to 1991. The catch in the Northern area also indicated an overall decline over the time-series, although this decrease was less distinct than the reductions noted in the Southern area. The catch in the Northern area varied between 2000 and 2800 t from 1971 to 1988, fell to a low of 962 t in 1997 and then increased to over 1600 t in 2001 although it has exhibited a downward trend since and is now below 1000 t . Thus, the catch in the Southern area, which comprised around two-thirds of the total NEAC catch in the early 1970s, has been lower than that in the Northern area since 1999.

### 3.8.5 Catch per unit of effort (cpue)

The cpue is a measure that can be influenced by various factors, such as fishing conditions/experience. It is assumed that the cpue of net fisheries is a more stable indicator of the general status of salmon stocks than rod cpue; the latter may be more affected by varying local factors, e.g. weather conditions, management measures and angler experience. Both may also be affected by measures taken to reduce fishing effort, for example, changes in regulations affecting gear. If large changes occur for one or more factors a common pattern may not be evident over larger areas. It is, however, expected that for a relatively stable effort, cpue can reflect changes in the status of stocks and stock size. The cpue may be affected by increasing rates of catch and release in rod fisheries which are not included in all recreational rod fisheries.

The cpue data are presented in Tables 3.8.5.1-3.8.5.5. The cpue for rod fisheries have been collected by relating the catch to rod days or angler season, and that of net fisheries was calculated as catch per licence-day, trap month or crew month.

In the Southern NEAC area, cpue has generally decreased in UK (England and Wales) and UK (Scotland) net fisheries (Figure 3.8.5.1). The cpue for net fisheries in 2010 demonstrated mostly higher figures compared with 2009 and the previous 5year averages (Table 3.8.5.3). In UK (Northern Ireland), the River Bush rod fishery cpue increased in 2010 but was less than the 5 -year average (Table 3.8.5.1). In France, the cpue for rod fisheries is higher than both the 2009 figure and the 5 -year average (Table 3.8.5.1).

In the Northern NEAC area, there has been an increasing trend in cpue for the Russian rod fisheries in both the Barents and White Sea rivers (Figure 3.8.5.1 and Table 3.8.5.2) and in the Norwegian net fisheries (Figure 3.8.5.1 and Table 3.8.5.5.). A decreasing trend was noted for rod fisheries in Finland (River Teno). Most 2010 cpue values increased compared with both 2009 and the previous 5-year means (Tables 3.8.5.1, 3.8.5.2, and 3.8.5.5).

### 3.8.6 Age composition of catches

The percentage of 1SW salmon in NEAC catches is presented in Table 3.8.6.1 and in Figures 3.8.6.1 (Northern NEAC) and 3.8.6.2 (Southern NEAC). The overall percentage of 1SW fish in the Northern NEAC area catch remained reasonably consistent in the period 1987 to 2000 (range 61 to $72 \%$ ), but has fallen in more recent years (range 50 to $69 \%$ ), when greater variability among countries has also been evident. In 2010, the percentage of 1SW fish in catches remained at the same level for Northern NEAC countries compared with 2009 ( $61 \%$ compared with $59 \%$ in 2009) and similar to the
previous 5- and 10-year averages. On average, 1SW fish comprise a higher percentage of the catch in Iceland and Russia than in the other Northern NEAC countries (Figure 3.8.6.1). The percentage of 1SW fish in the catches in Iceland has been increasing for a number of years, but the estimate for 2010 is somewhat lower than the three previous years. The percentage of 1SW in Norway, Sweden and Finland has been lowest among the Northern NEAC countries, but has increased in recent years.

In the Southern NEAC area, the overall percentage of 1SW fish in the catch (60\%) was equal to the previous 5- and 10-year means (59\%) and has remained reasonably consistent over the time-series (range 49 to $65 \%$ ), although there is considerable variability among individual countries (Figure 3.8.6.2). On average, 1SW fish comprise a larger proportion of the catch ( 70 to $80 \%$ ) in UK (England and Wales) than in the other Southern NEAC countries that provide data.

### 3.8.7 Farmed and ranched salmon in catches

The contribution of farmed and ranched salmon to national catches in the NEAC area in 2010 was again generally low in most countries, with the exceptions of Norway, Iceland and Sweden, and is similar to the values that have been reported in previous years (ICES 2009a). The occurrence of such fish is usually ignored in assessments of the status of national stocks (Section 3.8.11).

However, in Norway farmed salmon continue to form a large proportion of the catch in those fisheries which have been sampled ( $29 \%$ in coastal fisheries, $36 \%$ in fjordic fisheries in 2009 and $8 \%$ in rod fisheries in 2010). The number of coastal and fjordic fisheries sampled was lower in 2009 than in previous years and incidence of farmed fish in these fisheries is thought to be an overestimate of the overall picture for 2009, and in 2010 the number of marine fisheries sampled was too low to provide an estimate. The number of farmed salmon that escaped from the Norwegian farms in 2010 is reported to be 255000 fish (provisional figure). An assessment of the likely effect of these fish on the output data from the PFA model has been reported previously (ICES 2001).

The release of smolts for commercial ranching purposes ceased in Iceland in 1998, but ranching for rod fisheries in two Icelandic rivers continued into 2010. Icelandic catches have traditionally been split into two separate categories, wild and ranched, and in 2010, 36 t were reported as ranched salmon in contrast to 124 t harvested as wild.

Ranching occurs on a much smaller scale in other countries. Some of these operations are experimental and at others harvesting does not occur solely at the release site. In 2010, in Ireland less than 1t was reported as ranched salmon and this has been included in the nominal catch.

### 3.8.8 National origin of catches

## Catches of Russian salmon in Norway

Evidence of Russian origin salmon being caught in coastal mixed-stock fisheries in northernmost Norway have been reported in previous years (e.g. ICES 2009a). Norway has recently decreased fishing effort in coastal areas and available information reveals a decline in the number of fishing days and in the number of fishers operating in marine waters of Finnmark county. However, there are still salmon fisheries operating in this coastal area, which are very likely to exploit Russian salmon.

In 2009, a joint Russian and Norwegian project began, the aims of which included establishing a genetic baseline for characterization of salmon populations, which could be used for estimating the composition of mixed-stock fisheries in the area (see Section 2.3.8). Preliminary investigation of the composition of the mixed-stock fisheries indicate that the catches consist of a mix of salmon from a number of rivers in both countries, with the Russian component in Finnmark increasing from west to east. Also, the results demonstrate that bag nets located near the coast catch fish from a larger number of stocks than bag nets located in the fjords. This work will continue under the Joint Russian-Norwegian Scientific Research Program on Living Marine Resources in 2011 (Appendix 10 of the 39th Joint Russian-Norwegian Fishery Commission) and under the Kolarctic Salmon project (EU Kolarctic ENPI CBC programme) (see Section 2.3.8).

### 3.8.9 Developments to the NEAC-PFA and CL model

The Working Group has previously developed a model to estimate the pre-fishery abundance (PFA) of salmon from countries in the NEAC area. PFA in the NEAC area is defined as the number of $15 W$ recruits on January 1st in the first sea winter. The model estimates the PFA from the catch in numbers of 1SW and MSW salmon in each country. These are raised to take account of minimum and maximum estimates of non-reported catches and exploitation rates of these two sea-age groups. Finally these values are raised to take account of the natural mortality between January 1st in the first sea winter and the mid-point of the respective national fisheries. As reported in 2002 (ICES 2002), the Working Group has determined a natural mortality value of 0.03 (range 0.02 to 0.04 ) per month to be appropriate. A Monte Carlo simulation (10 000 trials) using 'Crystal Ball v7.2.1' in Excel (Decisioneering, 1996) is used to estimate confidence limits on the PFA values. Potter et al., 2004 provide full details of the model. Further modifications, to improve the model were incorporated during the Working Group meeting in 2005 (ICES 2005).

The Working Group has developed an updated version of the model which runs in the ' R ' software. The objective is to provide a more flexible platform for the further development of the model and to allow its integration with the Bayesian forecast model for the development of catch options. The new code has been run in parallel with the Excel/Crystal Ball model to validate the outputs, prior to making additional changes (ICES 2010b).

The transfer of the model to the R software has provided the opportunity to review the current model and consider changes. In addition to the minor corrections described in Section 3.7.1, various issues have been noted where the model (whether in Crystal Ball or R) might be improved and the outputs (figures and tables) modified in line with the provision of catch options.

### 3.8.10 National input to the NEAC-PFA model

To run the NEAC PFA model, most countries are required to input the following time-series information (beginning in 1971) for 1SW and MSW salmon:

- Catch in numbers,
- Unreported catch levels (min and max), and
- Exploitation levels (min and max)

The model input data are provided in Annex 5. For some countries, the data are provided in two or more regional blocks. In these instances, the model output is com-
bined to provide one set of output variables per country. The model input data for Finland consists solely of catches from the River Tana/Teno. These comprise both Finnish and Norwegian net and rod catches. The Norwegian catches from the River Tana/Teno are not included in the Norway data. The model input data for UK (England and Wales) exclude the estimated catches of Scottish fish in the NE English coastal fishery; these are incorporated into the assessment for UK (Scotland).

Descriptions of how the model inputs have been derived were presented in detail at the Working Group meeting in 2002 (ICES 2002). Modifications are reported in the year in which they are first implemented and significant modifications undertaken in 2010 are indicated in Section 3.7.1.

### 3.8.11 Description of national stocks as derived from the PFA model

The Working Group has previously noted that the NEAC PFA model provides our best interpretation of available information on national salmon stocks. However, there remains considerable uncertainty around the derived estimates, and national representatives are continuing to improve the data inputs each year on the basis of new data, improved sampling and further analysis.

The National CLs model has been designed as a means to provide a preliminary CL reference point for countries where river-specific reference points have not been developed. A limitation with a single national status of stocks analysis is that it does not capture variations in status in different fishery areas or stock complexes. This has been addressed, at least in part, by the area splits in some countries.

The model output for each country has been displayed as a summary sheet (Figures 3.8.11.1(a-j)) comprising the following:

- Estimated pre-fishery abundance (PFA) and SERs of maturing 1SW and non-maturing 1SW salmon.
- Estimated total returns and spawners (95\% confidence limits) and CLs for 1SW and MSW salmon.
- Total exploitation rate of 1SW and MSW salmon estimated from the total returns and total catches derived from the model.
- Estimated total catch (including non-reported) of 1SW and MSW salmon.
- National pseudo stock-recruitment relationship (PFA against lagged egg deposition), with CL fitted by the method presented in ICES (2001) for those countries where CLs are not estimated using river-specific CLs.

### 3.8.12 Trends in the PFA for NEAC stocks

Tables 3.8.12.1-3.8.12.6 demonstrate combined results from the PFA assessment for the NEAC area. The PFA of maturing and non-maturing 1SW salmon and the numbers of 1SW and MSW spawners for the Northern NEAC and Southern NEAC groups are shown in Figure 3.1.1.

The $95 \%$ confidence limits of the estimates (Figure 3.1.1) indicate the uncertainty in this assessment procedure. The Working Group recognized that the model provides an index of the current and historical status of stocks based upon simple catch and fisheries parameters (i.e. catch and exploitation rate). Errors or inconsistencies in the output largely reflect uncertainties in our best estimates of these parameters.

Recruitment patterns of maturing 1SW salmon and of non-maturing 1SW recruits for Northern NEAC (Figure 3.1.1) demonstrate broadly similar patterns. The general de-
cline over the time period is interrupted by a short period of increased recruitment from 1998 to 2003. Both stock complexes have been at full reproductive capacity prior to the commencement of distant water fisheries throughout the time-series.

Trends in spawner numbers for the Northern stock complexes for both 1SW and MSW are similar. Throughout most of the time-series, both 1SW and MSW spawners have been either at full reproductive capacity or at risk of reduced reproductive capacity. In 2010, both the 1 SW and 2SW spawner estimates indicated that the stock complex was at full reproductive capacity.

Recruitment patterns of maturing 1SW salmon and of non-maturing 1SW recruits for Southern NEAC (Figure 3.1.1) demonstrate broadly similar declining trends over the time period. The maturing 1SW stock complex has been at full reproductive capacity over most of the time period with the exception of 2009, when it was at risk of suffering reduced reproductive capacity prior to the commencement of distant water fisheries. The non-maturing 1SW stock has been at full reproductive capacity over most of the time period but has been at risk of suffering reduced reproductive capacity before any fisheries took place in two (2006 and 2008) of the last four PFA years.

Declining trends in spawner numbers are evident in the Southern NEAC stock complexes for both 1SW and MSW. The 1SW stock has been at risk of reduced reproductive capacity or suffering reduced reproductive capacity for most of the time-series. In contrast, the MSW stock has been at full reproductive capacity for most of the time-series until 1997. Thereafter the stock was either at risk of reduced reproductive capacity or suffering reduced reproductive capacity with the exception of 2004 and 2010 when the stock was at full reproductive capacity.

The trends in recruitment described above are broadly consistent with the general pattern of decline in marine survival of 1SW and 2SW returns in most monitored stocks in the area (Section 3.8.13).

### 3.8.13 Survival indices for NEAC stocks

An overview of the trends of marine survival for wild and hatchery-reared smolts returning to homewaters (i.e. before homewater exploitation) is presented in Figure 3.8.13.1. The survival indices are the percent change in return rate between five year averages for the periods 2000 to 2004 and 2005 to 2009 for 1SW salmon, and 1999 to 2003 and 2004 to 2008 for 2 SW salmon. The annual survival indices for different rivers and experimental facilities are presented in Tables 3.8.13.1 and 3.8.13.2. Return rates of hatchery released fish, however, may not always be a reliable indicator of marine survival of wild fish.

The overall trend for hatchery smolts in Northern and Southern NEAC areas is indicative of a decline in marine survival. For the wild smolts this decline is also apparent for the Northern NEAC areas; however for the Southern NEAC areas data are more variable with some rivers revealing an increase in survival whilst other rivers reveal a decrease. The percentage change between the means of the five year periods varied from a $97 \%$ decline to a $226 \%$ increase in one river (Figure 3.8.13.1). However, the scale of change in some rivers is influenced by low total return numbers, where a few fish more or less returning may have a significant impact on the percent change. Most of the survival indices for wild and reared smolts were below the previous 5 and 10-year averages (Tables 3.8.13.1 and 3.8.13.2). The return of wild 1SW salmon to Ellidaar River in Iceland was higher than both the 5 -year and 10-year averages, though slightly lower than the return in 2008. Also the returns of both 1SW and 2SW
wild salmon to North Esk were above the 5-year and 10-year averages. An increase in survival (226\%) was also detected in Iceland for hatchery reared grilse on the Ranga River (Table 3.8.13.2).

Comparison of survival indices for the 2008 and 2009 smolt years demonstrate a general increase for 2009 compared with 2008 for wild smolts in Northern and Southern NEAC areas, with the exception of the rivers Ellidaar and Vesturdalsa in Iceland. Return rates of wild smolts to the river Bresle of 1SW fish were exceptionally high in 2010 (Table 3.8.13.1). In the Irish river Corrib survival indices were unchanged. Survival indices for hatchery smolts in the Northern NEAC area for the 2009 smolt year demonstrated a decrease relative to 2008. In the Southern NEAC area survival indices for hatchery smolts increased in the same period, except for the Irish rivers Lee and Shannon, for which the survival indices remained unchanged.

Results from these analyses are consistent with the information on estimated returns and spawners as derived from the PFA model (Section 3.8.12), and suggest that returns are strongly influenced by factors in the marine environment.

### 3.8.14 Exploitation indices for NEAC stocks

Exploitation estimates have been plotted for 1SW and MSW salmon from the Northern NEAC (1983 to 2010) and Southern NEAC (1971 to 2010) areas and are displayed in Figures 3.8.14.1 and 3.8.14.2.

National exploitation rates are an output of the NEAC PFA Run Reconstruction Model. These were combined as appropriate by weighting each individual country's exploitation rate to the reconstructed returns. Previously (e.g. ICES 2010b) the stock complex exploitation rates presented were not weighted by national stock abundance.

Data gathered prior to the 1980s represent estimates of national exploitation rates whilst post 1980s exploitation rates have often been subject to more robust analysis informed by projects such as the national coded wire programme in Ireland. The overall rate of change of exploitation within the different countries in the NEAC area has been presented as a plot of the change (\% change per year) in exploitation rate over the time-series. This was derived from of the slope of the linear regression between time and natural logarithm transformed exploitation rate (Figures 3.8.14.3 and 3.8.14.4).

The exploitation of 1SW salmon in both Northern NEAC and Southern NEAC areas has demonstrated a general decline over the time-series (Figure 3.8.14.1 and 3.8.14.2), with notable sharp decline in 2007 as a result of the closure of the Irish driftnet fisheries in the Southern NEAC area. The weighted exploitation rate on 1SW salmon in the Northern NEAC area was $40 \%$ in 2010 representing a decline from the previous 5year $(44 \%)$ and 10 -year ( $45 \%$ ) averages. Exploitation on 1 SW fish in the Southern NEAC complex was $14 \%$ in 2010 indicating a decrease from both the previous 5-year $(21 \%)$ and the 10 -year ( $27 \%$ ) averages.
The exploitation rate of MSW fish also exhibited an overall decline over the timeseries in both Northern NEAC and Southern NEAC areas (Figures 3.8.14.1 and 3.8.14.2), with a notable sharp decline in 2008 as a result of significant changes in the Norwegian fisheries in the Northern NEAC area. Exploitation on MSW salmon in the Northern NEAC area was $45 \%$ in 2010, representing a decrease from the previous 5year ( $54 \%$ ) and 10-year averages ( $55 \%$ ). Exploitation on MSW fish in Southern NEAC
was $13 \%$ in 2010, a decrease from both the previous 5 -year ( $15 \%$ ) and 10 -year ( $18 \%$ ) averages.

The relative rate of change of exploitation over the entire time-series is plotted for the Northern NEAC stock complex in Figure 3.8.14.3. This indicates an overall reduction of exploitation in most countries for 1SW and MSW salmon. Exploitation of 1SW fish in Finland has been relatively stable over the time period whilst the largest rate of reduction has been for 1SW salmon in Russia. The Southern NEAC countries have also demonstrated a general decrease in exploitation rate (Figure 3.8.14.4) on both 1SW and MSW components. The greatest rate of decrease displayed for both 1SW and MSW fish was in UK (Scotland) whilst France and Iceland SW demonstrated relative stability in exploitation rates for both 1SW and MSW salmon during the timeseries.

### 3.9 NASCO has asked ICES to further investigate opportunities to develop a framework of indicators or alternative methods that could be used to identify any significant change in previously provided multi-annual management advice

In 2006, ICES provided multi-annual management advice for all three NASCO Commission Areas and presented a preliminary framework (Framework of Indicators FWI) which would indicate if any significant change in the status of stocks used to inform the previously provided multi-annual management advice had occurred. This FWI was subsequently developed further at the Study Group on Establishing a Framework of Indicators of Salmon Stock Abundance [SGEFISSA] in November 2006 (ICES 2007b).

The Working Group (ICES 2007c) developed a FWI for the Greenland fishery based on the seven contributing regions/stock complex with direct links to the three management objectives established by NASCO for that fishery. However, SGEFISSA was unable to develop a FWI for the Faroese fishery for a number of different reasons. Among these were the lack of quantitative catch advice, the absence of specific management objectives and a sharing agreement for this fishery and the fact that none of the available indicator datasets met the criteria for inclusion in the FWI. The Working Group (ICES 2007c) endorsed the SGEFISSA report of applying the FWI in respect of the West Greenland and North American Commissions. However, in the absence of a FWI for the Faroese fishery, it was recommended that annual assessments be conducted to update the multiyear catch advice.

In 2009 (ICES 2009a) the Working Group updated the NEAC datasets previously examined in the FWI. However, these still did not satisfy the criteria for inclusion in the FWI as being informative of a significant change, because over the time-series the PFA estimates have predominately remained above the SER. The Working Group decided that these datasets would need to be re-evaluated for use in future, should PFA estimates decline to levels consistently below the limit reference points for each stock complex. Alternatively, different approaches to that applied in respect of the Greenland fishery should be explored.

In 2010 the Working Group concluded that, as NEAC stocks remained close to their respective SERs, none of the available indicator datasets would meet the criteria for inclusion in the FWI and, additionally, as no alternative approaches had been proposed, the only indication of a change in the status of stocks would be provided by a full assessment of the NEAC stock complexes (ICES 2010b).

In 2011 the Working Group re-evaluated the approach for developing a FWI for the Faroese fishery. Because over the time-series the PFA estimates for the NEAC stock complexes have predominately remained above the SER, the working group suggested a different set of decision rules for this FWI. It was suggested that the status of stocks should be re-evaluated if the FWI suggests that the PFA estimates are deviating substantially from the median values from the forecast. Several criteria for when the PFA deviate substantially from the forecast were explored. It was suggested that the $95 \%$ confidence interval range of the indicator prediction relative to the median forecast value be used to compute those thresholds. The limits should be computed at the median values of the PFA forecasts in each of the years in a multiyear advice. In the event of a closed fishery, the indicators should be compared with the upper $95 \%$ confidence limit, and in the event of an open fishery they should be compared with both the upper and lower $95 \%$ confidence limits (see Figure 3.9.1 for an example).

To be included in the FWIs an indicator must fulfil two criteria: it must be a reliable predictor of the relevant PFA ( $\mathrm{r}^{2}$ from the regression larger than 0.20 ), and the value of the indicator (or a preliminary value) must be available for the inclusion in the FWI evaluation by mid-January. Of the possible 38 indicators that were evaluated during the 2011 meeting, $28(74 \%)$ were assessed to be relevant predictors of PFA, and 10 ( $26 \%$ ) were rejected. Of the retained indicators eight were from Northern NEAC and 20 from Southern NEAC (Table 3.9.1).

A spreadsheet for FWIs for each of the stock complexes was developed and tested.
Until alternative management units are agreed it is recommended that the indicators be regressed against the stock complexes to which they belong. For example MSW indicators from Norway should be regressed against PFA MSW for Northern NEAC. It is recommended that this procedure should be developed further and that new possible indicators should be brought forward to the Working Group before the next assessment in 2012. Depending on the success of the new suite of indicators to predict relevant PFAs, and that they can be made available at a relevant time (before 15th of January), a FWI could be suggested to NASCO in next year's working group report.

For a fishery to be opened or to remain open there should be a high probability that all four stock complexes would meet their CLs, and any indication that there has been a change in PFA from the forecast median value would trigger an assessment. If very few indicators are available to run the FWI by the agreed time, this would automatically trigger an assessment for the coming year.

### 3.10 NASCO has asked ICES to provide a more detailed evaluation of the choice of appropriate management units to be used in a risk based framework for the provision of catch advice for the Faroese salmon fishery, taking into account relevant biological and management considerations and including, if possible, worked examples of catch advice.

### 3.10.1 Background

For a number of years, NASCO has asked ICES to provide catch options or alternative management advice 'with an assessment of risks relative to the objective of exceeding stock conservation limits' for salmon in the NEAC area. In 2010, ICES (2010b) outlined a risk framework that could be used to provide and evaluate catch options for the Faroes fishery based on the method currently used to provide catch advice for
the West Greenland fishery. The risk framework for the West Greenland fishery involves estimating the uncertainty in meeting defined management objectives at different catch levels (TAC options).

ICES (2010b) described the procedure for conducting such an assessment and noted that the following three issues would require decisions by managers before full catch advice could be provided:

- the choice of management units for NEAC stocks;
- the specification of management objectives;
- the share arrangement for the Faroes fishery.

The approach would then involve estimating the probability of stocks achieving the management objective in each of the NEAC area Management Units. The catch advice would display the probability of the stock in each Management Unit achieving its management objective for different Total Allowable Catch (TAC) options in the Faroes fishery and could be presented in tabular and graphic form.

The NEA Commission discussed the above questions at its 2010 annual meeting and during intersessional discussions but has not reached any conclusion. NASCO therefore submitted the following additional question to ICES in February 2011: 'Provide a more detailed evaluation of the choice of appropriate management units to be used in a risk based framework for the provision of catch advice for the Faroese salmon fishery, taking into account relevant biological and management considerations and including, if possible, worked examples of catch advice.' In this section, the proposed risk framework is explored in more detail, a number of issues including the choice of management units are discussed, and a worked example of catch advice is provided in Section 3.10.8.

### 3.10.2 Faroes fishing season

The Working Group noted that the first issue to be resolved is the period to which any TAC for the Faroes fishery would apply. The Faroes fishery has historically operated between October/November and May/June, but the historical TACs applied to a calendar year. This means that two different cohorts of salmon of each age class (e.g. two cohorts of 1SW salmon, etc) were exploited under each TAC. While ICES could continue to provide catch advice on the basis of calendar year TAC options, allocating each stock forecast between two fishing periods would add another level of uncertainty to the advice. The Working Group therefore recommends that NASCO should manage any fishery on the basis of fishing seasons operating from October to June, and catch advice should be provided on this basis. This approach has been assumed in the examples provided in this report, although it should be noted that the advice would take exactly the same form if it was provided on a calendar year basis.

### 3.10.3 Choice of management units

ICES (2010b) noted that the stock complexes currently used for the provision of NEAC catch advice (Southern NEAC and Northern NEAC) are significantly larger than each of the six management units used for North American salmon (2SW only) in the catch advice for the West Greenland fishery. Basing an assessment of stock status on these large units greatly increase the risks to individual NEAC river stocks or groups of stocks that are already in a more depleted state than the average. However, having management units of a similar size (in numbers of fish) to those used for North America would require more than 50 units which would make the provision
and determination of catch options unwieldy and impractical. ICES (2010b) therefore noted that it would be necessary to find a compromise between the number of management units and their size and distribution.

The choice of management units may be influenced by both biological and political considerations as well as by practical issues such as the availability of data. Management which requires meeting CLs for individual stocks would require basing the management of a mixed-stock fishery on the status of each individual river stock (or population) that it exploits, possibly split by sea age group. Applying such an approach to the management of the Faroes fishery would result in $>3000$ management units in the NEAC area (i.e. at least two age groups in each of $\sim 1500$ rivers). Larger management units might be defined on biological grounds, such as commonalities in migratory patterns of stocks or other biological characteristics, but insufficient data are available to determine such groupings at present.

From a jurisdictional perspective, there is likely to be a strong preference for splitting the management units to at least the national level because of the different management regimes adopted by jurisdictions.

The development of catch advice is also constrained by the availability of data. The run-reconstruction (RR) model, which is used to estimate PFA and national CLs was initially broken down to the national level. This reflected the different ways that data are collected on stocks and fisheries in different countries and the ease with which parameter values for the model could therefore be derived. The assessment for some countries has since been broken down further where there are thought to be marked differences in parameter values (e.g. exploitation rates) between the regions. The RR model can, in theory, be run for individual rivers, but estimates of exploitation rates and unreported catches required for the model are not normally available at this level and there is no benefit in sub-dividing the assessment between areas for which the same parameter values would be used.

The assessment of TAC options also requires data on the size and age composition and origin of the catch. Some data are available from historical sampling in the Faroes fishery when it operated in the 1980s to 1990 s, but data on the origin of the catch are limited. The Working Group currently uses proportions derived from historical smolt and adult tagging studies to divide the Faroese catch between countries of origin in the RR model (Table 3.10.3.1). While the overall pattern appears reasonable, the results are relatively imprecise and some gaps (which arise from lack of tags) appear inconsistent with our general understanding of the stocks (e.g. zero proportion for Finnish MSW stock). The approximate nature of these estimates is not critical in the RR analysis, particularly since there has been little or no catch at Faroes for more than a decade, but it has a much more significant impact on the evaluation of catch options going forward. More precise estimates of stock composition could be obtained using genetic stock identification techniques on either historical (e.g. scales) or future samples collected in the fishery.

There therefore appears to be a conflict between the desire to define the NEAC management units at the jurisdiction level or below and the restrictions of the data which probably limit us to defining management units between the levels of jurisdictions and the currently used stock complexes. These management units would also be split into age groups (1SW and MSW).

The main problem with allocating catch to management units relates to the difficulty of estimating the contribution of the management units for which there are limited
tag recoveries (e.g. UK (Northern Ireland), France, Finland). A compromise that would partly resolve this problem could be to amalgamate geographically neighbouring units.

### 3.10.4 Management objectives

The management objectives provide the basis for determining the risks to stocks in each management unit associated with different catch options. However, NASCO has not provided management objectives for the Faroes fishery. The NASCO agreement on the adoption of a Precautionary Approach (NASCO, 1998) indicates that salmon fisheries should be managed by means of CLs and management targets and also calls for the 'formulation of pre-agreed management actions in the form of procedures to be applied over a range of stock conditions'. This suggests that the management objectives (e.g. the required probability of exceeding the CL) should be agreed in advance of specific management proposals being considered. Nevertheless, the proposed presentation of the catch options would permit managers to review the risk that different TAC options would pose to individual management units and choose a risk level that they consider appropriate.

The Working Group also considered the implications of basing the risk framework on overall abundance objectives for management units comprising large numbers of river stocks. Even setting management units at the jurisdiction level would mean that (at least) four management units (i.e. Ireland, Norway, Russia and (UK Scotland)) would each comprise over one hundred river stocks. Thus it would still be possible for large numbers of river stocks to be below CL while the management unit as a whole was meeting its management objective. If the management unit is set at the stock complex level, the problem would be greater, and it would be possible, for example, for the status of river stocks in a jurisdiction with many salmon rivers to completely mask the status of the stocks in a jurisdiction with fewer rivers.

The Working Group therefore proposed that an additional management objective should be applied to all management units based on the status of individual stocks. For example, this objective might state that for each of the management units an agreed percentage of the assessed river stocks must be meeting specified management objectives before a TAC is allocated to the mixed-stock fishery at Faroes. The criteria for judging satisfactory compliance with these requirements would need to be agreed by managers.

### 3.10.5 Sharing agreement

The 'sharing agreement' will establish the proportion of any harvestable surplus within the NEAC area that could be made available to the Faroes fishery through the TAC. In effect this means that for any TAC option being evaluated for the Faroes, it is assumed that the total harvest would be the TAC divided by the Faroes share.

The management framework for the West Greenland fishery provides a precedent for setting a share allocation based upon the historical split of declared catches at West Greenland and in North America using a baseline period of 1986-1990 (catches in West Greenland are lagged one year back). ICES (2010b) indicated that same method could be used to establish the share arrangement for the Faroes fishery, and because some stocks are exploited at both Faroes and West Greenland, suggested that it might be appropriate to use the same baseline period. On this basis, the share allocations would be $7.5 \%$ to Faroes, $7.1 \%$ to West Greenland and $85.4 \%$ to all NEAC homewater fisheries (Table 3.10.5.1 and Figure 3.10.5.1).

NASCO has not provided a share allocation, but one Party had proposed an alternative baseline period of 1984-1988. The share allocations based on this period would be $8.4 \%$ Faroes, $5.2 \%$ West Greenland and $86.4 \%$ all NEAC homewater fisheries (Table 3.10.5.1 and Figure 3.10.5.1). In the absence of an agreed share allocation, a value of $8 \%$ for the Faroes fishery has been used in this example.

The Faroes and West Greenland share allocations do not have to be based on the same baseline period, but any variance would have to be accommodated in an adjustment to the homewater share. Any share allocation established between West Greenland and NEAC stocks could be based on MSW stocks alone.

### 3.10.6 Evaluation of catch options

The process for assessing each catch option within the risk framework would be as follows. Parameters marked with an ${ }^{\prime * \prime}$ in the equations have uncertainty around them (see Section 3.10.7) and so contribute to the estimation of the probability density function around the potential total harvest arising from each TAC option.

The TAC option (T) is first divided by the mean weight $(\mathrm{W})$ of salmon caught in the Faroes fishery to give the number of fish (N) that would be caught; thus:

$$
\mathrm{N}=\mathrm{T} / \mathrm{W}^{*}
$$

This value is converted to numbers of wild fish (Nw) by multiplying by one minus the proportion of farm escapees in the Faroes catch (pE) observed in historical sampling programmes:

$$
N w=N x\left(1-\mathrm{pE}^{*}\right)
$$

This value is split into numbers by sea age classes (1SW and MSW) according to the proportion of each age group ( pAi ) observed in historical catch sampling programmes at Faroes, and the discards that die (i.e. $80 \%$ of fish less than 60 cm TL ) are added to the 1SW catch. Thus:

$$
\text { Nw1SW = Nwtotal x pA1SW* }+\left(\text { Nwtotal } \times \mathrm{pD}^{*} \times 0.8\right)
$$

and
NwMSW = Nwtotal x pAMSW*
where ' pD ' is the proportion of the total catch that is discarded (i.e. $<60 \mathrm{~cm} \mathrm{TL}$ ).
Further corrections are made to the 1SW and MSW numbers to reduce the 1SW total to take account of the proportion that will not mature as grilse and to add the survivors from this group to the MSW fish in the following year. For the first catch advice year the number added to the MSW total is adjusted to the TAC applying in the current year (i.e. zero in 2011). Thus
Nw1SW = Nw1SW x pM *
and
NwMSW = NwMSW + Nw1SW x (1-pM*) x e-12m
where ' pM ' is the proportion of 1 SW salmon that are expected to mature in the same year (0.78) and ' $m$ ' is the instantaneous monthly rate of mortality.

The numbers in each age group are then divided among the management units by multiplying by the appropriate proportions ( pUj ), where ' i ' denotes the age groups and ' j ' denotes the management units:
Nwij = Nwi x pUj

Finally, each of these values is raised by the Faroes share allocation (S) to give the total potential harvest (Hij) of fish from each management unit and sea age group.

$$
\mathrm{Hij}=\mathrm{Nwij} / \mathrm{S}
$$

These harvests are then subtracted from the stock forecasts (PFAij) for the management units and sea age groups and compared with the Spawner Escapement Reserves (SER) to evaluate attainment of the management objective. In practice the attainment of the management objective is assessed by determining the probability that PFAij - Hij - SERij is greater than zero.

The SER is the number of fish that need to be alive at the time of the Faroes fishery to meet the CL when the fish return to homewaters; this equals the CL raised by the mortality over the intervening time. CLs and SERs are currently estimated without uncertainty.

### 3.10.7 Input data for the risk framework

NASCO has asked ICES to provide worked examples of catch advice. On the basis of the above evaluation, the Working Group decided to provide an example of the risk framework based on the stock complexes previously used for the provision of catch advice. The assessment requires input data as described in Section 3.10.6. Some of these parameters (e.g. mean ages and weights, discard rates, etc.) apply to the catch that might occur at the Faroes if a TAC was allocated. In most cases the only data available to estimate these parameters comes from sampling programmes conducted in commercial and research fisheries in Faroese waters in the 1980s and 1990s.

Mean weights: Mean weights of salmon caught in the commercial and research fisheries operating in Faroese waters between 1983/84 and 1995/96 varied between 3.06 and 5.23 kg (Table 3.10.7.1 and Figure 3.10.7.1 ) (ICES 1997). However, high values were observed at the beginning of the time-series when part of the catch was taken to the north of the Faroes EEZ, and the values for the latter part of the series are based on relatively small catches in a research fishery which may not be as representative of a full commercial fishery. As a result, mean weights have been drawn randomly from the observed values of the 1985/1986 to 1990/1991 fishing seasons.

Proportion by sea age: The age composition of catches in the Faroes fishery has been estimated from samples collected in the 1983/1984 to 1994/1995 fishing seasons (Table 3.10.7.2 and Figure 3.10.7.2) (ICES, 1996b). The samples taken between 1991/1992 and 1994/1995 were from the research fishery and included potential discards but excluded farm escapees. As a result, values have been drawn from the observations between 1985/1986 and 1990/1991 to provide a probability distribution for this parameter. However, the age composition of the catches may be expected to be related to the mean weight (Figure 3.10.7.3). To take account of this relationship, the values of mean weight and age composition used in each sample run have been drawn from the same years.

Discard rates: In the past, there has been a requirement to discard any fish less than 60 cm total length caught in the Faroes fishery and discard rates have been estimated from the proportions of fish less than 60 cm in catch samples between the 1982/1983 and 1994/1995 seasons (ICES, 1996b) (Table 3.10.7.3); 80\% of these fish were expected to die (ICES, 1986). A probability distribution for the discard rate has been estimated by sampling at random from the annual values seen over for the same period as for the other parameters above.

Proportions of fish-farm escapees: The proportion of fish-farm escapees in the catches at Faroes has also been estimated from samples taken in the 1980/1981 to 1994/1995 fishing season (ICES, 1996b). However, the Working Group is aware that there have been substantial changes in the production of farmed fish and in the incidence of escape events. Data were also available to the Working Group on the proportion of farm escapees in Norwegian coastal waters between 1989 and 2008; the proportion in recent years (2002-2008) was $63 \%$ of the proportion during the period 1989/1990 to 1994/1995 when the sample time-series overlap (Table 3.10.7.4). The probability distributions of proportion of farm escapees used in the risk framework has therefore been generated by multiplying the rates observed in the Faroes fishery between 1988/1989 to 1994/1995 by 0.63 and then drawing sample values at random.

Proportions of catches by management unit: The origin of the stocks exploited at Faroes has been estimated from smolt and adult tagging studies and an approximate split between jurisdictions has been employed in the NEAC RR model (e.g. ICES, 2010b). These same proportions have been used to develop the risk framework, but because of the uncertainties described in Section 3.10.3, they have been grouped at the stock complex level. Thus 1SW salmon are assigned $50 \%$ to Northern NEAC and $50 \%$ to Southern NEAC area. MSW salmon are assigned $60.5 \%$ to Northern NEAC and $27.5 \%$ to Southern NEAC; the remaining $12 \%$ of MSW salmon were estimated to derive from other jurisdictions not currently included in the assessment (e.g. including Spanish and North American stocks).

Other input parameters are displayed in Table 3.10.7.5.

### 3.10.8 Worked example of the risk framework

The methods and data described above have been used to provide an example of the risk framework for the Northern and Southern NEAC stock complexes using the PFA forecasts derived from the Bayesian model described in Section 3.6. The results are presented as an example of how future catch advice might be provided, and do not constitute formal catch advice at this stage. The assessment was run using 10000 sample draws when generating probability distributions for the input parameters. Probability distributions for the PFA forecasts were derived from the mean and sd of the forecast model outputs using a lognormal distribution.
In the example, the probability of the stock complexes in Northern and Southern NEAC areas achieving their SERs (the overall abundance objective) for different catch options in the Faroes fishery (from 0 to 500 t) in 2012 to 2014 are indicated in Table 3.10.8.1 and Figure 3.10.8 .1. This assumes that the same TAC is applied and is taken in each of the three years. This indicates that there are no TAC options that will permit all stock complexes to have a greater than $75 \%$ probability of achieving their SERs in any year from 2012-2014. The flatness of the curves in the catch options figures is a function of the uncertainty in the estimates and the level of exploitation on the stocks in the Faroes fishery (Table 3.10.8.2 and Figure 3.10.8.2); more uncertain data and lower exploitation rates generate flatter curves.

Section 3.10.4 above discusses the problem of basing this form of risk analysis on management units comprising large numbers of river stocks and proposes that an additional management objective should also be applied at a smaller geographical scale if the management units are defined at the jurisdiction or stock complex level. This objective might state that an agreed percentage of the assessed river stocks within each of the smaller geographic units must be meeting specified management objectives before a TAC is allocated to the mixed-stock fishery at Faroes. Table
3.10.8.3 provides examples of the type of data that might be used in such an assessment, but the Working Group noted that stock status indicators should be based on the attainment of CLs before exploitation.

The Working Group recommends that further work be undertaken to check the appropriateness of the various data inputs, including seeking original datasets from the sampling programmes in the Faroes, and to define the management objectives based on individual river stocks.

Table 3.3.2.1. Conservation limits for NEAC stock groups estimated from national lagged egg deposition model and from river-specific values (where available).

${ }^{14}$ Lower Adour only since 1994 (Southwesten France), due to fishery closure in the Loire Basin.
Adour estuary only (Southwester France).
Number of isherin
and sea trout introduced in 1986 , leading to a short-term increase in the number of licences isuled.
Before 2000, equal to the number of salmon licenses sold. From 2000 onwards, number estimated because of a single sea rout and salmon angling license.
(2010/mean - 1 ) ${ }^{100}$

Table 3.8.4.1. Nominal catch of salmon in NEAC Area (in tonnes round fresh weight), 1960 to 2010 (2010 figures are provisional).

## 4 North American commission

### 4.1 Status of stocks/exploitation

In 2010, 2 SW spawner estimates for the six geographic areas indicated that all areas were below their conservation limit (CL) (Figure 4.5.2.3) and are suffering reduced reproductive capacity.

The estimated exploitation rate of North American origin salmon in North American fisheries has declined (Figure 4.4.6.1) from approximately $80 \%$ in 1971 to $15 \%$ in 2010 for large salmon and from approximately $68 \%$ in 1973 to $19 \%$ in 2010 for small salmon. Exploitation rates in 2010 on both size groups remained among the lowest in the time-series, although exploitation rates on small salmon have increased slightly since 2007. Exploitation rates on 2 SW equivalents have also been at about $15 \%$ over the past twelve years (Table 4.4.2.1).

The stock status is elaborated in Section 4.5.

### 4.2 Management objectives

Management objectives are described in Section 1.4.

### 4.3 Reference points

There are no changes to the 2 SW salmon CLs from those identified previously. CLs for 2SW salmon for Canada total 123349 and for the USA, 29 199, for a combined total of 152548

| Country and <br> Comission Area | Stock Area | 2SW spawner <br> requirement |
| :--- | :--- | :---: |
|  | Labrador | 34746 |
|  | Newfoundland | 4022 |
|  | Gulf of St Lawrence | 30430 |
|  | Québec | 29446 |
| Canada Total | Scotia-Fundy | 24705 |
| USA |  | 123349 |
| North American Total |  | 29199 |

### 4.4 NASCO has requested ICES to describe the key events of the 2010 fisheries

### 4.4.1 Key events of the 2010 fisheries

- The majority of harvest fisheries were directed to small salmon.
- 2010 harvest was 54116 small salmon and 10988 large salmon, $26 \%$ more small salmon and $2 \%$ less large salmon compared with 2009.
- Catches remain very low relative to pre 1990 values.

### 4.4.2 Harvest of North American salmon, expressed as 2 SW salmon equivalents

Harvest histories (1972 to 2010) of salmon, expressed as 2 SW salmon equivalents are provided in Table 4.4.2.1. The Newfoundland-Labrador commercial fishery historically was a mixed-stock fishery and harvested both maturing and non-maturing 1SW salmon as well as 2 SW maturing salmon. The harvest in these fisheries of repeat spawners and older sea ages was not considered in the run reconstructions.
Harvests of 1SW non-maturing salmon in Newfoundland-Labrador commercial fisheries have been adjusted by natural mortalities of $3 \%$ per month for 13 months, and 2SW harvests in these same fisheries have been adjusted by one month to express all harvests as 2 SW equivalents in the year and time they would reach rivers of origin. The Labrador commercial fishery has been closed since 1998. Harvests from the Aboriginal Peoples' fisheries in Labrador (since 1998) and the residents' food fishery in Labrador (since 2000) are both included. Mortalities in mixed-stock and terminal fisheries areas in Canada were summed with those of USA to estimate total 2SW equivalent mortalities in North America. The terminal fisheries included coastal, estuarine and river catches of all areas, except Newfoundland and Labrador where only river catches were included and excluding Saint- Pierre and Miquelon. Harvest equivalents within North America peaked at about 362000 in 1976 and have remained below 14000 2SW salmon equivalents since 1999 (Table 4.4.2.1).

In the most recent year, the harvest of cohorts destined to be 2SW salmon in terminal fisheries of North America was $65 \%$ of the total catch. The harvest percentages ranged from 19 to $32 \%$ during 1972 to 1990 and 61 to $89 \%$ during 1993 to 2010 (Table 4.4.2.1). Percentages increased significantly since 1992 with the reduction and closures of the Newfoundland and Labrador commercial mixed-stock fisheries.

### 4.4.3 Gear and effort

## Canada

The 23 areas for which the Department of Fisheries and Oceans (DFO) manages the salmon fisheries are called Salmon Fishing Areas (SFAs); for Québec, the management is delegated to the Ministère des Ressources Naturelles et de la Faune and the fishing areas are designated by Q1 through Q11 (Figure 4.4.3.1). Harvest (fish which are retained) and catches (including harvests and fish caught-and-released in recreational fisheries) are categorized in two size groups: small and large. Small salmon, generally 1SW, in the recreational fisheries refer to salmon less than 63 cm fork length, whereas in commercial fisheries, it refers to salmon less than 2.7 kg whole weight. Large salmon, generally MSW, in recreational fisheries are greater than or equal to 63 cm fork length and in commercial fisheries refer to salmon greater than or equal to 2.7 kg whole weight.

Three groups exploited salmon in Canada in 2010; Aboriginal peoples, residents fishing for food in Labrador, and recreational fishers. There were no commercial fisheries in Canada in 2010.

In 2010, four subsistence fisheries harvested salmonids in Labrador: 1) Nunatsiavut Government (NG) members fishing in the northern Labrador communities of Rigolet, Makkovik, Hopedale, Postville, and Nain and in Lake Melville; 2) Innu Nation members fishing in Natuashish and in Lake Melville from the community of Sheshatshiu; 3) the NunatuKavut Community Council (formerly the Labrador Metis Nation) members fishing in southern Labrador from Fish Cove Point to Cape St Charles and,
4) Labrador residents fishing in Lake Melville and various coastal communities. The NG, Innu, and LMN fisheries were regulated by Aboriginal Fishery Guardians jointly administered by the aboriginal groups and the Department of Fisheries and Oceans (DFO) as well as by DFO Fishery Officers and Guardian staff. The Nunatsiavut Government is directly responsible through the Torngat Fisheries Board for regulating its fishery through its Conservation Officers. The fishing gear is multifilament gillnets of 15 fathoms in length of a stretched mesh size ranging from 3 to 4 inches. Although nets are mainly set in estuarine waters some nets are also set in coastal areas usually within bays. Catch statistics are based on logbook reports.

Most catches (95\%, Figure 2.1.1.3) in North America now take place in rivers or in estuaries. Fisheries are principally managed on a river-by-river basis and, in areas where retention of large salmon is allowed, it is closely controlled. The commercial fisheries are now closed and the remaining coastal food fisheries in Labrador are mainly located close to river mouths and likely harvest few salmon from other than local rivers.

The following management measures were in effect in 2010.

## Aboriginal peoples' food fisheries

In Québec, Aboriginal peoples' food fisheries took place subject to agreements or through permits issued to the bands. There are ten bands with subsistence fisheries in addition to the fishing activities of the Inuit in Ungava (Q11), who fished in estuaries or within rivers. The permits generally stipulate gear, season, and catch limits. Catches in food fisheries have to be reported collectively by each Aboriginal user group. However, if reports are not available, the catches are estimated. In the Maritimes (SFAs 15 to 23), food fishery harvest agreements were signed with several Aboriginal peoples groups (mostly First Nations) in 2010. The signed agreements often included allocations of small and large salmon and the area of fishing was usually inriver or estuaries. Harvests that occurred both within and outside agreements were obtained directly from the Aboriginal peoples. In Labrador (SFAs 1 and 2), food fishery arrangements with the Nunatsiavut Government, the Innu First Nation, and the NunatuKavut Community Council, resulted in fisheries in estuaries and coastal areas. By agreement with First Nations, there were no food fisheries for salmon on the island of Newfoundland in 2010. Harvest by Aboriginal peoples with recreational licences is reported under the recreational harvest categories.

## Resident food fisheries in Labrador

In 2010, a licensed subsistence trout fishery for local residents took place, using gillnets, in Lake Melville (SFA 1) and in estuary and coastal areas of Labrador (SFA 1 and 2). Residents who requested a licence were permitted to retain a bycatch of four salmon of any size while fishing for trout and charr; four salmon tags accompanied each licence. When the bycatch of four salmon was caught the resident fishers were required to remove their net from the water. All licensees were requested to complete logbooks. DFO is responsible for regulating the Resident Fishery.

## Recreational fisheries

Licences are required for all persons fishing recreationally for Atlantic salmon. Gear is restricted to fly fishing and there are daily/seasonal bag limits (Figure 4.4.3.2). Recreational fisheries management in 2010 varied by area and large portions of the southern areas remained closed to all directed salmon fisheries. Except in Québec and

Labrador (SFA 1 and some rivers of SFA 2), only small salmon could be retained in the recreational fisheries.

## USA

There were no recreational or commercial fisheries for Atlantic salmon in the USA in 2010.

## France (Islands of Saint-Pierre and Miquelon)

Nine professional and 57 recreational gillnet licences were issued in 2010, an increase of one professional licence and seven recreational licences from 2009. Professional licences have a maximum authorization of three nets of 360 metres maximum length whereas the recreational licence is restricted to one net of 180 metres. The time-series of available data are in Table 4.4.3.1.

### 4.4.4 Catches in 2010

## Canada

The provisional harvest of salmon in 2010 by all users was 146 t , about $16 \%$ higher than the 2009 harvest of 126 t (Table 2.1.1.1; Figure 4.4.4.1). The 2010 harvest was 54116 small salmon and 10988 large salmon, $26 \%$ more small salmon and $2 \%$ less large salmon compared with 2009. The dramatic decline in harvested tonnage since 1988 is in large part the result of the reductions in commercial fisheries effort; the closure of the insular Newfoundland commercial fishery in 1992, the closure of the Labrador commercial fishery in 1998 and the closure of the Québec commercial fishery in 2000.

## Aboriginal peoples' food fisheries

The total harvest by Aboriginal people in 2010 was 59.3 t (Table 4.4.4.1). Harvests (by weight) increased by $16 \%$ from 2009.

## Residents fishing for food in Labrador

The estimated catch for the fishery in 2010 was 2.3 t . This represents approximately 1000 fish, $25 \%$ of which were large.

## Recreational fisheries

Harvest in recreational fisheries in 2010 totalled 44073 small and large salmon (approximately 84 t ), was $21 \%$ above the 2009 harvest level, but remains at low levels similar to the previous decade (Figure 4.4.4.2). The small salmon harvest of 40861 fish was $24 \%$ higher than the 2009 harvest. The large salmon harvest of 3212 fish was $5 \%$ below the 2009 harvest. The small salmon size group has contributed $88 \%$ on average of the total recreational harvests since the imposition of catch-and-release recreational fisheries in the Maritimes and insular Newfoundland (SFA 3 to 14B, 15 to 23) in 1984. In 2010, approximately 58300 salmon (about 35600 small and 22700 large) were caught and released (Table 4.4.4.2), representing about $62 \%$ of the total number caught (including retained fish). There is some mortality on these released fish, which is accounted for in the spawner estimates.

Recreational catch statistics for Atlantic salmon are not collected regularly in Canada and there is no mechanism in place that requires anglers to report their catch statistics, except in Québec. The last recreational angler survey for New Brunswick was
conducted in 1997 and the catch rates for the Miramichi from that survey have been used to estimate catches (both harvest and catch and release) for all subsequent years. The reliability of recreational catch statistics could be improved in all areas of Canada.

## Commercial fisheries

All commercial fisheries for Atlantic salmon remained closed in Canada in 2010 and the catch therefore was zero.

## Unreported catches

The unreported catch estimate for Canada is incomplete. The reports received from three of the four administrative regions totals 15 t in 2010. A large part of this unreported catch is illegal fisheries directed at salmon.

## USA

There are no commercial or recreational fisheries for Atlantic salmon in USA and the catch therefore was zero. Unreported catches in the USA were estimated to be 0 t . Illegal fishing activities on salmon were noted in 2010.

## France (Islands of Saint-Pierre and Miquelon)

A total harvest of 2.8 t was reported in the professional and recreational fisheries in 2010, down from the higher values of about 3.5 t in 2008 and 2009 (Table 4.4.3.1).

There are no unreported catch estimates.

### 4.4.5 Origin and composition of catches

In the past, salmon from both Canada and the USA were taken in the commercial fisheries of eastern Canada. The Aboriginal Peoples' and resident food fisheries that occur in Labrador may intercept salmon from other areas of North America; however, in 2009 and 2010, there were no salmon tagged in other areas and reported from the food fisheries. Also none of the salmon sampled during the Food Fishery Sampling Program in those years were tagged or marked. No tags were reported from the fishery in Saint-Pierre and Miquelon.

## Results of sampling programme for Labrador subsistence fisheries

A sampling programme of the subsistence fisheries in Labrador continued in 2010, conducted by the Labrador Metis Nation, aboriginal guardians, and Conservation Officers of the Nunatsiavut Government. Landed fish were sampled opportunistically for fork length, weighed (gutted weight or whole weight if available) and where possible the sex was determined. Scales were taken for subsequent age analysis. Fish were also examined for the presence of external tags, brands or elastomer marks, and adipose fin clips.

In 2010, a total of 222 samples were collected from the subsistence fisheries, 113 from northern Labrador (SFA 1) and 109 samples from southern Labrador (SFA 2, Figure 4.4.5.1). Based on the interpretation of the scale samples, $73 \%$ of all the samples taken were 1 SW salmon, $16 \%$ were 2 SW, and $10 \%$ were previously spawned salmon. Small and large salmon based on a 2.7 kg cut off, similar to that used in the Aboriginal fishery, indicated small salmon were $92 \% 1 \mathrm{SW}, 2 \% 2 \mathrm{SW}$ and $6 \%$ previously spawned salmon and large salmon were $27 \%$ 1SW, $53 \%$ 2SW and $20 \%$ previously spawned
salmon. These are similar to the age structure by size groups from previous years ICES 2009a; ICES 2010b).

The river ages (Figure 4.4.5.2) of samples collected from the subsistence fisheries were compared with ages from scales (1946 samples from Northern Labrador and 975 in Southern Labrador) obtained from assessment facilities in 2000 to 2005. As noted in previous years, there was a difference in-river age distribution of adults from subsistence fisheries compared with returns to rivers in Northern Labrador (Chisquared=24.9, $\mathrm{P}=<0.0001$ ) with larger proportions of river age 3 and smaller proportions of river age 5 salmon in the subsistence fisheries compared with the assessment facilities. The same differences in relative proportions of river age 3 and river age 5 were also noted for Southern Labrador in 2010 (Chi-squared=11.5, $\mathrm{P}=0.075$ ). The larger proportion of river age 3 smolts was also noted for the Lake Melville samples (Figure 4.4.5.3), but no samples are available from in-river monitoring to assess whether salmon from these populations have similar smolt age distributions to those populations in the coastal rivers of northern Labrador.

There were no river age 1 or 2 fish in the samples from the Northern Labrador fishery (SFA 1) and a low percentage of river age 1 and 2 salmon in the samples from Southern Labrador (Figure 4.4.5.2). The very low percentages of river age 1 and age 2 and the high percentage of river ages 4 to 7 salmon in the catches of 2010, as in previous years, suggests that very few salmon from the most southern stocks of North America (USA, Scotia-Fundy) are exploited in these fisheries.

The Working Group noted that the sampling programme conducted in 2010 provided biological characteristics of the harvest and that the information may be useful for updating parameters used in the Run Reconstruction Model for North America. As well it provides material (tissue samples from scales) to assess the origin of salmon in this fishery.

## Results of sampling programme for Saint-Pierre and Miquelon

In 2010, biological characteristics (length, weight) were obtained from 57 salmon in the fishery and tissue samples (adipose fin tissue) were collected from 51 of these sampled fish. The tissue samples were analysed by a laboratory in France for 15 mi crosatellite markers commonly used for Atlantic salmon. The genetic characterization of the samples was compared with baseline populations comprised of four Canadian populations (Tobique River New Brunswick and the Sainte Marguerite, Sainte Anne, and Malbaie rivers from Québec), two populations from the USA (Narraguagus and Penobscot) and 28 populations from the NEAC area. The Working Group noted that the baseline was absent of any populations from Canadian rivers adjacent to St Pierre and Miquelon.

Of the 57 salmon sampled, 32 were of fork length less than 63 cm (range from 47 to 59 cm ). The large salmon group ( $>=63 \mathrm{~cm}$ ) ranged from 67 to 84 cm fork length, with the most abundant fish in the 71 to 78 cm fork length sizes.

None of the fish sampled were genetically identified to the NEAC stocks. With the limited baselines available, three of the fish were closest to the USA characteristics, and the remaining 47 to the Canadian rivers. This is similar to the analyses from the 2004 fishery which had also indicated a predominance of Canadian origin salmon in the catches (ICES 2006).

The Working Group welcomed the efforts to sample the catches at Saint-Pierre and Miquelon to estimate stock contributions to the harvest and recommend that sam-
pling be continued in future. However, the Working Group identified a number of issues with the sampling programme that if corrected, would greatly increase the value of data. First, it would be useful to identify the fishing sites and collection dates where the samples originated from to evaluate if the results are representative of the harvest at both spatial and temporal scales. Second, the baseline of Canadian and USA populations used was very small. Much more extensive baselines of Canadian and USA populations exist, including samples from rivers in Newfoundland. Members of the Working Group offered to run additional analyses on the samples to assess at a finer spatial scale the origin of the fish in the catches. Third, reporting on additional quality checks to demonstrate if DNA extraction, amplification and scoring efforts were effective and that no alleles were dropped would be useful information to present.

The issues identified above regarding stock origin identification of the fisheries at Labrador and Saint-Pierre and Miquelon should be resolved. Genetic analysis techniques offer the opportunity to identify the origin of harvested individuals at varying levels of origin and can provide the information necessary to evaluate the effect that these mixed-stock fisheries have on the contributing populations. Appropriate baselines that represent all populations subjected to the fishery are required to support these analyses.

The Working Group recommends that sampling of the Labrador and Saint-Pierre and Miquelon fisheries be continued and expanded (i.e. sample size, geographic coverage, tissue samples, seasonal distribution of the samples) if possible in 2011 and future years. As well, scale samples from in-river fisheries (recreational) in Labrador, should be collected to determine the river age distributions of the salmon populations not currently being monitored by the limited (three to four) assessment facilities.

### 4.4.6 Exploitation rates

## Canada

In the Newfoundland recreational fishery, exploitation rates for retained small salmon ranged from a high of $12 \%$ on Torrent River to a low of $6 \%$ on Terra Nova River. Overall, exploitation rates of small salmon in these rivers declined from $30 \%$ in 1986 to approximately $10 \%$ in 2010 which is one of the lowest rates of the past 25 years. In Sand Hill River, Labrador, exploitation rate on small salmon was $5 \%$ and no large salmon were reported as retained in 2010

In Québec, the 2010 total fishing exploitation rate was around $17 \%$; slightly lower than the average of the five previous years. Native peoples' fishing exploitation rate was $5 \%$ of the total return. Recreational fishing exploitation rate was $12 \%$ on the total run, $17 \%$ for the small and $7 \%$ for the large salmon, representing a decrease from the previous five year average of $18 \%$ for small salmon and $9 \%$ for large salmon.

## USA

There was no exploitation of USA salmon in home waters, and no tagged salmon of USA origin were reported in Canadian fisheries in 2010.

## Exploitation trends for North American salmon fisheries

Annual exploitation rates of small salmon (mostly 1SW) and large salmon (mostly MSW) in North America for the 1971 to 2010 time period were calculated by dividing annual harvests in all North American fisheries by annual estimates of the returns to

North America prior to any fisheries in North America. The fisheries included coastal, estuarine and river fisheries in all areas, as well as the commercial fisheries of Newfoundland and Labrador which harvested salmon from all regions in North America.

Exploitation rates of both small and large salmon fluctuated annually but remained relatively steady until 1984 when exploitation of large salmon declined sharply with the introduction of the non-retention of large salmon in angling fisheries and reductions in commercial fisheries (Figure 4.4.6.1). Exploitation of small salmon declined steeply in North America with the closure of the Newfoundland commercial fishery in 1992. Declines continued in the 1990s with continuing management controls in all fisheries to reduce exploitation. In the last few years, exploitation rates on small salmon and large salmon have remained at the lowest in the time-series, average of $15 \%$ for both small salmon and large salmon over the past ten years. However, exploitation rates across regions within North America are highly variable.

### 4.5 Elaboration on status of stocks

To date, 1082 Atlantic salmon rivers have been identified in eastern Canada and 21 rivers in eastern USA, where salmon are or were present within the last half century. The upward revision to that previously reported by ICES (2008a) is attributable to a number of factors detailed below. Assessments were reported for 71 of these rivers in 2010.

Canada has documented the current and best information available, based on common criteria, on rivers with anadromous Atlantic salmon in eastern Canada. Recently, the DFO regions and the province of Québec contributed information in support of the development of a status report of Atlantic salmon by COSEWIC (Committee on the Status of Endangered Wildlife in Canada). A list of rivers with Atlantic salmon was compiled with some accompanying descriptions of those rivers, the details varying among rivers and among regions (Breau et al., 2009; Cairns et al., 2010; Cameron et al., 2009; Chaput et al., 2010; Gibson and Bowlby, 2009; Gibson et al., 2010; Jones et al., 2010; MRNF 2010; Reddin et al., 2010).

A river was defined as a fluvial system flowing directly into tidal water (Reddin et al., 2010). Under this definition, some previously considered salmon rivers were deleted while some rivers were subdivided into several rivers (i.e. the Miramichi River in New Brunswick is subdivided into six rivers based on the location of river mouth in tidal waters). This database was used to update NASCO's North Atlantic-wide database of rivers with Atlantic salmon.

The updated database for Canada has entries for 1082 rivers within the five provinces of eastern Canada.

| Province | Number of rivers |  |
| :--- | :---: | :---: |
| Newfoundland and Labrador |  | 581 |
| Newfoundland | 271 |  |
| Labrador | 310 |  |
| Québec |  | 113 |
| New Brunswick | 118 |  |
| Prince Edward Island | 59 |  |
| Nova Scotia | 211 |  |
| Canada Total | 1082 |  |

Conservation requirements in terms of eggs have been defined for $45 \%$ (485) of the 1082 rivers in the database. For rivers with conservation requirements, over $59 \%$ of them have conservation requirements less than 1 million eggs, which translates to roughly 200 to 300 spawners depending upon life-history type. Collectively, $91 \%$ of the rivers have conservation requirements less than five million eggs.

|  |  | $\%$ of rivers <br> with defined <br> requirements |  |
| :---: | :---: | :---: | :---: |
| Conservation requirement (million eggs) | Frequency | 285 | $59 \%$ |
| $>1$ | 157 | $32 \%$ |  |
| $>1,<=5$ | 22 | $5 \%$ |  |
| Canada Total | $>5,<=10$ | 16 | $3 \%$ |

A status category was assigned to $68 \%$ of the rivers in the database (Table 4.5.1). The largest number of rivers with the status assessed as "Unknown" is from Labrador ( $16 \%$ of region total) (Figure 4.5.1). A total of $49 \%$ of the assessed rivers were classified as "Not Threatened with loss" and $49 \%$ were classified as "Threatened with loss" (30\%) or "Lost" (19\%). Every region except Labrador has a number of rivers for which the populations are considered to be "Threatened with loss". The province of Nova Scotia has the highest percent of rivers classified as "Lost" (47\%). The losses have occurred primarily in the southern uplands portion of the Atlantic coast of Nova Scotia (Gibson et al., 2010). Only a handful of rivers were classified as either "Maintained", "Restored" or "Not Present but potential".

### 4.5.1 Smolt and juvenile abundance

## Canada

Wild smolt production was estimated in 12 rivers in 2010. Of these, 12 rivers have at least eight years of information and nine have data for over 15 years (Figure 4.5.1.1).

In 2010, smolt production increased ( $>110 \%$ ) from 2009 in six rivers, decreased ( $<90 \%$ ) in four rivers and remained unchanged in two rivers. The relative smolt production, scaled to the size of the river using the conservation egg requirements, was highest in the rivers of Québec and lowest in the southern rivers of the Scotia Fundy region (Figure 4.5.1.1). For most of the 12 rivers there has been no significant linear trend in smolt production ( $\mathrm{P}>0.05$ ) over the available time-series with the exception of: 1 ) significant decreases in de la Trinité and St Jean (Québec) and 2) significant increases in Southwest Miramichi (Gulf) and Western Arm Brook (WAB) (Newfoundland).

## USA

Wild salmon smolt production has been estimated on the Narraguagus River for 14 years (Figure 4.5.1.1). Smolt production in 2010 was $84 \%$ above that of 2009, but the trend since 1997 remains negative ( $\mathrm{P}<0.05$ ).

### 4.5.2 Estimates of total adult abundance by geographic area

Returns of small (1SW), large, and 2 SW salmon (a subset of large) to each region (Figures 4.5.2.1, 4.5.2.2 and 4.5.2.3; and Annex 6) were originally estimated by the methods and variables developed by Rago et al. (1993) and reported by ICES (1993). At the 2010 Working Group meeting there were some changes to the input variables used. The returns for individual river systems and management areas for both sea age groups were derived from a variety of methods. These methods included counts of salmon at monitoring facilities, population estimates from mark-recapture studies, and applying angling and commercial catch statistics, angling exploitation rates, and measurements of freshwater habitat. The 2 SW component of the large returns was determined using the sea age composition of one or more indicator stocks.

Returns are the number of salmon that returned to the geographic region, including fish caught by homewater commercial fisheries, except in the case of the Newfoundland and Labrador regions where returns do not include landings in commercial and food fisheries. This avoided double counting fish because commercial catches in Newfoundland and Labrador and food fisheries in Labrador were added to the sum of regional returns to create the PFA of North American salmon.

Total returns of salmon to USA rivers are the sum of trap catches and redd based estimates.

## Canada

## Labrador

The median of the estimated returns of small salmon in 2010 to Labrador (91 870) was $3 \%$ higher than the previous year and $50 \%$ lower than the previous 5 -year mean (184 520, Figure 4.5.2.1). The median of the estimated 2SW returns in 2010 to Labrador (8961) was $65 \%$ lower than the previous year and $47 \%$ lower than the previous 5 year mean (16 894, Figure 4.5.2.3).

Labrador regional estimates are generated from data collected at four counting facilities (one in SFA 1 and three in SFA 2, Figure 4.4.3.1), but only three facilities operated in 2010 (two in SFA 2). The production area in SFA 1 is approximately equal to the production area in SFA 2. The current method to estimate Labrador returns assumes that the total returns to the northern area are represented by returns at the single monitoring facility in SFA 1 and returns in the southerly areas (SFA2 and 14b) are represented by returns at the monitoring facilities in SFA 2. Further work is needed to understand the best use of these data in describing stock status and the Working Group recommends that additional monitoring data be considered in Labrador to better estimate salmon returns in that region.

## Newfoundland

The median of the estimated returns of small salmon in 2010 to Newfoundland (229 800) was $3 \%$ higher than the previous year and $6 \%$ higher than the previous 5 year mean (217 620, Figure 4.5.2.1). The median (2207) of the estimated 2SW returns in 2010 to Newfoundland was $52 \%$ lower than the previous year and $51 \%$ lower than the previous 5 -year mean (4483, Figure 4.5.2.3).

## Québec

The median of the estimated returns of small salmon in 2010 to Québec (28 130) was $27 \%$ higher than the previous year and $3 \%$ higher than the previous 5 -year mean
(27 828, Figure 4.5.2.1). The median of the estimated returns of 2SW in 2010 to Québec (29 450) was $7 \%$ higher than the previous year and $10 \%$ higher than the previous 5 year mean (26 750, Figure 4.5.2.3).

## Gulf of St Lawrence

The median of the estimated returns of small salmon in 2010 to the Gulf ( 74 120) was $190 \%$ higher than the previous year and $60 \%$ higher than the previous 5 -year mean ( 46448 , Figure 4.5.2.1). The median of the estimate of 2 SW returns in 2010 to the Gulf (18780) was $20 \%$ lower than the previous year and $14 \%$ lower than the previous 5 year mean (21 766, Figure 4.5.2.3).

## Scotia-Fundy

The median of the estimated returns of small salmon in 2010 to Scotia-Fundy (14 870) was $251 \%$ higher than the previous year and $65 \%$ higher than the previous 5 -year mean (9020, Figure 4.5.2.1). The median of the estimated 2SW returns in 2010 to Sco-tia-Fundy (2013) was $25 \%$ lower than the previous year and $11 \%$ lower than the previous 5 -year mean (2271, Figure 4.5.2.3).

The model currently being used to extrapolate for the Nova Scotia Atlantic coast assessed rivers to total abundance (both returns and spawners) within SFAs 19-21 is likely leading to an overestimation of this portion of the regional abundance. The model is based on the assumption that the LaHave River salmon count is a representative index of this portion, an assumption that is likely invalid (ICES, 2010b). This issue is expected to have very little effect on the advice provided on overall status of salmon in North America, but does have implications for regional management.

## USA

The estimated returns of small salmon in 2010 to USA (525) were $118 \%$ higher than the previous year and $24 \%$ higher than the previous 5 -year mean (424, Figure 4.5.2.1). The estimated returns of 2SW in 2010 to USA (1078) were $48 \%$ lower than the previous year and $21 \%$ lower than the previous 5-year mean (1359, Figure 4.5.2.3).

### 4.5.3 Estimates of spawning escapements

Updated estimates for small, large and 2SW spawners (1971 to 2010) were derived for the six geographic regions. A comparison between the numbers of small and large returns and spawners is presented in Figures 4.5.2.1 and 4.5.2.2. A comparison between the numbers of 2 SW returns, spawners, and CLs is presented in Figure 4.5.2.3.

## Canada

## Labrador

The median of the estimated numbers of 2SW spawners (8765) was $65 \%$ lower than the previous year and $47 \%$ lower than the previous 5-year mean (16 654). The 2010 2SW spawners achieved $25 \%$ of the 2 SW CL for Labrador (Figure 4.5.2.3). The 2SW spawner limit has not been exceeded during the time-series. The median of the estimated numbers of small spawners ( 90090 ) was $2 \%$ higher than the previous year and $51 \%$ lower than the previous 5-year mean (182 270, Figure 4.5.2.1).

## Newfoundland

The median of the estimated numbers of 2SW spawners (2126) was $53 \%$ lower than the previous year and $52 \%$ lower than the previous 5 -year mean (4405). The 2010 2SW spawners achieved $53 \%$ of the 2SW CL for Newfoundland. The 2SW CL has been met or exceeded in four out of the last ten years (Figure 4.5.2.3). The median of the estimated number of small spawners (203000) was 3\% higher than the previous year and $5 \%$ higher than the previous 5 -year mean ( 194060 , Figure 4.5.2.1). There was a general increase in both 2SW and 1SW spawners during the period 1992 to 1996 and 1998 to 2000, which is consistent with the closure of the commercial fisheries in Newfoundland.

## Québec

The median of the estimated numbers of 2SW spawners (23580) was $13 \%$ higher than the previous year and $19 \%$ higher than the previous 5 -year mean (19 894). The 2010 2SW spawners achieved $77 \%$ of the 2 SW CL for Québec (Figure 4.5.2.3). The median of the estimated number of small spawners (205000) was $27 \%$ higher than the previous year and $3 \%$ higher than the previous 5 -year mean (199 000, Figure 4.5.2.1).

## Gulf of St Lawrence

The median of the estimated numbers of 2SW spawners (17990) was $20 \%$ lower than the previous year and $14 \%$ lower than the previous 5 -year mean ( 20900 ). The 2010 2SW spawners achieved $61 \%$ of the 2 SW CL for the Gulf (Figure 4.5.2.3). The median of the estimated number of small spawners (47980) was $206 \%$ higher than the previous year and $61 \%$ higher than the previous 5 -year mean ( 29738 , Figure 4.5.2.1).

## Scotia-Fundy

The median of the estimated numbers of 2 SW spawners (1883) was $26 \%$ lower than the previous year and 13\% lower than the previous 5-year mean (2153). The 2010 2SW spawners achieved $13 \%$ of the 2SW CL for Scotia-Fundy (Figure 4.5.2.3). The median of the estimated number of small spawners (14780) was $263 \%$ higher than the previous year and $68 \%$ higher than the previous 5 -year mean (8812, Figure 4.5.2.1). As was the case with returns, these values may be overestimates (see Section 4.5.2).

## USA

The estimated numbers of 2SW spawners (1482) was $35 \%$ lower than the previous year and $16 \%$ lower than the previous 5 -year mean (1759). The 2010 2SW spawners achieved $5 \%$ of the 2SW CL for USA (Figure 4.5.2.3). The estimated number of small spawners (525) was $118 \%$ higher than the previous year and $24 \%$ higher than the previous 5 -year mean (424, Figure 4.5.2.1).

### 4.5.4 Egg depositions in 2010

Egg depositions by all sea ages combined in 2010 exceeded or equalled the riverspecific CLs in 31 of the 71 assessed rivers (44\%) and were less than $50 \%$ of CLs in 19 rivers ( $37 \%$; Figure 4.5.4.1).

- In Labrador, none of the three assessed rivers exceeded their CLs (only one of three met the CLs in 2009) but none of the assessed rivers had egg depositions that were less than $50 \%$ of their CLs.
- In Newfoundland, $53 \%$ (eight of 15 ) of the rivers assessed met or exceeded the CLs and only one location (upper Exploits River) had egg depositions that were less than $50 \%$ of the CL.
- For the three assessed rivers in the Gulf, two exceeded their CLs and the third was at $80 \%$ of the CL.
- In Québec, $57 \%$ (20 of 35) of assessed rivers had egg depositions that equalled or exceeded their CLs. Six rivers were below $50 \%$ of their CLs.
- Large deficiencies in egg depositions were noted in the Bay of Fundy and Atlantic coast of Nova Scotia (SFA 19-23) where the CL was met in only one river and six of the nine assessed rivers ( $89 \%$ ) had egg depositions that were less than $50 \%$ of their CLs. Abundance in most rivers in this region is low (four of the nine assessed rivers were below $25 \%$ of their CLs).
- Large deficiencies in egg depositions were noted in the USA, none of the six assessed rivers met their CLs. On an individual river basis, the Penobscot River met $13 \%$ (compared with $26 \%$ in 2009) of its spawner requirement while the other five USA rivers were at 0.0 to $9.0 \%$ of their CL.

### 4.5.5 Marine survival rates

In 2010, return rate data were available from eleven wild and three hatchery populations from rivers distributed among Newfoundland, Québec, Scotia-Fundy, and USA. In the eleven wild stocks with available data, return rates to 1SW fish in 2010 increased relative to 2009 ( $4 \%$ to 199\%). Larger increases were also noted in 1SW return rates for hatchery stocks ( $>800 \%$ ). However, on four rivers in Newfoundland and one in USA, return rates to 1SW fish for wild populations were still 11 to $43 \%$ below 2008 levels.

Return rates in 2010 for wild 2SW salmon from the 2008 smolt class increased ( $44 \%$ to $284 \%$ ) relative to the 2007 smolt class in four of six rivers with available data. The exceptions were the Southwest Miramichi ( $12.5 \%$ decrease) and the Narraguagus ( $68 \%$ decrease). In contrast to generally higher return rates of wild 2 SW salmon from the 2008 smolt class, returns rates for 2 SW salmon decreased for all three hatchery stocks monitored, one in Canada ( $6 \%$ ) and two in the USA (median 46\%). Return rates of wild stocks exceeded those of hatchery stocks.

Time-series analyses of return rates to 1SW and 2SW adults by area (Figure 4.5.5.1) and analysis of the rates of change for individual rivers (Figures 4.5.5.2) provide insights into spatial and temporal changes in marine survival of wild and hatchery stocks.

## Temporal trends

- 1 SW return rates in 2010 to all areas and rivers were higher than in 2009 for both wild and hatchery stocks.
- Return rates of 2SW salmon increased from 2009 for four of six wild stocks, and decreased for the three hatchery populations.
- Mean 2006 to 2010 return rate for 1SW wild salmon smolts in Newfoundland were similar to the mean 2001 to 2005 rate.
- Mean 2006 to 2010 return rate for 1SW wild and hatchery salmon smolts across the North American Commission were higher than the mean 2001 to 2005 rate for all but two of the ten predominantly MSW rivers monitored.
- Mean 2006 to 2010 return rate for 2SW wild and hatchery salmon smolts across the North American Commission were higher than the mean 2001 to 2005 rate for six of the ten predominantly MSW rivers monitored.

## Spatial trends

- 1 SW return rates of wild smolts to Newfoundland, although varying annually, have no significant temporal trend over the period 1970 to 2010 ( $\mathrm{p}>0.05$ ).
- 1 SW and 2SW return rates of wild smolts to the Gulf and Québec have both declined $(\mathrm{p}<0.05)$ over the periods for which data were available.
- 1 SW and 2 SW return rates of wild smolts to the Scotia-Fundy and USA, although varying annually, have no significant temporal trend over the period 1996 to 2010 ( $\mathrm{p}>0.05$ ).
- In Scotia-Fundy and USA, hatchery smolt return rates to 2SW salmon have decreased over the period 1970 to 2010 ( $\mathrm{p}<0.05$ ). 1SW return rates for Sco-tia-Fundy stocks also declined for the period ( $\mathrm{p}<0.05$ ), while for USA there has been no significant trend ( $p>0.05$ ).
- 1 SW return rates in predominately MSW salmon stocks in USA and Québec are lower than those in predominantly 1 SW salmon stocks of Newfoundland.
- 1 SW return rates in predominately MSW salmon stocks in Gulf and ScotiaFundy are within the range of those in predominantly 1SW salmon stocks of Newfoundland.
- 1 SW return rates in predominately MSW salmon stocks of the ScotiaFundy, Québec, and Gulf exceed those of 2 SW salmon within a smolt cohort.
- 2 SW return rates in predominately MSW salmon stocks in USA exceed those of 1SW salmon within a smolt cohort.

### 4.5.6 Pre-fisheries abundance

### 4.5.6.1 North American run-reconstruction model

The run-reconstruction model developed by Rago et al. (1993) and described in previous Working Group reports (ICES 2008a, 2009a) and in the primary literature (Chaput et al. 2005) was used to estimate returns and spawners by size (small salmon, large salmon) and sea age group ( 2 SW salmon) to the six geographic regions of NAC. The input data were similar in structure to the data used previously by the Working Group (ICES, 2009a). Following on the recommendations from ICES (2008a), the runreconstruction model for 2009 was developed using Monte Carlo simulation (OpenBUGS) similar to the approach applied for the NEAC area (Section 3.8.9). Updates to estimates of returns and spawners to regions were provided for 2009 and preliminary values were provided for 2010 (Annex 6).

The full set of data inputs and the summary output tables of catches, returns and spawners by sea age or size group are provided in Annex 6.

### 4.5.6.2 Non-maturing ISW salmon

The non-maturing component of 1 SW fish, destined to be $2 S W$ returns (excluding 3SW and previous spawners) is represented by the pre-fishery abundance estimator for year i designated as PFANAC1SW. This annual pre-fishery abundance is the es-
timated number of salmon in West Greenland prior to the start of the fishery on August 1 st. As the pre-fishery abundance estimates for potential $2 S W$ salmon requires estimates of returns to rivers, the most recent year for which an estimate of PFA is available is 2009. This is because pre-fishery abundance estimates for 2010 require 2SW returns to rivers in North America in 2011. The medians derived from Monte Carlo simulations for 2 SW salmon by region and for NAC overall are shown in Figure 4.5.2.3. The estimated abundance of 2SW to rivers for NAC in 2010 was about 62470 fish ( $95 \%$ C.I. range 55940 to 69050 ). The median estimate for 2010 is $12 \%$ lower than the estimated average abundance of the previous ten years (2000 to 2009), is the second lowest in the 40 year time-series (1971 to 2010) and has remained low over the past decade relative to historical estimates.

The PFA estimates accounting for returns to rivers, fisheries at sea in North America, fisheries at West Greenland, and corrected for natural mortality are shown in Figure 4.5.6.2.1. The median of the estimates of non-maturing 1SW salmon in 2009 was 101200 fish ( $95 \%$ C.I. range 88530 to 115500 ). This value is $8 \%$ lower than the previous 10-year average (1999 to 2008). The estimated non-maturing 1SW salmon in 2009 is the third lowest in the 39 year time-series (1971 to 2009).

### 4.5.6.3 Maturing 1 SW salmon

Maturing 1SW salmon are in some areas (particularly Newfoundland) a major component of salmon stocks, and their abundance when combined with that of the 2SW age group provides an index of the majority of an entire smolt cohort.

The medians of the region-specific estimates of returns of the 1SW maturing component to rivers of NAC are summarized in Figure 4.5.2.1. The NAC total maturing 1SW salmon abundance has oscillated between 250000 and 574000 over the period 1971 to 2010. Estimated abundance in 2010 (439 300) was $21 \%$ above the previous year's estimate (364 500), but 9\% below the previous 5-year mean (2005 to 2009) of 485320 . Increases were realized across all regions with large increases realized in the Gulf, Scotia Fundy and USA (118 to $251 \%$ ). Returns in Labrador were $50 \%$ lower than the previous 5-year mean. Returns of maturing 1SW salmon have general increased over the time-series for the NAC; mainly a result of the commercial fishery closures in Canadian and increased returns over time to Labrador and Newfoundland.

The reconstructed distributions of the abundance of the 1SW maturing cohort of North American origin are shown in Figure 4.5.6.2.1. The PFA of the maturing component in 2010 was estimated as 463500 fish, $17 \%$ above the 2009 value. Maximum abundance of the maturing cohort was estimated at over 910000 fish in 1981 and recent estimates remain among the lowest in the time-series (1971 to 2010).

### 4.5.6.4 Total 1 SW recruits (maturing and non-maturing)

The pre-fishery abundance of 1SW maturing salmon for the 1971 to 2010 and 1SW non-maturing salmon from North America for 1971 to 2009 were combined to give total recruits of 1 SW salmon (Figure 4.5.6.2.1). The overall abundance of the 1SW cohort, estimated in 2009, was 486100 fish, $34 \%$ lower than estimated in 2008 and the 3 rd lowest in the 39 year time-series (1971 to 2009). The abundance of the 1SW cohort has declined by $71 \%$ over the time-series (1971 to 2009) from a peak of 1700000 in 1975.

### 4.6 Summary on status of stocks

In 2010, the midpoints of the spawner abundance estimates for six geographic areas indicated that all areas were below their CLs for 2 SW salmon and are suffering reduced reproductive capacity.

Estimates of pre-fishery abundance suggest continued low abundance of North American adult salmon. The total population of 1SW and 2SW Atlantic salmon in the Northwest Atlantic has oscillated around a generally declining trend since the 1970s with a period of persistent low abundance since the early 1990s. During 1993 to 2008, the total population of 1 SW and 2 SW Atlantic salmon was about 600000 fish, about half of the average abundance during 1972 to 1990. The maturing 1SW salmon in 2010 has increased $17 \%$ from the 2009 value and remains among the low end of the timeseries. The non-maturing estimate decreased by $25 \%$ over the 2008 estimate and is also among the lowest in the time-series.

The returns of 2SW fish in 2010 decreased from 2009 in Labrador (65\%), Newfoundland ( $51 \%$ ), Gulf ( $14 \%$ ), Scotia-Fundy ( $11 \%$ ) and USA ( $21 \%$ ), and increased in Québec (7\%). Returns in 2010 of 1SW salmon relative to 2009 increased in all areas with a range of $3 \%$ in Labrador and Newfoundland to $251 \%$ in Scotia-Fundy. Returns were also above ( 3 to $65 \%$ ) the previous 5 -year mean ( 2005 to 2009) in all regions except for Labrador (50\% decrease).

The rank of the estimated returns in the 1971 to 2010 time-series and the proportions of the 2SW CL achieved in 2010 for six regions in North America are shown below:

| Region | Rank of 2010 returns in 1971 to 2010, ( $40=$ LOWEST) |  | Rank of 2010 returns in 2001 to 2010 ( $10=$ LOWEST) |  | Median estimate of 2SW spawners as percentage of Conservation Limit (\%) |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1SW | 2SW | 1SW | 2SW |  |
| Labrador | 15 | 29 | 8 | 10 | 25 |
| Newfoundland | 5 | 37 | 3 | 10 | 53 |
| Québec | 22 | 31 | 5 | 3 | 77 |
| Gulf | 16 | 34 | 2 | 8 | 61 |
| Scotia-Fundy | 28 | 37 | 2 | 7 | 8 |
| USA | 12 | 33 | 2 | 5 | 5 |

Egg depositions by all sea ages combined in 2010 exceeded or equalled the riverspecific CLs in 31 of the 71 assessed rivers ( $44 \%$ ) and were less than $50 \%$ of CLs in 19 other rivers (37\%, Figure 4.5.4.1).

For insular Newfoundland smolt production has increased in two of four monitored rivers (1970 to 2010). Over the same period return rates of these smolts to 1SW salmon, although varying annually, have no significant temporal trend. Returns to Newfoundland, where rivers are primarily 1SW stocks, have increased over the period, reflecting that populations are responding to increasing spawner escapement.

Smolt production has declined since the mid to late 1980s in two monitored Québec rivers with data extending to 2010. Return rates of these smolts to 1SW and 2SW salmon both declined over the same period. As a consequence, over the period 1980 to 2010, returns of 1SW and 2SW to Québec declined from above CL to below CL.

For the Gulf smolt production has increased in one of three monitored rivers from the late 1990s to 2010, and over the same period return rates of these smolts to 1SW and

2SW salmon have both declined. Declining return rates resulted in declining 2SW returns and spawners over the period, with the CL currently not being met.

Smolt production has remained relatively constant since the late 1990s in two monitored Scotia-Fundy rivers with data extending to 2010. Similarly, return rates of these smolts to 1SW and 2SW salmon, although varying annually, are low and have no significant temporal trend. Low smolt output and return rates resulted in declining returns and spawners of 1SW and 2SW to Scotia-Fundy over the period.

Smolt production on the Narraguagus River in USA declined over the period 1997 to 2010; however survival of wild smolts to 1SW and 2SW salmon, although varying annually, has no significant temporal trend. For hatchery smolt, a large component of smolt production in USA, return rates to 2SW salmon have declined from 1970 to 2010. Declining wild smolt output and declining return rates to 2 SW salmon for hatchery smolts resulted in declining returns and spawners of 1SW and 2SW since the late 1980s.

Based on region-specific CL for 2 SW all salmon stocks are suffering reduced reproductive capacity, with particularly large deficits in the Bay of Fundy, Atlantic coast and USA. Despite major changes in fisheries management 18 to 25 years ago and increasingly more restrictive fisheries measures since, returns in these regions have remained near historical lows and many populations are currently threatened with extirpation. In 2010, the estimated PFA of 1SW maturing salmon ranks 28th out of the 40-year time-series and the estimated PFA of 1SW non-maturing salmon ranks 37th out of the 39-year time-series. The continued low abundance of salmon stocks across North America, despite significant fishery reductions, further strengthens the conclusions that factors other than fisheries are constraining production.

COSEWIC, the organization that assesses the status of wildlife species which may be at risk of extinction in Canada, assessed the status of Atlantic salmon populations in Canada in 2010. Summaries of assessments on Atlantic salmon are currently available to the public on the COSEWIC website (www.cosewic.gc.ca) and will be submitted to the Federal Minister of the Environment in late summer 2011 for listing consideration under the Species at Risk Act (SARA). At that time, the full status reports and status appraisal summaries will be publicly available on the Species at Risk Public Registry (www.sararegistry.gc.ca).

Table 4.4.2.1. Reported harvests expressed as $2 S W$ salmon equivalents in North American salmon fisheries. Only midpoints of the estimated values have been used.

Figure 4.4.5.3. A comparison of the river age distribution of salmon from FSC (food social and ceremonial purposes) fishery in Lake Melville (FSC) compared with freshwater samples from North Labrador to those in 2000 to 2005.

Figure 4.4.6.1. Exploitation rates in North America on the North American stock complex of 1SW and 2SW salmon.

Figure 4.5.1. Proportion of rivers in the database by NASCO status category for Canada and for six regions/provinces of eastern Canada.

Figure 4.5.1.1. Time-series of wild smolt production from twelve monitored rivers in eastern Canada and one river in eastern USA. Smolt production is expressed as a proportion of the conservation egg requirements for the river.

Figure 4.5.2.1. Comparison of estimated medians of small returns (squares) to and small spawners (circles) in six geographic areas of North America. Returns and spawners for Scotia-Fundy do not include those from SFA 22 and a portion of SFA 23. Note the difference in scale for USA.

Figure 4.5.2.2. Comparison of estimated medians of large returns (squares) to and large spawners (circles) in six geographic areas of North America. Returns and spawners for Scotia-Fundy do not include those from SFA 22 and a portion of SFA 23. For USA, estimated spawners exceed the estimated returns due to adult stocking restoration efforts. Also, note the difference in scale for USA and the concern detailed in Section 4.5 .2 when interpreting the large increase in estimated 2009 Labrador large and 2SW return and spawners.

Figure 4.5.2.3. Comparison of the 2 SW conservation limits to the estimated medians of 2 SW returns (squares) to 2SW spawners (circles) in six geographic areas of North America. Returns and spawners for Scotia-Fundy do not include those from SFA 22 and a portion of SFA 23. For USA, estimated spawners exceed the estimated returns due to adult stocking restoration efforts. Also, note the difference in scale for USA and the concern detailed in Section 4.5 .2 when interpreting the large increase in estimated 2009 Labrador large and 2SW return and spawners.

Figure 4.5.4.1. Proportion of the conservation requirement attained in assessed rivers of the North American Commission area in 2010.

Figure 4.5.5.1. Standardized mean (one standard error bars) annual return rates of wild and hatchery origin smolts to 1SW and 2SW salmon to the geographic areas of North America. The standardized values are annual means derived from a general linear model analysis of rivers in a region. Survival rates were $\log$ transformed prior to analysis. Note y-scale differences among panels. Error bars are not included for estimates based on a single population.

Figure 4.5.5.2. The percent change in the five-year mean return rates for 1SW and 2SW salmon smolts returning to rivers of eastern North America in 2006 to 2010 compared with the previous period (2001 to 2005). Grey circles are for 1SW and dark squares are for 2SW dataseries. Populations with at least three data points in each of the two time periods are included in the analysis.

Figure 4.5.6.2.1. Estimates of PFA for 1SW maturing, 1SW non-maturing salmon and the total cohort of 1SW salmon based on the Monte Carlo simulations of the run-reconstruction model for NAC. Median and $95 \%$ CI interval ranges derived from Monte Carlo simulations are shown.

## 5 Atlantic salmon in the West Greenland Commission

### 5.1 NASCO has requested ICES to describe the events of the 2010 fishery and status of the stocks

### 5.1.1 Catch and effort in 2010

The salmon fishery is currently regulated according to The Government of Greenland Executive Order no. 21 of August 10, 2002. Only angling, fixed gillnets and driftnet are allowed to target salmon directly and the minimum mesh size has been 140 mm stretched since 1985. Fishing seasons have varied from year to year, but in general the season has started in August and continued until the quota was met or until a specified date later in the season. As in recent years the 2010 season was August 1 to October 31 .

The catch data provided were screened for errors and missing values. Catches were assigned to NAFO/ICES area by reported community. Reports which contained only the total number of salmon caught or the total catch weight without the number of salmon, were corrected using an average 2.75 kg gutted weight per salmon. Since 2005 it has been mandatory to report gutted weights, and data has been converted to whole weight by means of a conversion factor of 1.11.

Catches of Atlantic salmon decreased until the closure of the commercial fishery for export in 1998, but the subsistence fishery has been increasing in recent years. Catches were distributed among the six NAFO divisions on the west coast of Greenland and ICES Division XIV (East Greenland). A total catch of 40 t of salmon was reported for the 2010 fishery compared with 26 t of salmon in the 2009 fishery and represented an increase of $53 \%$ (Table 5.1.1.1). As in 2009, a catch of 1.7 t was also reported from East Greenland (Figure 5.1.1.1, Table 5.1.1.2), accounting for approximately $4.3 \%$ of the total reported catch. The increase in the total catch in 2010 is associated with the significant increase in the reported catch in NAFO Division 1A (Table 5.1.1.2) which represented $43 \%$ of the total reported catch. The total catch reported in this Division, 1.7 t , was the highest reported since 1989 at 17 t , compared with only 0.2 t in 2009 and 5 t in 2008. In contrast, the catches reported in other Divisions in 2010 were similar to previous years although the catches have fluctuated considerably. Such a large increase seems unlikely to be caused by a change in reporting practice and therefore implies that there may have been a more northerly distribution of salmon and potentially a higher overall abundance than in 2009. According to fishermen the salmon fishery was unusually good in 2010.

There is currently no quantitative approach for estimating the unreported catch but the 2010 value is likely to have been at the same level proposed in recent years ( 10 t ).

Of the total catch, 12 t was reported as commercial and 28 t was reported as being for private consumption. However, 15 t of the private consumption catch was reported by licensed fishers.

The seasonal distribution of catches has previously been reported to ICES up to 2001. However in recent years this has not been possible although fishers are required to report their catch immediately after fishing. Comparisons of summed reported catch and number of returned catch reports reveals that a large number of fishers report their total catch in only one report for the entire season although they are required to report after each fishing.

The Greenland Authorities received 389 reports of salmon catches from 208 fishers in 2010 compared with 238 reports from 145 fishers in 2009 (Table 5.1.1.3). The increase is due mainly to an increased number of people reporting and reports received in Division 1A. The total number of fishers reporting catches from all areas has steadily increased from a low of 41 in 2002 to its current level. These levels remain well below the 400 to 600 people reporting landings in the commercial fishery from 1987 to 1991. Since October 2006, the Greenland Home Rule Licence Office has broadcast TV requests that catch reports be submitted for the season. Despite this, the number of people reporting catches and the number of licensed fishers has fluctuated considerably in recent years.

These fluctuations in the numbers of people reporting catches and the catches themselves in each of the NAFO Divisions suggest that there are inconsistencies in the catch data and highlight the need for better data. The Working Group recommends that in addition to the information currently requested, fishers also be requested to provide information on catch site, catch date, numbers of nets, net dimensions, and numbers of hours the nets were fishing when submitting their catch logs. These data will help characterize the nature and extent of the current fishery. Therefore, the Working Group supports the proposal from the Greenlandic authorities for the introduction of a logbook as a condition of the licensing system for the salmon fishery at West Greenland. Such a logbook or equivalent reporting form should require the inclusion of the information above so that a more accurate fishing effort index can be developed.

### 5.1.2 Biological characteristics of the catches

## International sampling programme

The international sampling programme for the fishery at West Greenland agreed by the parties at NASCO continued in 2010. The sampling was undertaken by participants from Canada, Ireland, UK (Scotland), UK (England and Wales), and USA. Additionally, staff from the Greenland Institute of Natural Resources assisted with the overall coordination of the programme and sampling in Nuuk. Sampling began in August and continued through October.

Samplers were stationed in three different communities representing three different NAFO Divisions. As in previous years no sampling occurred in the fishery in East Greenland in 2010.

In the Baseline Sampling Programme, tissue and biological samples were collected from three landing sites: Sisimiut (NAFO Div. 1B), Nuuk (NAFO Div. 1D), and Qaqortoq (NAFO Division 1F; Figure 5.1.1.1).
In total 1265 individual salmon were inspected representing $10 \%$ by weight of the reported landings. Of these, 1261 were measured for fork length, 1155 for gutted weight and 453 for whole weight (Table 5.1.2.1). Scales samples were taken from 1265 salmon for age and origin determination and tissue was removed from 1240 for DNA analysis and subsequently used for assignment of continent of origin. In addition the sex of 360 fish was identified from gonadal examination.

Of the 21 adipose finclipped fish recovered, seven had either external or internal tags. There were no additional tags submitted to the Nature Institute by local fishers from unsampled fish. The overall breakdown was six coded wire tags (four from the Ireland, one from Norway and one from Canada) and one visual implant elastomer tag (USA).

Access to fish in support of the Baseline Sampling Programme was affected early in the sampling season in Nuuk. The sampler and representatives from the GNIR were informed by NAPP (Nuuk Hunter's and Fishermen's Association, the Nuuk department of KNAPK) that a fee would be requested for access to each fish sampled at the market. A meeting was organized with the sampler, NAPP representatives, GINR representatives and representatives from the Home Rule Government to rectify this situation. No solution was agreed to and the Nuuk samplers were unable to collect any more than 28 Baseline Samples from Nuuk in 2010. The samplers were able to collect Enhanced Samples as these fish were purchased directly from the fishermen and the NAPP did not have a problem with this arrangement. This problem only occurred in Nuuk. In recent years there have been similar discussions with representatives from NAPP, although the situation only lasted a few days before sampling resumed without monetary compensation. In total, the Nuuk samplers were only able to collect of 230 samples, 28 from the baseline sampling and 202 from the Enhanced Sampling Programme. This represents $18 \%$ of the samples collected for 2010. However, the samplers documented a total of approximately 1600 salmon landed in Nuuk during the time they were present.

The decentralized landings and broad geographic distribution of the fishery causes practical problems for the sampling teams; however, the sampling programme was successful in adequately sampling the Greenland catch, both temporally and spatially. Additional access to the fish landed in Nuuk, especially in future once the Enhanced Sampling Programme is completed, is essential.

Reported landings amounted to 38 metric tons (not including the East Greenland catch). Non-reporting of harvest becomes evident upon comparison of the reported landings to the sample data. Since 2002, in at least one of the divisions where international samplers were present, the sampling team observed more fish than were reported as being landed. When there is this type of weight discrepancy, the reported landings are adjusted according to the total weight of the fish identified as being landed during the sampling effort and these adjusted landings are carried forward for all future assessments. In 2010 this occurred in all three sampled communities. The total discrepancy equalled 5.1 t . The reported landings and subsequent adjusted landings for 2002-2010 are presented in Table 5.1.2.2.

Biological characteristics (length, weight, and age) were recorded for all sampled fish. Overall, the mean sampled fork length was 66.5 cm and the mean gutted weight was 3.05 kg across all sea ages. In 2010, the mean length and weight of North American 1SW salmon was 66.7 cm and 3.44 kg weight and the mean for European 1SW salmon was 65.2 cm and 3.23 kg . The North American estimate is an increase from 2009 while the European estimate is a decrease, but both estimates are greater than the previous ten year mean.

Information is available from sampling the fishery at West Greenland fishery to examine the changing weights and condition factors of 1SW non-maturing salmon (Table 5.1.2.3). Over the period of sampling ( 1969 to 2010) the mean weight of these fish appeared to decline from high values in the 1970s to the lowest mean weights of the time-series in 1990 to 1995, before increasing subsequently to 2010 (Figure 5.1.2.1). These mean weight trends are unadjusted for the period of sampling and it is known that salmon grow quickly during the period of sampling in the fishery from August to October. Therefore the Working Group examined the variations in whole weight adjusted for date of sampling and length of fish. The data available for analysis covered the period 2002 to 2010.

The number of samples of known continent of origin of 1SW non-maturing salmon in the database ranged from 329 to 1533 fish originating from NAC annually and 116 to 482 fish from NEAC. Samples were most commonly available from standard weeks 33 (August 13th to August 19th) to 40 (October 1st to October 7th) for salmon from both NAC and NEAC, with the fewest samples in standard weeks 31 and 44 .
Date of sampling within the year alone accounted for $19 \%$ of the total variance in whole weight, but continent of origin was not a significant explanatory variable ( $\mathrm{P}>$ 0.1 ) when date of sampling was included in the model. There was a significant year effect after correcting for date of sampling; whole weights were highest in 2010 and lowest in 2002 and 2007. Condition of the fish (expressed as the predicted weight at a standardized length of 64 cm ) increased almost monotonically with increasing standard week and salmon from NEAC tended to have slightly higher weights at length than NAC fish, except for the end of the sampling period (week 44) when NAC fish had higher condition (Figure 5.1.2.2). However, there were very few samples from week 31 all of which were taken in 2008 or week 44 which were available only from 2008 and 2010.

For the standardized sampling week 36 (from which the most samples were obtained over 2002 to 2010) and for a standardized fork length of 64 cm , there was a significant year effect in the predicted whole weight of salmon for 2002 to 2010 (Figure 5.1.2.3). The heaviest fish at length for NAC were sampled in 2009 and the lightest fish at length in 2005. For NEAC origin salmon, the lightest fish at length were also sampled in 2005 and the heaviest fish at length were sampled in 2002 (Figure 5.1.2.3).
The analysis of condition of salmon over the period 2002 to 2010 contrasts with the interpretation of salmon size at West Greenland based entirely on weights or lengths unadjusted for the period of sampling or for the length of the fish. With the exception of the 2005 sampling year for NAC and 2005 as well as 2002 for NEAC, there is no apparent change in condition of 1SW non-maturing salmon at West Greenland. The trend in increasing weights from the samples can be attributed to both increasing length and variations in sampling period. The longer time-series of sampling data from West Greenland should be analysed in a similar way to assess the extent of the variations in condition over the time period corresponding to the large variations in productivity as identified by the NAC and NEAC assessment and forecast models.
North American salmon up to river age six were caught at West Greenland in 2010 (Table 5.1.2.4), comprising predominantly 2 year old ( $21.7 \%$ ), 3 year old ( $47.9 \%$ ) and 4 year old ( $21.7 \%$ ) smolts. The river ages of European salmon ranged from 1 to 5 years in the river (Table 5.1.2.4). Of these, $57.1 \%$ were river age 2 with river age 3 comprising 27.3\%.

As expected, the 1 SW age group dominated the collection at $98.0 \%$ (Table 5.1.2.5). This value was an increase from the 2009 ( $92.9 \%$ ) value. The increased proportion of 1SW fish was evident for both North American and European origin contributors and was accompanied by corresponding decreases in the contribution of older age fish.

As part of the sampling programme a total of 360 individuals had their sex identified by gonadal examination. The sex ratio was $15.8 \%$ males ( $n=57$ ) to $84.2 \%$ females ( $\mathrm{n}=303$ ).

In addition to the Baseline Sampling Programme described above, an Enhanced Sampling Programme (SALSEA Greenland) was developed to conduct broader and more detailed sampling on a fixed number of fish harvested from the waters off West Greenland. The Enhanced Sampling was designed to be integrated within the Base-
line Sampling Programme's infrastructure. Fresh whole fish were purchased directly from individual fishers and these fish were included in the Baseline Sampling Programme plus a more detailed sampling programme (Enhanced Sampling). The SALSEA Greenland Programme is an integral part of the larger SALSEA research programme.

The enhanced samples collected were:

- Counts and preservation of sea lice;
- Preserved gill, pyloric caeca, spleen, kidney tissue samples for disease analysis;
- Preserved muscle tissue for lipid content analysis;
- Preserved liver, dorsal muscle, caudal fin and scales samples for stable isotope analysis;
- Preserved stomachs for feeding ecology studies;
- Preserved intestines, pyloric caeca, gill arch, liver, spleen, kidney for parasite analysis;
- Preserved otoliths for elemental analysis;
- Preserved kidney samples for ISAv.

The Enhanced Sampling Programme was successfully undertaken in 2010. A total of 358 fresh whole fish were purchased directly from individual fishers. All carcasses, post sampling, were donated for consumption to the communities where the sampling took place.

### 5.1.3 Continent of origin of catches at West Greenland

A total of 1240 useable genetic samples were collected from three NAFO divisions: Sisimiut in 1B ( $n=637$ ), Nuuk in 1D $(n=227)$, and Qaqortoq in 1F $(n=376)$. DNA isolation and the subsequent microsatellite analysis were performed (King et al., 2001). A database of approximately 5000 Atlantic salmon genotypes of known origin was used as a baseline to assign these individuals to continent of origin. In total, $79.9 \%$ of the salmon sampled were of North American origin and 20.1\% were determined to be of European origin. The NAFO Division-specific continent of origin assignments in 2010 are presented in Table 5.1.3.1.

These data reveal the large proportion of North American origin individuals contributing to the fishery over the past ten years (Table 5.1.3.2). The variability in the recent continental representation among divisions underscores the need to sample multiple NAFO regions to achieve the most accurate estimate of the contribution of fish from each continent to the mixed-stock fishery.

The estimated weighted proportions of North American and European salmon from 1987-2010 are displayed in Table 5.1.3.2 and the weighted numbers of North American and European Atlantic salmon caught at West Greenland (excluding the reported harvest from ICES area XIV) were calculated. In 2010, approximately 10000 (34 t) North American origin fish and approximately $2600(9 \mathrm{t})$ European origin fish were harvested. These totals remain among the lowest in the time-series, although they are the highest on record since 2001.

The Working Group again recommends a continuation and expansion of the broad geographic sampling programme (multiple NAFO divisions) to more accurately estimate continent of origin in the mixed-stock fishery.

### 5.2 Status of stocks

The stock complex at West Greenland is below conservation limits and thus suffering reduced reproductive capacity. In European and North American areas, the overall status of stocks contributing to the West Greenland fishery is among the lowest recorded, and as a result, the abundance of salmon within the West Greenland area is thought to be extremely low compared with historical levels. A more detailed overview of status of stocks in the NEAC and NAC areas is presented in the relevant commission sections (Sections 3 and 4).

In summary, North American 2SW spawner estimates for the six geographic areas indicated that all areas were below their CL, (Figure 4.5.2.3) in 2010 and are suffering reduced reproductive capacity. Within each of the geographic areas there are varying numbers of individual river stocks which are failing to meet conservation limits, particularly in Scotia-Fundy and the USA. The estimated exploitation rate of North American origin salmon in North American fisheries has declined (Figure 4.4.6.1) from approximately $80 \%$ in 1971 to $15 \%$ in 2010 for 2 SW salmon and from approximately $68 \%$ in 1973 to $19 \%$ in 2010 for 1SW salmon. 2010 exploitation rates on 1SW and 2SW salmon remained among the lowest in the time-series, although exploitation rates on 1SW have increased slightly since 2007.
The status of stocks in the four Northeast Atlantic stock complexes are assessed with respect to the spawning escapement reserve (SER) and prior to the commencement of distant water fisheries. All four stock complexes (Northern NEAC 1SW and MSW and Southern NEAC 1SW and MSW) are considered to be at full reproductive capacity. However, at a country level, stock status from several jurisdictions is below CL and further, within the countries there are many river stocks which are not meeting CLs. Exploitation rates on these stocks are currently at their lowest level historically. Exploitation rates on 1SW salmon in the Northern NEAC and Southern NEAC area in 2010 was $40 \%$ and $14 \%$ respectively, both of which were below the five and ten years averages; for the MSW stocks, the exploitation rates in 2010 were $45 \%$ and $13 \%$ respectively, also below the five and ten year averages.

The results from the standardized analysis of length, weight and condition for the period 2002 to 2010, contrasts with the interpretation of salmon size at West Greenland based entirely on weights or lengths unadjusted for the period of sampling or for the length of the fish (Section 5.1.2). With the exception of the 2005 sampling year for NAC and 2005 as well as 2002 for NEAC, there is no apparent change in condition of 1SW non-maturing salmon at West Greenland. The trend in increasing weights from the samples can be attributed to both increasing length and variations in sampling period.

Table 5.1.1.1. Nominal catches of salmon at West Greenland since 1977 (metric tons round fresh weight).

| Year | Total | Quota | Comments |

Figure 5.1.1.1. Location of NAFO divisions along the coast of West Greenland.

Figure 5.1.2.1. Sampled mean whole weight (kg) of 1SW non-maturing salmon by continent of origin over the period 1969 to 2010. The weights are not adjusted for the date of sampling or for the length of the fish.

Figure 5.1.2.2. Comparison of predicted whole weight ( g ; mean; +/- 2 std errors) of 1 SW nonmaturing salmon from NAC and NEAC, adjusted to a common fork length of 64 cm , by standard week of sampling, all years ( 2002 to 2010 ) combined. Very few samples ( 64 from NAC, 4 from NEAC) are available from week 31 and all the samples were from the 2008 sampling year. The diagonal line is the equivalency line.

Figure 5.1.2.3. Predicted whole weight (g) (mean, +/- 2 std errors) of 1SW non-maturing salmon, by continent of origin, sampled at West Greenland and adjusted for standard sampling week 36 and a standardized fork length of 64 cm .

## 6 Additional term of reference from ICES MSFDSG and SIASM

In a communication dated March 10, 2011, the chair of the ICES Science Committee and the Chair of the Advisory Committee requested assistance from ICES expert groups to two groups created jointly by ACOM and SCICOM, the Marine Strategy Directive Framework Steering Group (MSDFSG) and the Strategic Initiative on Area Based Science and Management (SIASM).

These additional TORs from ICES steering groups are an additional task to the WGNAS which is currently fully committed to addressing questions by NASCO. These specific TORs may be better considered by other expert groups tasked specifically with such one-off requests and who would not also be tasked with responding to the large suite of questions on fisheries descriptions, stock status and provision of catch advice.

### 6.1 TOR from MSFDSG

ICES requested all its Expert Groups (EG) to identify and describe the work streams of relevance to the Descriptors in Annex I of Directive 2008/56/EC regarding criteria for good environmental status of marine waters. The criteria and methodologies are set out in the COMMISSION DECISION report of 1 September 2010 (notified under document $C(2010) 5956)$. In addition, the EGs are asked to provide views on what good environmental status might be for those descriptors, including methods that could be used to determine status.

The descriptors to be used to assess the good environmental status relevant to Directive 2008/56/EC are:

| Descriptor | Characteristic |
| :--- | :--- |
| 1. Biological diversity | Biological diversity is maintained. The quality and occurrence of <br> habitats and the distribution and abundance of species are in line with <br> prevailing physiographic, geographic and climate conditions. |
| 2. Non-indigenous species | Non-indigenous species introduced by human activities are at levels <br> that do not adversely alter the ecosystem. |
| 3. Safe biological limits | Populations of all commercially exploited fish and shellfish are within <br> safe biological limits, exhibiting a population age and size distribution <br> that is indicative of a healthy stock. |
| 4. State of marine foodwebs | All elements of the marine foodwebs, to the extent that they are <br> known, occur at normal abundance and diversity and levels capable <br> of ensuring the long-term abundance of the species and the retention <br> of their full reproductive capacity. |
| 5. Human-induced <br> eutrophicationHuman-induced eutrophication is minimized, especially adverse <br> effects thereof, such as losses in biodiversity, ecosystem degradation, <br> harmful algal blooms and oxygen deficiency in bottom waters. |  |
| 6. Seabed integrity | Seabed integrity is at a level that ensures that the structure and <br> functions of the ecosystems are safeguarded and benthic ecosystems, <br> in particular, are not adversely affected. |
| 7. Alteration of <br> hydrographical conditions | Permanent alteration of hydrographical conditions does not adversely <br> affect marine ecosystems. |
| 8. Contaminants in the <br> environment | Concentrations of contaminants are at levels not giving rise to <br> pollution effects. |
| 9. Contaminants in fish and <br> seafood | Contaminants in fish and other seafood for human consumption do <br> not exceed levels established by Community legislation or other <br> relevant standards. |

| Descriptor | Characteristic |
| :--- | :--- |
| 10. Marine litter | Properties and quantities of marine litter do not cause harm to the <br> coastal and marine environment. |
| 11. Energy projects | Introduction of energy, including underwater noise, is at levels that <br> do not adversely affect the marine environment. |

The following overview summarizes the scientific inputs for the assessment of status of Atlantic salmon in the North Atlantic by the Working Group and the potential contributions of the Working Group to the work of the ICES Marine Strategy (MSFDG). In addition, what would be considered good environmental status for the descriptors and methods to determine the status are presented, when applicable.

## Biological diversity

Elements of WGNAS contributing to determination of status:

- At the species level, WGNAS provides information on the distributional range and the distributional pattern within the range of Atlantic salmon in the North Atlantic rivers. In a large number of rivers and geographic areas, estimates of population size, population abundance and population demographic characteristics (e.g. body size or age-class structure, sex ratio, fecundity rates, survival/ mortality rates) are available. The descriptions of the population genetic structure are now well known or will be over the next few years.
- At the habitat level, the habitat requirements of the species and the availability and quality of the freshwater habitat are well known but such information is not routinely assessed and reviewed by WGNAS. Information on habitat requirements at sea and the changes in habitat quality and accessibility are less well known.
- At the ecosystem level, the relative abundance of Atlantic salmon in the freshwater fish communities is relatively well known and variations in abundance and characteristics are monitored in a large number of rivers annually but such information is not routinely assessed and reviewed by WGNAS. Similar information is generally lacking for the marine portion of the life cycle, Atlantic salmon being a less abundant fish species (in number and weight) within the pelagic fish community of the North Atlantic.

Environmental indicators and methods to determine status:

- Variations in abundance of Atlantic salmon and distribution and the relative abundance of salmon within the freshwater fish communities would be an appropriate indicator of biological diversity.

## Non-indigenous species

Elements of WGNAS contributing to determination of status:

- The introduction of non-indigenous species in Atlantic salmon rivers and their consequences on populations are frequently documented in WGNAS. Recent examples of these interactions include the impacts of the transfer of parasites (Gyrodactylus salaris in Europe), non-indigenous expansions into Iceland of diadromous (sea lamprey) and marine (flounder) species, rainbow trout in Europe, and freshwater predator species (Esox sp., Micropterus dolomuei) in Canadian and USA waters. Trends in abundance, temporal oc-
currence and spatial distribution in the wild of some of these species, including in relation to the main vectors and pathways of spreading of such species are information which have been discussed at WGNAS.

Environmental indicators and methods to determine status:

- Documentation of non-indigenous species, changes in distribution through time are indicators of environmental health which could be documented by national authorities.

## Safe biological limits

Elements of WGNAS contributing to determination of status:

- Atlantic salmon status is assessed relative to defined conservation limits (limit reference point) and management of fisheries is based on management objectives of achieving conservation limits in individual rivers. The status of Atlantic salmon in the North Atlantic is assessed relative to these conservation limits annually by WGNAS. Conservation limits for sea age groups are also defined to guide management for age structure and population diversity.

Environmental indicators and methods to determine status:

- Conservation limits and the compliance of stocks in individual rivers is the appropriate indicator for this descriptor.

## State of marine foodwebs

Elements of WGNAS contributing to determination of status:

- WGNAS would not input into this descriptor.

## Human-induced eutrophication

Elements of WGNAS contributing to determination of status:

- Atlantic salmon are particularly vulnerable to degraded water quality particularly in freshwater and estuaries. WGNAS opportunistically reviews reports of Atlantic salmon populations impacted by human-induced activities, but assessment of eutrophication or water quality is not a generic term of reference for WGNAS.

Environmental indicators and methods to determine status:

- Monitoring of juvenile salmon abundances and the fish communities could be used to assess water quality and eutrophication states of the freshwater environment. Indicators of environmental quality that relate to Atlantic salmon are defined in relation to the EU Water Framework Directive.

## Seabed integrity

Elements of WGNAS contributing to determination of status:

- WGNAS would not input into this descriptor, salmon are pelagic ocean species and fisheries are concentrated in rivers or very near the coast, or when at sea, using pelagic gear.

## Alteration of hydrographical conditions

Elements of WGNAS contributing to determination of status:

- Atlantic salmon during their life stages residing and migrating through estuaries and in freshwater are particularly vulnerable to alterations in hydrographical conditions in freshwater and estuaries. There is a large amount of scientific literature on the impacts of barrages on Atlantic salmon populations, including extirpations of populations and on technological approaches to facilitate fish passage. The description of threats to Atlantic salmon from modified flow regimes and fish passage have been terms of reference considered by WGNAS but not on an annually recurring basis.

Environmental indicators and methods to determine status:

- Indicators would include estimates of habitat loss due to barrages and modified flow regimes, number of rivers impacted by barrages, progress in removing deterrents or improving access to salmon to habitat, are all potential indicators of environmental status for this descriptor.

## Contaminants in the environment

Elements of WGNAS contributing to determination of status:

- WGNAS would not routinely assess or report on contaminant levels leading to pollution. However, Atlantic salmon have been revealed to be susceptible to non-acute exposure to various chemicals whose levels in the environment can be at low concentrations but that can affect salmon developmental states, particularly for the vulnerable stages transitioning between freshwater and the marine environments. Such interactions are documented in literature and discussed at WGNAS on an ad hoc basis.

Environmental indicators and methods to determine status:

- Work to define the environmental indicators for these chemicals is not being conducted by WGNAS.

## Contaminants in fish and seafood

Elements of WGNAS contributing to determination of status:

- WGNAS would not input into this descriptor.

## Marine litter

Elements of WGNAS contributing to determination of status:

- WGNAS would not input into this descriptor.

## Energy projects

Elements of WGNAS contributing to determination of status:

- As indicated for descriptor 7, Atlantic salmon populations are vulnerable to modifications in fish passage and water regime regulation. The description of threats to Atlantic salmon from modified flow regimes and fish passage have been terms of reference considered by WGNAS but not on an annual basis.

Environmental indicators and methods to determine status:

- Indicators as for descriptor 7 above would be appropriate.

## Implications for WGNAS

WGNAS regularly meets to address questions posed to ICES by NASCO. The addition of a term of reference to address on annual basis the elements of the descriptors of good environmental status would be an important workload addition for WGNAS and would require additional national participation of specialists in habitat and environmental quality. Elements from WGNAS specific to population abundance and status relative to safe biological limits for Atlantic salmon are contained in WGNAS reports and could be considered by MSFDG in delivery of their tasks.

### 6.2 ToR from SIASM

The main objective of the Strategic Initiative on Area Based Science and Management (SIASM) is to demonstrate to ICES clients, Member Countries and stakeholders that ICES has the expertise and facilities to deliver solid, robust and independent science and advice on marine area based management and spatial planning.

From SIASM, the following term of reference was added to all EGs for 2011:

- take note of and comment on the Report of the Workshop on the Science for area-based management: Coastal and Marine Spatial Planning in Practice (WKCMSP);
- provide information that could be used in setting pressure indicators that would complement biodiversity indicators currently being developed by the Strategic Initiative on Biodiversity Advice and Science (SIBAS). Particular consideration should be given to assessing the impacts of very large renewable energy plans with a view to identifying/predicting potentially catastrophic outcomes;
- identify spatially resolved data, for e.g. spawning grounds, fishery activity, habitats, etc.

The WGNAS took note of the workshop report referred to in the ToR and has commented on the recommendations of the workshop for science input in the development of area-based management. Specifically, WGNAS has the capacity to document the spatial locations of Atlantic salmon rivers as well as information on timing of migrations between rivers and estuaries of specific river stocks throughout the species distributional range. Status of river-specific stocks is documented annually and this could be used as a pressure indicator that complements (in this case, similar to descriptor 3 in Section 6.1) the descriptors of interest to MSFDSG. For this, reference could be made to the database of Atlantic salmon rivers in the North Atlantic which has been compiled by NASCO based on inputs from countries of the North Atlantic. Recently, work has been undertaken to rescue and secure tag and recovery data of Atlantic salmon in the North Atlantic, the data being georeferenced and time stamped (ICES 2007a; ICES 2008b; ICES 2009b). In the next few years, extensive data on post-smolt migrations and distributions at sea will become available through the SALSEA-MERGE initiative in the Northeast Atlantic (ICES 2010b).

The potential impacts of renewal energy plans have been raised by NASCO with a question to ICES. In the context of Atlantic salmon, the impacts of renewal energy installations are important and are a growing threat to salmon, as discussed in Sec-
tion 2.3.2 and the information provided in this report is a preliminary look at the question.

## Annex 4: Reported catch of Atlantic salmon

Reported catch of Atlantic salmon in numbers and weight (tonnes round fresh weight) by sea -age class. Catches reported for 2010 may be provisional. Methods used for estimating age composition given in footnotes.

Annex 4 (continued).

Annex 4 (continued).

Annex 4 (continued).

Annex 4 (continued).

1. MSW includes all sea ages $>1$, when this cannot be broken down.

Different methods are used to separate 1SW and MSW salmon in different coutries

- Scale reading: Faroe Islands, Finland (1996 onwards), France, Russia, USA and West Greenland.

Size (split weightllength): Canada ( 2.7 kg for nets; 63 cm for rods), Finland up until $1995(3 \mathrm{~kg})$,
Iceland (various splits used at different times and places), Norway $(3 \mathrm{~kg})$ UK Scotland ( 3 kg in som 3.7 kg in others),
Iceland (various splits used at different times and places), Norway ( 3 kg ), UK Scotland ( 3 kg in some places and 3.7 kg in others),
All countries except Scotland report no problems with using weight to catergorise catches into sea age classes; mis-classification may be very high in some years.
In Norway, catches shown as 35 W refer to salmon of 3 SW or greater
2. Based on catches in Asturias (80-90\% of total catch). No data for 2008 , previous year data is used.

## Annex 5: Input data for run reconstruction of Atlantic salmon in the NEAC area

Annex 5.i. Input data for NEAC Pre Fishery Abundance analysis using Monte Carlo simulation R. Tana/Teno (Finland/Norway).

Annex 6: Input data for run-reconstruction of Atlantic salmon in the NAC area used to do the run-reconstruction, and estimates of returns and spawners by size group and age group for North America

Annex 6.i. Input data for the fishery at West Greenland used in the run reconstruction model.

Annex 6.ii. Input data for sea fisheries on large salmon and small salmon from Newfoundland and Labrador used in the run reconstruction model. FSC Labrador represents harvests from Labrador in aboriginal fisheries for food, social and ceremonial purposes (FSC).

## Annex 7: Glossary of acronyms used in this Report

1SW (One-Sea-Winter) Maiden adult salmon that has spent one winter at sea.
2SW (Two-Sea-Winter) Maiden adult salmon that has spent two winters at sea.
ACOM (Advisory Committee) of ICES. The Committee works on the basis of scientific analysis prepared in the ICES expert groups and the advisory process include peer review of the analysis before it can be used as basis for the advice. The Advisory Committee has one member from each member country under the direction of an independent chair appointed by the Council.

BCI (Bayesian Credible Interval) The Bayesian equivalent of a confidence interval. If the $90 \% \mathrm{BCI}$ for a parameter A is 10 to 20 , there is a $90 \%$ probability that A falls between 10 and 20.

BHSRA (Bayesian Hierarchical Stock and Recruitment Approach) Models for the analysis of a group of related stock-recruit datasets. Hierarchical modelling is a statistical technique that allows the modelling of the dependence among parameters that are related or connected through the use of a hierarchical model structure. Hierarchical models can be used to combine data from several independent sources.
$\mathbf{C \& R}$ (Catch and Release) Catch and release is a practice within recreational fishing intended as a technique of conservation. After capture, the fish are unhooked and returned to the water before experiencing serious exhaustion or injury. Using barbless hooks, it is often possible to release the fish without removing it from the water (a slack line is frequently sufficient).

CL, i.e. Slim (Conservation Limit) Demarcation of undesirable stock levels or levels of fishing activity; the ultimate objective when managing stocks and regulating fisheries will be to ensure that there is a high probability that undesirable levels are avoided.

COSEWIC (Committee on the Status of Endangered Wildlife in Canada) COSEWIC is the organization that assesses the status of wild species, subspecies, varieties, or other important units of biological diversity, considered to be at risk of extinction in Canada. COSEWIC uses scientific, Aboriginal traditional and community knowledge provided by experts from governments, academia and other organizations. Summaries of assessments on Atlantic salmon are currently available to the public on the COSEWIC website (www.cosewic.gc.ca)

Cpue (Catch Per Unit of Effort) A derived quantity obtained from the independent values of catch and effort.

CWT (Coded Wire Tag) The CWT is a length of magnetized stainless steel wire 0.25 mm in diameter. The tag is marked with rows of numbers denoting specific batch or individual codes. Tags are cut from rolls of wire by an injector that hypodermically implants them into suitable tissue. The standard length of a tag is 1.1 mm .

DFO (Department of Fisheries and Oceans) DFO and its Special Operating Agency, the Canadian Coast Guard, deliver programmes and services that support sustainable use and development of Canada's waterways and aquatic resources.

DNA (Deoxyribonucleic Acid) DNA is a nucleic acid that contains the genetic instructions used in the development and functioning of all known living organisms (with the exception of RNA- Ribonucleic Acid viruses). The main role of DNA molecules is the long-term storage of information. DNA is often compared with a set of blueprints,
like a recipe or a code, because it contains the instructions needed to construct other components of cells, such as proteins and RNA molecules.

DST (Data Storage Tag) A miniature data logger with sensors including salinity, temperature, and depth that is attached to fish and other marine animals.

ECOKNOWS (Effective use of Ecosystems and biological Knowledge in fisheries) The general aim of the ECOKNOWS project is to improve knowledge in fisheries science and management. The lack of appropriate calculus methods and fear of statistical over partitioning in calculations, because of the many biological and environmental influences on stocks, has limited reality in fisheries models. This reduces the biological credibility perceived by many stakeholders. ECOKNOWS will solve this technical estimation problem by using an up-to-date methodology that supports more effective use of data. The models will include important knowledge of biological processes.

ENPI CBC (European Neighbourhood and Partnership Instrument Cross-Border Cooperation) ENPI CBC is one of the financing instruments of the European Union. The ENPI programmes are being implemented on the external borders of the EU. It is designed to target sustainable development and approximation to EU policies and standards supporting the agreed priorities in the European Neighbourhood Policy Action Plans, as well as the Strategic Partnership with Russia.

FWI (Framework of Indicators) FWI indicate if any significant change in the status of stocks used to inform the previously provided multi-annual management advice had occurred.

ICPR (The International Commission for the Protection of the River Rhine) ICPR coordinates the ecological rehabilitation programme involving all countries bordering the river Rhine. This programme was initiated in response to catastrophic river pollution in Switzerland in 1986 which killed hundreds of thousands of fish. The programme aims to bring about significant ecological improvement of the Rhine and its tributaries enabling the re-establishment of migratory fish species such as salmon.

ISAV (Infectious Salmon Anemia Virus) ISA is a highly infectious disease of Atlantic salmon caused by an enveloped virus.

LE (Lagged Eggs) The summation of lagged eggs from 1 and 2 sea winter fish is used for the first calculation of PFA.

MSY (Maximum Sustainable Yield) The largest average annual catch that may be taken from a stock continuously without affecting the catch of future years; a constant longterm MSY is not a reality in most fisheries, where stock sizes vary with the strength of year classes moving through the fishery.
MSW (Multi-Sea-Winter) An adult salmon which has spent two or more winters at sea or a repeat spawner.
NG (Nunatsiavut Government) NG is one of four subsistence fisheries harvested salmonids in Labrador. NG members are fishing in the northern Labrador communities.

PFA (Pre-Fishery Abundance) The numbers of salmon estimated to be alive in the ocean from a particular stock at a specified time. In the previous version of the stock complex Bayesian PFA forecast model two productivity parameters are calculated, for the maturing (PFAm) and non-maturing (PFAnm) components of the PFA. In the updated version only one productivity parameter is calculated, and used to calculate total PFA, which is then split into PFAm and PFAnm based upon the proportion of PFAm (p.PFAm).

PGA (The Probabilistic-based Genetic Assignment model) An approach to partition the harvest of mixed-stock fisheries into their finer origin parts. PGA uses Monte Carlo sampling to partition the reported and unreported catch estimates to continent, country and within country levels.

PIT (Passive Integrated Transponder) PIT tags use radio frequency identification technology. PIT tags lack an internal power source. They are energized on encountering an electromagnetic field emitted from a transceiver. The tag's unique identity code is programmed into the microchip's nonvolatile memory.

Q Areas for which the Ministère des Ressources naturelles et de la Faune manages the salmon fisheries in Québec.

RR model (Run-Reconstruction model) RR model is used to estimate PFA and national CLs.

RVS (Red Vent Syndrome) The condition, known as RVS, has been noted since 2005, and has been linked to the presence of a nematode worm, Anisakis simplex. This is a common parasite of marine fish and is also found in migratory species. The larval nematode stages in fish are usually found spirally coiled on the mesenteries, internal organs and less frequently in the somatic muscle of host fish.

SALSEA (Salmon at Sea) SALSEA is an international programme of co-operative research designed to improve understanding of the migration and distribution of salmon at sea in relation to feeding opportunities and predation. It differentiates between tasks which can be achieved through enhanced coordination of existing ongoing research, and those involving new research for which funding is required.

SARA (Species At Risk Act) SARA is a piece of Canadian federal legislation which became law in Canada on December 12, 2002. It is designed to meet one of Canada's key commitments under the International Convention on Biological Diversity. The goal of the Act is to protect endangered or threatened organisms and their habitats. It also manages species which are not yet threatened, but whose existence or habitat is in jeopardy. SARA defines a method to determine the steps that need to be taken in order to help protect existing relatively healthy environments, as well as recover threatened habitats. It identifies ways in which governments, organizations, and individuals can work together to preserve species at risk and establishes penalties for failure to obey the law.

SCICOM (Science Committee) of ICES. SCICOM is authorized to communicate to third-parties on behalf of the Council on science strategic matters and is free to institute structures and processes to ensure that inter alia science programmes, regional considerations, science disciplines, and publications are appropriately considered.

SER (Spawning Escapement Reserve) The CL increased to take account of natural mortality between the recruitment date (1st January) and return to home waters.

SFA (Salmon Fishing Areas) Areas for which the Department of Fisheries and Oceans (DFO) Canada manages the salmon fisheries.

SGBICEPS (The Study Group on the Identification Of Biological Characteristics For Use As Predictors Of Salmon Abundance) The ICES study group established to complete a review of the available information on the life-history strategies of salmon and changes in the biological characteristics of the fish in relation to key environmental variables.

SGBYSAL (Study Group on the Bycatch of Salmon in Pelagic Trawl Fisheries). The ICES study group that was established in 2005 to study Atlantic salmon distribution at sea and fisheries for other species with a potential to intercept salmon.

SGEFISSA (Study Group on Establishing a Framework of Indicators of Salmon Stock Abundance) A study group established by ICES that met in November 2006.

SGERAAS (Study Group on Effectiveness of Recovery Actions for Atlantic Salmon) SGERASS had been established by ICES. The task of study group is to provide a review of examples of successes and failures in wild salmon restoration and rehabilitation and develop a classification of activities which could be recommended under various conditions or threats to the persistence of populations.

SGSSAFE (Study Group on Salmon Stock Assessment and Forecasting). The study group established to work on the development of new and alternative models for forecasting Atlantic salmon abundance and for the provision of catch advice.

Slim, i.e. CL (Conservation Limit) Demarcation of undesirable stock levels or levels of fishing activity; the ultimate objective when managing stocks and regulating fisheries will be to ensure that there is a high probability that the undesirable levels are avoided.

SST (Sea surface temperatures) the water temperatures close to the surface. In practical terms, the exact meaning of surface varies according to the measurement method used. A satellite infrared radiometer indirectly measures the temperature of a very thin layer of about 10 micrometres thick of the ocean which leads to the phrase skin temperature. A microwave instrument measures subskin temperature at about 1 mm . A thermometer attached to a moored or drifting buoy in the ocean would measure the temperature at a specific depth, (e.g. at one meter below the sea surface). The measurements routinely made from ships are often from the engine water intakes and may be at various depths in the upper 20 m of the ocean. In fact, this temperature is often called sea surface temperature, or foundation temperature.

TAC (Total Allowable Catch) The quantity of fish that can be taken from each stock each year.

WFD (Water Framework Directive) Directive 2000/60/EC (WFD) aims to protect and enhance the water environment, updates all existing relevant European legislation, and promotes a new approach to water management through river-based planning. The Directive requires the development of River Basin Management Plans (RBMP) and Programmes of Measures (PoM) with the aim of achieving Good Ecological Status or, for artificial or more modified waters, Good Ecological Potential.

WGF (West Greenland Fishery) Regulatory measures for WGF have been agreed by the West Greenland Commission of NASCO for most years since NASCO's establishment. These have resulted in greatly reduced allowable catches in the WGF, reflecting declining abundance of the salmon stocks in the area.
WKADS (Workshop on Age Determination of Salmon) WKADS had recently taken place in Galway, Ireland (January 18th to 20th, 2011) with the objectives of reviewing, assessing, documenting and making recommendations on current methods of ageing Atlantic salmon. The Workshop had primarily focused on digital scale reading to measure age and growth, with a view to standardization.

WKDUHSTI (Workshop on the Development and Use of Historical Salmon Tagging Information from Oceanic Areas) The Workshop established by ICES was held in February 2007.

WKSHINI (Workshop on Salmon historical information-new investigations from old tagging data) The Workshop is set to meet from 18-20 September 2008 in Halifax, Canada.

WKLUSTRE (Workshop on Learning from Salmon Tagging Records) The ICES Workshop established to complete compilation of available data and analyses of the resulting distributions of salmon at sea. WKLUSTRE will report by 30 November 2009 for the attention of the WGNAS.

This glossary has been extracted from various sources, but chiefly the EU SALMODEL report (Crozier et al., 2003).

## Annex 8: NASCO has requested ICES to identify relevant data deficiencies, monitoring needs and research requirements

The Working Group recommends that it should meet in 2012 to address questions posed by ICES, including those posed by NASCO. The Working Group intends to convene in the headquarters of the ICES in Copenhagen, Denmark from 20 to 29 March 2012.

## List of recommendations

1 ) The Working Group recommends that further work be undertaken to address the issues raised by the Workshop on Age Determination of Salmon regarding protocols, inter-laboratory calibration and quality control as they relate to the interpretation of age and calculation of growth and other features from scales and a second Workshop should be convened to facilitate this work and reporting.
2 ) The Working Group recommends continuing with the annual compilation of salmon tag releases and encourages further use of the scientific information gathered from tagging programmes.
3 ) The Working Group recommends that further work be undertaken to check the appropriateness of the various data inputs used in the catch advice framework for the Faroese fishery, including seeking original datasets from the sampling programmes of the fishery in the historical time period.

4 ) A preliminary proposal for a Framework of Indicators for the NEAC stock complexes was developed in 2011. The Working Group recommends that until alternative management units are agreed by NASCO, this procedure be developed further and that new possible indicators be brought forward to the Working Group for the next assessment in 2012.
5 ) The Working Group noted that the sampling programme conducted in 2010 in Labrador and Saint-Pierre and Miquelon provided biological characteristics of the harvest and that the information may be useful for updating parameters used in the Run Reconstruction Model for North America. This sampling also provides material (tissue samples from scales) to assess the origin of salmon in these fisheries. The Working Group recommends that sampling be continued and expanded if possible in 2011 and future years. As well, scale samples from in-river fisheries (recreational), in Labrador should be collected to determine the river age distributions of the salmon populations not currently being monitored by the limited assessment facilities in Labrador.

6 ) The Working Group supports the proposal from the Greenlandic authorities for the introduction of a logbook as a condition of the licensing system for the salmon fishery at West Greenland.

7 ) The Working Group recommends a continuation and expansion of the broad geographic sampling programme (multiple NAFO divisions) to more accurately estimate continent of origin and biological characteristics of the salmon in the West Greenland mixed-stock fishery.
8 ) The Working Group recommends that SALSEA West Greenland be conducted in 2011 for a third year and that efforts continue to integrate the results from this sampling programme with results obtained from both SALSEA-Merge and SALSEA North America.

9 ) In support of the management objective from NASCO to ensure that individual river stocks meet their conservation limits, the Working Group recommends that additional monitoring data or analyses of existing monitoring data (catches, juvenile surveys, short-term count data), be considered to augment the river-specific data used to develop the stock status and to improve management advice in both NAC and NEAC areas.

## Annex 9: Response of WGNAS 2011 to Technical Minutes of the Review Group (ICES 2010b)

As per the request of the ICES Review Group (RG) this section is the response of the Working Group North Atlantic Salmon (WGNAS) to the Technical Minutes of the RG provided in Annex 7 of ICES (2010b). The comments are presented by subject area or section of the report. Where appropriate, the specific comment(s) from the RG is provided between quotations in italicized text.
"The RG notes ... that the WG should strive to agree on a consistent way of presenting graphical data. Some graphics utilized an axis style that has tick marks that indicate the location of a datum, while other graphs had tick marks that marked the space between data. This shifting style proved to be confusing."

With a diverse range of software being used to generate graphs (Excel®, R®, and others), it is not easy to standardize the look of the outputs. Some information is more amenable to presentation as graphs with tick marks on the datum whereas others, boxplots in particular in some packages, have by default tick marks in the spaces. Where the option exists, the WGNAS has endeavoured to use consistent graphs and axes formats.

## Section 3.5.1 Grouping of national stocks from ICES 2010b

The RG identified the important consideration for the grouping of stocks within the stock complex and this issue is important in the development of the advice framework for the Faroe Islands. Work leading to the development of jurisdiction disaggregated forecast models is ongoing, in recognition of the differences in stock status among regions and to facilitate the research on environmental and biological factors which may be conditioning survival in freshwater, survival at sea, and inter-regional differences in biological characteristics.

## Section 4.4.6 Exploitation rates from ICES 2010b

The exploitation rates table was corrected.

## Section 5.1.1 Catch and effort in 2009 from ICES 2010b

Done.

## Section 5.1.2 Biological characteristics of the catches from ICES 2010b

The RG commented on the adjustment of the West Greenland harvests based on the larger number of fish sampled than is subsequently reported by the fishers at West Greenland and the RG was concerned about putting science staff at risk in these situations. It should be noted that the discrepancy between the observed fish by the samplers and the underreporting from a specific location is not noted during the time of sampling but rather after the fishery when collating the statistics. At no time have any samplers reported being in an adversarial position with the people at West Greenland. In fact, the people of West Greenland have generally been accommodating and courteous to the samplers.

The remainder of the comments of the RG are related to the forecast modelling for generating multiyear catch advice. As indicated by the RG, the models developed and used by the WG are similar for NAC and NEAC. The RG had two main points of concern and the response will be organized accordingly.
"There are two main points of concern in regard to the development of these models: 1) the manner in which spawning stock size is applied in the model; and 2) the lack of progress in developing a predictive capability that includes an environmental driver related to marine survival."
"The provision of forecasted advice is both a pragmatic and mechanistic process. Forecast drivers may prove to be competent in producing a robust statistical forecast, but if the mechanistic underpinnings of the driver variables are not understood, the forecast has a greater risk of becoming inaccurate. Because the processes related to recruitment in Atlantic salmon are conservative and autocorrelated, the current model would appear to be adequate for the provision of advice, but the RG encourages the WG to consider alternate strategies of including the spawner driver in the models."

The RG commented on the form in which spawning-stock and recruitment are structured in the model. As indicated by the RG, there is clear evidence of Atlantic salmon that the recruitment dynamic in freshwater is compensatory and the response can be quite strong depending upon the characteristics of the habitat and the steepness of the survival function at low spawning-stock (and unrelated to whether it is Beverton and Holt, Ricker, or power function; Chaput et al., 1998; Crozier et al., 2003; Michielsens and McAllister, 2004; Gibson et al., 2008). In the present circumstance of modelling spawning-stock and recruitment at a high level of stock aggregation, the variations in freshwater recruitment (smolts) from regional variations in spawningstock are lost. The spawner abundances in the southern regions of NAC and in the southern NEAC area have declined substantially over the period of assessment and in these areas, freshwater production would be expected to respond to variations in spawner abundance. Spatially disaggregated models as currently being explored by the WG would provide an opportunity to more properly describe this densitydependent dynamic between spawners and recruitment. At some point in the development of these region-disaggregated models the WG should consider an alternate parameterization to the proportional relationship currently applied for the regional spawner variable.
"The RG raises the concern that lagged spawned may be a function of recruitment after the post-smolt year, which would be opposite to the manner in which the quantity is applied in the models used by the WG. If this were the case, the reason the lagged spawner variable works in the currently configured forecast models is that since they are both a function of environmental conditions that are autocorrelated on a decadal scale, they remain correlated over the period they are lagged in the model. This possibility needs to be investigated by the WG."

The WG does not understand this statement. Spawners are contingent on recruitment after exploitation in fisheries. In the earlier portion of the time-series for NAC (up to the 1992 PFA year and prior to the Atlantic salmon commercial fishery moratorium in Newfoundland and the large reductions in harvest at West Greenland), spawners and recruitment were not correlated because of the extensive fisheries exploitation which occurred between PFA and the spawning escapement the next year (Figure 9.1). As fisheries closed, an increasingly important component of the PFA recruitment survived to spawners, and the PFA reconstructed recruitment and spawners were strongly correlated. It should come as no surprise that the recruitment to spawner relationship is strong, particularly after the post-smolt year as mortality is assumed to be independent of density and assumed to be unchanged over the time-series. The spawner to recruitment function should however be expected to be statistically weaker because of the multiple points in the life cycle when mortality can vary not only with density but independently with environmental factors acting at different
points and times in the life cycle. This relationship between recruitment which gives spawners and then spawners giving recruitment is an underlying dynamic in all natural resource models and not a misrepresentation of the functional relationship.
"The RG agrees with the WG on the desirability of including environmental information as a driver of the marine productivity parameters of the forecast models. However, this agreement does not ameliorate the lack of progress in this area or the critical nature of the issue in evaluating the state of salmon resources in the North Atlantic."

The WG is tasked with terms of reference submitted by NASCO which include documenting catches, fisheries performances, status of stocks and preparation of multiyear catch advice. The variable status of Atlantic salmon stocks among the regions in the North Atlantic is well documented in the report. The forecast models which have been developed to date are effective at providing catch advice to management, and none of the models have yet to predict abundance of salmon that was outside the realized abundances. The absence of forecast models that consider environmental drivers of productivity in the marine and freshwater environments in the recent and current WG modelling efforts reflects the current state of data availability and modelling opportunities rather than a neglect on the part of the WG members. The forecast models as currently used by the WG do not address cause and effect associations. However, the recruitment dynamic which is characterized by the productivity parameter and in the NEAC model, the proportion maturing parameters, opens the door to the examination of linkages to possible explanatory drivers in freshwater and/or marine, physical and/or biological.
"The RG recommends that ICES encourage national parties to support the WG in this work by providing resources and expertise to advance this work in the salmon assessments. The RG suggests that WG member explore options for participation in other working groups at ICES as a vehicle to expand the available expertise and skill set of the WG. Further, the RG recommends that ICES consider how allied expert groups within the ICES structure may constructively assist the WG in the specialized areas of expertise lacking in the constitution of the WG."

Participation at the WG is open to all interested contributors from the scientific community. Individuals with an interest in contributing to the development of stock status and provision of catch advice as per the terms of reference from NASCO have participated in the previous meetings and are encouraged to do so. The WG has progressed far in its capacity to provide catch advice using risk analysis frameworks that include uncertainties in the input data and the process dynamics, in conformity with assessments and advice models used in other assessment working groups and science advisory bodies. Scientific experts from outside the immediate national nominated delegates of the WG have contributed to numerous initiatives to address specific questions of interest to the WG, including three workshops on the analysis of tagging data and associations with environmental variables (ICES 2007; ICES 2008; ICES 2009b), the Study Groups on the Identification of Biological Characteristics for use as Predictors of Salmon Abundance (SGBICEPS) (ICES 2009a, 2010a), and the Study Groups on assessment and forecast models (SGSSAFE, see Section 2.5). Outside ICES and NASCO, there is a large amount of effort that has been expended to address Atlantic salmon ecology and marine dynamics including numerous special publications on Atlantic salmon (see for example Hansen and Quinn, 1998), special conferences and publications (Mills, 1993; Mills, 1998; Prévost and Chaput, 2001; Crozier et al., 2003) and more are ongoing including the SALSEA projects (see ICES 2010b), and recent multidisciplinary activities including ECOKNOWS.

- Working Group on North Atlantic Salmon (WGNAS)

## General comments

The Working Group continues to produce an excellent assessment of Atlantic salmon populations in the North Atlantic, while at the same time advancing the methodologies used in the assessment of populations of species with short lifespans, especially those with a heavy dependence on environmental effects. These approaches should be of utility to other researchers working within the ICES community and worldwide as well. Our concerns continue to be with the mechanistic underpinnings of the forecast model used to estimate stock abundances in both North America and Europe. These concerns center on the issue of representing stock effects on recruitment as a compensatory function and adding environmental indices to model the effects of environment on post-smolt survival. Both of these concepts can be supported with data presented in the WG report and from the peer review literature. The RG is concerned that the WG needs additional time and flexibility in respect to its workload to make progress on critical issues related to model extensions to reflect the effect of climate variation on salmon stocks.

## Section 2.3.4-Recent results from acoustic tracking investigations in Canada

These research findings speak to the mechanistic processes at work in shaping the recruitment of Atlantic salmon in North America. As reported by Friedland et al. (2003) and recently reexamined by Friedland et al. (in press), recruitment variability is associated with spring, inshore temperature conditions. Because recruitment variability is not associated with variation in post-smolt growth (i.e. the Miramichi River, a Gulf stock, Friedland et al., 2009), it could be attributed to variations in predation rate governed by shifting predator densities. These changes in predator densities would most likely be associated with distributional changes related to warming conditions along the coast. The new data presented to the Working Group in this section suggests that most of the marine mortality affecting Gulf stocks occurs during the first month at sea, within the confines of the Gulf itself and before smolts exit the Strait of Belle Ilse. These sorts of process studies can be used to develop and justify an environmental variable for use in inference and forecast modelling.

## Section 2.3.5-Assessing the impact of common assessment procedures on smolt physiology, behaviour and adult return rates

This section is not consistently supported with reference citations; it would be desirable for the reader to be able to find the source information for these results.

## Section 2.5-NASCO has asked ICES to further develop approaches to forecast pre-fishery abundance for North American and European stocks with measures of uncertainty

It is stated: A preliminary examination of this assumption could be done by comparing the variation in the proportion maturing parameter with the corresponding proportions of the lagged eggs contributed by one of the sea age groups of the spawners.

This is a worthwhile exercise, but it should be approached with caution. Variation in marine survival has been related to geography with the greater erosion in survival rates being experienced by southern tier stocks in both North America and Europe. The maturation rate associated with stocks is also related to geography and assumed to reflect stock genetics and environment. The shift in survival conditions may overwhelm any conservative genetic trait related to maturation, precluding the test the Working Group describes.

It is stated: The factors vary between NAC and NEAC and even within areas of NEAC. Progress on this term of reference would require the development of models at scales below the stock complex level.

It is becoming increasingly clear that model development may have to be conducted below the stock complex level. It is disappointing that the study group was unable to make any progress on this issue considering the importance of understanding these processes on the continued persistence of Atlantic salmon in continental subregions. It is encouraging that further work on this topic will be conducted by the EU project "Effective Use of Ecosystem and Biological Knowledge in Fisheries", which is welcomed and will be of benefit to the tasks of the Working Group, but the expertise to implement these sorts of data analyses and modelling needs to be developed and applied within the Working Group as well.

## Section 3.6.1-Description of the forecast model

The WG acknowledged the desirability and the difficulties of incorporating compensatory stock-recruitment relationships in the modelling of both North American and European salmon populations at the stock complex levels. At issue is the use of a proportional relationship between lagged eggs and PFA and the conclusion that PFA abundance will respond directly and predictably with changes in lagged eggs. This assumes that freshwater production is below carrying capacity. This has not been demonstrated for these stocks, in fact spawners in NEAC have been at or above the conservation limits over most of the time-series and the expectation should be that at these levels of spawners, smolt production should not have been variable. A nuance of one of the stock indicator time-series stimulated discussion in the RG. The case in point was the estimate of smolt production from one of the most important NE Atlantic index rivers, the North Esk in Scotland. The figure below (Figure 1) provides an estimate of the population of migrating smolts from the Esk by year (J. MacLean, personal communication). Smolts are captured at a trap situated on a lade that runs off the main river ca. 7 km from the sea and rejoins the river ca. 2 km from the sea. A mark release and recapture experiment is used to estimate the total smolt production from the river.

Figure 1. Time-series of North Esk smolt migration estimates with $95 \%$ CI, smoothing line in 10 point adjacent average.

For the assumed SR relationship attributed to lagged eggs to be true, the recruitment pattern would have to be reflected in the production of smolts. The spawner escapement data that produced these smolts were not available in the WG report. But the lagged eggs for the southern NEAC stock corresponding to this smolt production period have varied by half, and declined over the time period. The fact that the estimated smolt production has not declined suggests that the SR function in freshwater is more likely defined by a compensatory function (Ricker or Beverton-Holt for example) and the balance of the recruitment pattern is defined by the marine survival of post-smolts. The RG encourages the WG to consider this and other data in the context of what they suggest about the recruitment process and how it may guide the development of model variants. The RG suggests that taking an ensemble approach to model formulation may be a useful and instructive exercise for the WG because there are still significant gaps in our knowledge of salmon population dynamics. The way forward proposed by the WG is to model the spawner and recruitment dynamic at subregional scales which would provide an opportunity for the compensatory form of the $S R$ relationship to be inferred from the region specific data. A multi region $S R$ model could be developed which would provide a mean stock and recruitment function for a large complex and an example of this was provided by the RG. The solution to the multi-region SR functions is obtained from the Taylor expansion of the Ricker equation:

$$
a E e^{-b \mathrm{E}}+\sigma_{b}^{2}\left(\frac{1}{2} a E^{3} e^{-b \mathrm{E}}\right)+\left(-\mathrm{ab} e^{-b \mathrm{E}}+\frac{1}{2} a \mathrm{~b}^{2} E e^{-\mathrm{b} \mathrm{E}}\right) \sigma_{\mathrm{E}}^{2}
$$

where $a$ and $b$ are parameters in the simple version of the Ricker function, $\sigma^{2} b$ denote the variance of the parameter $b$, and $E$ corresponds to the expected number of eggs. The variance of the total number of eggs $\left(\sigma^{2} \mathrm{E}\right)$ is most likely not a constant but will rather vary with the total egg numbers. One simple assumption about such change in variance would be to use the coefficient of variation (CV), i.e. $\sigma^{2} E=\left(C V^{*} E\right)^{2}$. The covariance and higher-order components have been left out from the above equation.

The RG appreciates the difficulty to incorporate environmental data into the stock complex level models. The demands of the routine assessment activities and the lack of capability to deal with these types of data at the WG are real problems; the RG hopes to contribute to a strategy to find a solution to these problems. The RG considered a worked example of how forcing variables may be identified. An easily acces-
sible independent variable to represent the marine survival process is SST, though SST is most likely a proxy for a shift in primary and secondary productive changes that have occurred in the Northeast Atlantic. From Friedland et al. (2009a), the August SST field yielded the strongest correlates that overlap the summer post-smolt nursery area described by Holm et al. (2000). The following figure is the relationship between S-NEAC non-maturing PFA and SST from the ERSST dataset (Smith et al., 2008) for the location $14^{\circ} \mathrm{E} 74^{\circ} \mathrm{N}$ (Figure 2).

Figure 2. Relationship between Southern NEAC Non-maturing PFA and Northeast Atlantic SST for $14^{\circ} \mathrm{E} 74^{\circ} \mathrm{N}$ during August of the post-smolt year.

Little effort was put into optimizing this environmental correlate; a better fit may be achieved by doing an EOF (principal components) on the SST and looking at indices constructed from data from multiple months. This would seem to provide a means to either explicitly add a forcing variable or calibrate a survival rate function believed to vary with temperature conditions. As variations in SST may be a proxy for factors that modify marine survival, the SST data or other environmental forcing variable would be expected to modify the recruitment rate parameter, as currently modelled by the WG, lagging for the period corresponding to the post-smolt summer at sea. The importance of studying this aspect of recruitment can be put into perspective by looking at the long-term time-series of SST from this location. As typical of the Norwegian Sea and surrounding areas, and not just for August, SST is at record high levels, with 2010 (last point in time-series of the graph below) being the highest in the temperature record (Figure 3).

Figure 3. Northeast Atlantic SST for $14^{\circ} \mathrm{E} 74^{\circ} \mathrm{N}$ during August for the period 1854 to 2010.

The expectation of further increases in ocean temperature makes interfacing stock dynamics and the environment that much more critical (Stock et al., 2011).

So to reiterate, the RG suggests that the WG consider a review of how the stock parameter is applied in the inference and forecast model; and, that productivity be modelled with a covariate variable(s) that have been proposed to describe the mechanistic underpinnings of the effect of environment on marine survival of postsmolt salmon. The RG believes that moving the assessment in this direction would make the model more responsive to contemporary fisheries issues and also make it more relevant to the issue of persistence of Atlantic salmon in a climate and ecosystem change context.

## Section 3.7.1-Changes to the NEAC PFA model and national conservation limit model

The WG is encouraged to attempt to re-evaluate the 1971-1982 data for Norway to see if a parsimonious solution can be found to provide PFA estimates for that time period. Moving to the subcomplex scale provides an opportunity to incorporate the longer time-series in the other jurisdictions, without waiting on the extension of the dataset for Norway.

## Section 4.5.6-Pre-fisheries abundance

The WG is using the same model form as used in the NEAC to model NAC PFA. Here again, the RG encourages exploration of different SR forms for the modelling work (as described in RG comments of Section 3.6.1). For NAC, the RG discussed the important insights provided by the time-series of smolt production from two Quebec Rivers (Figure 4.5.1.1). Smolt production has declined in the St Jean and de la Trinite rivers for a period beginning in the middle 1980s; at the same time escapement of 2SW fish were at conservation limits up until the middle 1980s and declined below CLs since, thus the decline in smolts could be attributed to the deficit in spawners (Figure 4.5.2.3). Unlike the example for the NEAC provided by the data for the North Esk and the lagged eggs for the S-NEAC complex, there is no data for a period of escapement exceeding CL to match with smolt production, but it is difficult to see why the SR dynamic in North American rivers should respond differently. These data underscore the importance of the form used for modelling the stock component in the forecast model and reinforces the CL concept for salmon.

Drawing on recent information described above, a putative environmental variable was selected to link with the time-series variation in PFA of the North American stocks (SST from June in a location associated with coastal post-smolt habitats, $66^{\circ} \mathrm{W}$ $50^{\circ} \mathrm{N}$ ). This SST time-series provides a candidate independent variable to forecast North American PFA (Figure 4).

Figure 4. Relationship between NAC Non-maturing PFA and Northwest Atlantic SST for $66^{\circ} \mathrm{W}$ $50^{\circ} \mathrm{N}$ during June of the post-smolt year.

No effort was made to optimize the SST variable, so as suggested in the NEAC comments above, the potential to improve the index exists. As with the key habitat location highlighted in the NEAC comments, this area in North America is also experiencing extreme thermal conditions; though 2010 was not the highest observation in the time-series, it was among the highest and is representative of a trend of extreme warming occurring in this part of North America (Figure 5).

Figure 5. Northwest Atlantic SST for $66^{\circ} \mathrm{W} 50^{\circ} \mathrm{N}$ during June for the period 1854 to 2010.

So to reiterate, the RG suggests that the WG examine the manner it represents SR in the forecast model and consider exploring the incorporation of physical forcing in the model that reflects the state of our knowledge of the mechanistic underpinnings of the effect of environment on marine survival of post-smolt salmon.

## Section 4.6-Summary on status of stocks

Stated: The continued low abundance of salmon stocks across North America, despite significant fishery reductions, further strengthens the conclusions that factors other than fisheries are constraining production.

The WG could try to be more specific as to what is going on with the stocks. It is widely accepted that marine mortality has increased and there is evidence to support mechanistic explanations.

## Section 5.1.1-Catch and effort in 2010

Logbooks can be a source of information or a source of misinformation. It is critical that the fishers understand the intended use of the logbook data to ensure the best and most accurate data be available.

## Recommendation from the Review Groups to be considered by ACOM

The RG recommends that ICES develop a SG process to focus on how environmental forcing may be incorporated into salmon assessments and how these data may be made operational for use by the WG. This RG appreciates that there are parallel concerns on this matter in respect to Baltic salmon (WGBAST).
