## REPORT OF THE WORKING GROUP ON FISH STOCKS AT THE FAROES

Charlottenlund, 6-10 February 1978

This Report has not yet been approved by the International Council for the Exploration of the Sea; it has therefore at present the status of an internal document and does not represent advice given on behalf of the Council. The proviso that it shall not be cited without the consent of the Council should be strictly observed.

V Nikolaev，ICES Statistician，also participated in the meeting。

2．INTRODUCTION
2.1 Terms of Reference

At the 65th Statutory Meeting it was decided（C．Res．1977／2：19）that the Working Group on Fish Stocks at the Faroes should meet at Charlottenlund during 6－10 February 1978 to：
（a）assess TACs for 1979 for cod and haddock，
（b）further assess the effective mesh sizes in current use，and to estimate the effects of further increases in mesh size for these species，
（c）plan and discuss the design of the International 0－Group Survey at the Faroes in 1978，
（d）identify and specify in detail，shortcomings and gaps in the data required for stock assessment work，
（e）review and update data in the＂Review of Fish Resources＂ given in the Appendix to the 1977 Working Group Report．

## 2．2 Management Changes and Changes in the Fishing Pattern around the Faroes

The＂Arrangement Relating to Fisheries in Waters Surrounding the Faroes＂was terminated in early 1977 and since then fishing by countries other than Faroes has been subject to quotas permitted by the Faroese authorities，and in addition access to certain fishing grounds has been restricted．On 1 January 1978 the minimum trawl cod－end mesh size was increased from 120 mm （synthetic）to 135 mm （irrespective of material）．
Tables 13 and 14 show the changes in landings of cod（Faroe Plateau） and haddock（Total Div。Vb）by the various gearso It is clear that during the last four years the proportion of the catch of both species taken by longline has been increased substantially while the proportion taken by trawl has declined。 Fishing effort by the United Kingdom trawlers in 1977 was reduced to about $60 \%$ of the level in 1975－76。

3．THE STATE OF THE STOCKS
3．1 Cod（Plateau Stock）
3．1．1 Trends in catch and effort
As in previous years the assessment has been made only for the Faroe Plateau cod stocks as data for the Faroe Bank are not sufficiently grood for a separate assessment to be made for that stock．

Data on landings have been updated．Fstimatedelandings of cod from the Faroe Plateau in 1977 were 35000 tons compared with 39917 tons in 1976．The equivalent figures for the total Division Vb were 36000 tons （1977）and 42129 tons（1976）（Table 1）。 Catches by Faroese vessels in 1977 were maintained at the same level as in 1976 （29 000 tons） but the landings by other countries，particularly by the United Kingdom，were appreciably lower in 1977 （7 000 tons in 1977 compared with 13170 tons in 1976）．The recruitment of the abundant 1972 and 1973 year classes has contributed to the high catohes in 1975－77。 High catch per unit effort was recorded for these years by Faroese long liners（Table 25）。

## 3．1．2 Virtual＿population analysis（VPA）

Previous estimates of total numbers landed in each age group in 1976 have been updated and provisional estimates were prepared for 1977. Age composition data for 1977 were available for Faroes，United Kingdom（England）and United Kingdom（Scotland）。 French length compositions were converted to age compositions using the English age／length key。 Landings by other countries were assumed to have the same age distribution as the combined English，Scottish and French landings．

Age compositions of the total catches from the Faroe Plateau used as input data for the VPA are given in Table l5。 Values of fishing mortality coefficients calculated by VPA are given in Table 16 together with the values assumed for 1977 which were used to initiate the computation。 Estimates of stock size as calculated by VPA are given in Table 17.

Recent changes in the fishery have made it more difficult than usual to estimate both the current exploitation pattern and the overall level of fishing mortality in 1977.
Following the extension of Faroese jurisdiction to 200 miles the amount of fishing by non－Faroese vessels has declined，and access to fishing grounds has been restricted．The amount of fishing by long－ liners has been increasing and，especially in the latter part of 1977，increased inspection and enforcement activities are likely to have reduced the incidence of fishing with undersized trawl codmend meshes．All these changes would be expected to affect the overall exploitation pattern and this has been taken into account in the $F$ values for 1977，which were adopted for input into the VPA in which the values for ages 2 and 3 were reduced relative to those on the older ages．

3．1．3 Catch predictions and TACs
In making catch predictions the Group considered that the increase in the minimum trawl codwend mesh size to 135 mm in 1978 would be expected to further affect the exploitation pattern，and accordingly the $F$ values on one－and twongroup fish have been reduced．The data used for the catch predictions are given in Table 22．A consequence of the changed exploitation pattern will be that the yield per recruit curve will be different from that given in the report of the 1977 meeting of the Group．The new yield per recruit curve is given in Figure 1，and on this curve the value of $F_{\max }=0.4$（on fully exploited age groups）。 There is some uncertainty about the size of recent year classes and for the catch predictions average recruitment（ $16 \times 10^{6}$ at age 2）has been used for the 1974 and sub－ sequent year classes．A number of catch predictions were made for differing rates of reduction in the level of fishing mortality．The resultant yield and corresponding spawning stock biomass estimates are given in Table 23.

It seems unlikely that there was any significant reduction in fishing mortality in 1977 and the recorded catch of 35000 tons（Plateau only）was close to the prediction of 34000 tons given in the previous report of the Working Group．The Group reiterates its advice of last year that fishing mortality on cod should be reduced to the $F_{\max }$ level．In the long term the main benefit would be from increased catch rates because the yield per recruit would be expected to increase only marginally。 Spawning stock size would also be larger at a reduced level of fishing mortality，but there is no indication at present that the spawning stock size is being unduly reduced． Estimates of the spawning stock biomass at the beginning of a year for 1959－1980 are shown in Figure 5。
The TAC for 1979 would depend on the rate at which the reduction in fishing mortality could be achieved．The Working Group recommends a progressive reduction in fishing mortality to reach $\mathrm{F}_{\max }$ in 1980。 On this basis the following TACs are proposed：

## Recommended TACs for Cod

| Year | F | TAC（including 2 000 tons for <br> Faroe Bank）（in tons） |
| :--- | :---: | :---: |
| 1978 | 0.55 | 32000 |
| 1979 | 0.45 | 27000 |
| 1980 | 0.40 | 26000 （subject to revision） |

This advice follows that given last year with regard to the proposed reduction in fishing mortality If the strategy is followed and it is aimed at achieving an $F=0.55$ in 1978，the corresponding updated TAC is now 32000 tons which is 2000 tons greater than that given in the previous report of the Working Group．This difference results from the changed exploitation pattern used in this report．
If this revised TAC is adopted for 1978 the recommended TAC for 1979 would be 27000 tons．

### 3.2 Haddock

3．2．1 Trends in catch and effort
The provisional catch in 1977 was 25000 tons and this was similar to the catch in 1976．Both catches represent an increase in the catch level over that in the immediately preceding years（Table 2）。
The proportion of the total catch taken by different gears have changed considerably in recent years．For example，over the period 1974－77 the proportion taken by long－liners（mainly Faroese vessels）rose from $25 \%$ to $69 \%$ 。 During the same period，the proportions taken by trawlers （mainly United Kingdom vessels）declined from $74 \%$ to $28 \%$（Table 14）。
Catch per unit effort data for the Faroese long－liners have shown increasing catch rates for the last three years（Table 25）。

3．2．2 Virtual population analysis（VPA）
For the VPA input data（Table 18），the 1976 data were revised and provisional data for 1977 added．Age compositions were available for the Faroese，English and Scottish fisheries．The percentage age composition for other countries（France，Federal Republic of Germany，Netherlands and Norway）were assumed to be the same as that for the English and Scottish fisheries combined．

In choosing input values of $F$ ，different considerations were employed when dealing with the fully exploited age groups（4 years and older）than when dealing with younger fish．
For the fully exploited age groups，trial VPA runs suggested that the previously employed value of $F$ of 0.6 might now be too higho After further trials，a value of 0.5 was selected as appearing more suitable。
For the younger fish（2 and 3 year old）it is appropriate to choose input values of $F$ that are consistent with stock size estimates predicted on the basis of year class strength expectations．For example，Figure 3 shows the relationship between Scottish research vessel estimates of year class strength（as 1 year old fish）and the VPA estimates based on the numbers subsequently appearing as 3 year old fish in the fisheryo Figure 4 shows a similar relation－ ship，but úsing the VPA estimates of year class strength as 2 year olds．Using these relationships it was estimated that in 1977 the 3 year olds（ 1974 year class）should number about 30 million fish． Similarly it was estimated that the 2 year olds（1975 year class） should be about 19 million fisho To＇satisfy these stock estimates， the following $F$ values were calculated：

$$
\begin{aligned}
& F \text { for two year olds in } 1977=0.025 \\
& F \text { for three year olds in } 1977=0.20 .
\end{aligned}
$$

These values are lower than those given in the previous report which is consistent with effects expected from mesh size enforcements in 1977 and increased fishing by longoliners．
Estimates of fishing mortality calculated by VPA are given in Table 19 and calculated stock sizes are given in Table 20。

## 3．2．3 Current state of stock

Haddock landings in 1976 and 1977 were somewhat larger than they had been in the immediately preceding years and various factors may have contributed to this．These include the appearance of 3 good year classes（1972－1974），a possible decline in F values，and a change in exploitation pattern。
The decline in the trawl fishery and the increase in long－line fishery have presumably lea to a change in the exploitation
pattern equivalent to an increase in the age at first capture。 The effect of this should have been the same as an increase in mesh size。

## 3．2．4 Catch predictions and TACs

In the catch predictions，it has been necessary to take account of the following factors：
（a）the introduction of a 135 mm mesh size from l January 1978；
（b）the relative strength of incoming year classes；
（c）management objectives。
The increase in mesh size to 135 mm is expected to change the exploita－ tion pattern by reducing the values of $F$ on the youngest age groups． Estimates of this effect were made using theoretically－derived selection curves and an age／length relationship。

Selection curves were calculated using a selection factor of 304 and adopting slopes of 0.12 at the $50 \%$ pointso An age／length relationship was constructed using $L_{\infty}=83, \mathrm{~K}=0.15$ ，and $t_{0}=-1.6$ 。

It was estimated that with a 135 mm mesh, there should be a negligible catch of 2 year old fish. For 3 year old fish, the value of $F$ should be about 40-50\% of its previous value. On this basis, the value of F for 3 year olds from 1978 onwards was reduced from 0.2 to 0.1 . For the 4 year and older fish, the $F$ values should be unaffected。
The data used for the catch predictions are given in Table 22.
From Scottish research vessel estimates of year class strength, it is expected that both the 1975 and 1976 year classes should be below average. The relationship in Figure 3 was used to calculate the recruitment values of these year classes a 3 year olds in 1978 and 1979. This gave the following values:

For the 1974 year class in 1977: 30 million fish
For the 1975 year class in 1978: 18 million fish
For the 1976 year class in 1979: 12 million fish.
For the prognosis program a value was also needed for the strength of the 1973 year class in 1976. A value of 28 million fish was used which was taken from VPA.
TACs were calculated using two recruitment options. For one option, the estimates of year class strength given above were used. For the other option, an average recruitment value of 26.8 million 3 year olds were adopted for all year classes.
TACs were calculated for two management objectives: to maintain the $F$ values at the 1978 level, and to adopt an $F$ value for the fully exploited age groups equivalent to $F_{\max }$ on the yield per recruit curve. To determine this, yield per recruit curves were calculated, using the exploitation pattern thought to be appropriate for the 135 mm mesh. From this curve (Figure 2), a value of $\mathrm{F}_{\max }$ equal to 0.55 was determined. This is larger than the value of 0.4 previously obtained using the pre-1978 exploitation pattern.
A summary of haddock TACs for the four options is given in Table 24. With a mesh size of 135 mm , the value of $F=0.5$ on the fully exploited age groups is about $10 \%$ below the theoretical $F_{\max }$ value of 0.55 . This means that an increase in fishing effort in 1978 and 1979 of up to $10 \%$ (compared with the 1977 level) could be considered. In that event, the TAC in 1979 could be 1000 tons higher than it would otherwise have to be (i。e., 24000 tons instead of 23000 tons and 21000 tons compared with 20000 tons).

Summary of Haddock TACs (in metric tons)

| Year | $F$ | TAC |
| :---: | :---: | :---: |
| 1978 | 0.55 | 25.000 |
| 1979 | 0.55 | 21.000 |
| 1980 | 0.55 | 17.000 (subject to |
| revision) |  |  |

Allowance for the likelihood of poor recruitment causes the TACs to be reduced by 3000 tons for both options. Although estimates of year class strength from research vessel data tend to be uncertain, the data base appears good enough to suggest that both the 1975 and the 1976 year classes are likely to be below average strength. This factor should therefore be taken into account and it is recommended that the TAC for 1979 should be 21000 tons.

In the previous report of the Working Group a TAC of 17000 tons was recommended for 1978．This was calculated taking into account a reduction in fishing effort（or F）．In the new calculation the revised exploftation pattern was used and as a consequence it was not necessary to reduce fishing mortality．Thus a revised TAC for 1978 is 25000 tons．

4．NESH ASSESSMENTS
Although the 1976 and 1977 length composition data for cod and haddock were at hand at the meeting，the Group was not able in the time available to perform any further mesh assessments．The model used in the mesh assessments last year has now been described．by Hoydal（1977）。 This has explained some things，which did not emerge from last year＇s Working Group report，especially how assumptions on recruitment curves influence the estimates of effective mesh size in operation．Assumptions about recruitment could be important for cod，but probably not for haddock，although haddock assessments could be influenced by discarding。
Further，the Group felt，that in a situation with changing fishery pattern and management measures it would be difficult to make any reliable predictions of the long－term effects of any further changes．
The Group considered that increased enforcement by Faroese authorities in 1977 had probably resulted in the real mesh size being much closer to the legal mesh size than in former years．

5．INTERNATIONAL O－GROUP SURVEYS AT TAR：OES TNX 1978
The French research vessel＂Thalassa＂and the Faroese＂Jo Chro Svabo＂ will take part in the 0－qroup Surveys in Faroe waters this year．It was indicated that＂Thalassa＂will be able to spend 11 days for the $0-$ Group Surveys，expecting to cover about 60 stations in mid－May．It was agreed to select the French stations at random as for the Faroese ones．The French cruise will mainly be aimed at covering O－group saithe，and some comparative experiments between the 0－group gear and the Bongo（or stramin）net will be made，in order to try to determine the size range of O－group saithe。
＂J。Chr。Svabo＂will cover about． 120 stations in late June and early July．The cruise will mainly be aiming at sampling cod and haddock．

6．SHORTCOMINGS AND GAPS IN DATA REQUIRED FOR STOCK ASSESSNENT PURPOSES
It has already been mentioned that the uncertainty about future develop－ ments in the fishery in the Faroe Area pose problems to the assessment work。
For the data，it was noted that because of the increasing part taken by Faroese vessels，any success in the assessment work will depend on adequate Faroese sampling of age and length data。
The Group had difficulty with the lack of reliable recruitment data， especially for cod．Further O－Group Surveys are required in order to assess their value for making recruitment estimates．
Effort data are required from those fisheries for which they are not currently available。

F) Proportion of $F$ relative to $F$ on age groups subject to maximum exploitation.

Recruitment (at age 2)
Recruitment of $16 \times 10^{-6}$ assumed for year classes after 1974.

For assumptions on recruitment, see text.

Table 23. Catch and spawning biomass predictions. Natural mortality $=0.2$.

Faroe cod

| Year | $F$ | Yield ${ }^{\text {\# }}$ ) | Spawning biomass |
