# REPORT OF THE NORTH SEA ROUNDFISH WORKING GROUP <br> Charlottenlund, 3-7April 1978 

This Report has not yet been approved by the International Council for the Exploration of the Sea; it has therefore at present the status of an internal document and does not represent advice given on behalf of the Council. The proviso that it shall not be cited without the consent of the Council should be strictly observed.

2．TERMS OF REFERENCE
At the 1977 Statutory Meeting of ICES in Reykjavik，it was decided （C．Res．1977／2：22）that：
＂the North Sea Roundfish Working Group should meet at Charlottenlund 3－7 April 1978 to：
（a）determine year class strengths for cod，haddock and whiting from data collected from the International North Sea Young Herring Surveys，
（b）assess TACs for 1979 for cod，haddock and whiting in Sub－areas IV，VI and VII（excluding Divisions VIIa and VIIf），
（c）report on the effect of increases in mesh size for these species in Sub－area VI，
（d）identify and specify in detail shortcomings and gaps in data required for stock assessment work，
（e）review and update the＂Review of Fish Resources＂ given in the Appendix to the 1977 Working Group Report＂。

At the request of the Chairman of the Advisory Committee on Fishery Management（ACFM），the Working Group also considered：
（f）the applicability of a mesh assessment largely based on Division IVa data，to other parts of Region 2， with particular reference to whiting in the eastern English Channel，
（g）appropriate minimum landing sizes in relation to proposed mesh changes，and
（h）the calculation of TACs for Division IIIa。

## 3．TOTAL ALLOWABLE CATCHES（TACs）

3．1 Recommended TACs
Recommended TACs for 1979 are summarised below for various options． TACs for 1979 （in 1000 metric tons）

| Sub－area | Option | Cod | Haddock | Whiting |
| :---: | :---: | :---: | :---: | :---: |
| IV | I | 190 | 85 | 96 |
|  | II | 175 | 80 | 75 |
|  | III | 165 | 78 | - |
| VI | IV | 155 | 75 | - |
|  | II | 14 | 11 | 12 |
| VII＊ | 14 | 11 | 5.5 |  |
| Div．IIIa |  | 6.1 | 5.9 | 14 |

＊excluding Divisions VIIa and VIIf。
In Options I and II，it is assumed that $F$ values in 1978 remain at the same level as in 1977。

Option I gives the recommended TACs for 1979 if there is no change in mesh size in 1979。
Option II gives the recommended TACs for 1979 if there is an increase in mesh size to 90 mm in 1979。

Options III and IV have been included to allow for the possibility that F values in 1978 may be influenced by TACs set for $1978{ }^{*}{ }^{*}$ 。
For example，for cod the $F$ values in 1978 would have to increase by about $20 \%$ to just take up the 1978 TAC of 236000 tons．For whiting F values have to increase by about $100 \%$ ．For haddock $F$ values would have to decrease by about 20\％。 Option III gives the recommended TACs for 1979 if the $F 1978$ values are adjusted in this way，and if there is no change in mesh size in 1979。
Option IV gives the recommended TACs for 1979 in the comparable situation，but assuming that there is an increase of mesh size to 90 mm in 1979。

Options III and IV have been calculated for cod and haddock but not for whiting。
Catch predictions for these and further options are given in Tables 5．l．A and 5．l．B．Recommended values were selected from the options in these tables with the object of reducing $F$ values in 1979 below their levels in 1977.

For haddock（Options III and IV）the recommended TACs for 1979 were chosen so as to keep $F$ values in 1979 the same as those in 1978 （ioeo， $20 \%$ below the 1977 levels）。

For haddock in Options I and II，and for all options for other species， the recommended values were chosen so as to make $F$ values in $197910 \%$ below the 1977 values．

[^1]For haddock and whiting，the predictions in the tables for both landings and（in brackets）catches are given．The recommended TACs for these two species are based on predictions of landings，rather than catches．

Because of uncertainties in selection factors，the assessments，in which an increase in mesh size was allowed for，were made for a range of selection factors for each species．Values for high and low selection factors are given separately in Tables 5．1．A and 5。1。B． The recommended TACs are based on averages of the values obtained for high and low selection factors in each instance。
For stocks in Divisions IIIa，VIb and Submarea VII（excluding Divisions VIIa，f）TACs were determined on the basis of average landings．The values obtained for Division VIb in this way have been included in the TACs for Sub－area VI given above。

## 3．2 Stocks in Division IIIa

There is a certain amount of interchange between the stocks of cod， haddock and whiting in the North Sea，and those in Division IIIa。 It would be appropriate therefore to include a component of the Division IIIa landings along with the TAC for Sub－area IV。

Unfortunately，the reported landings from Division IIIa include landings from various zones，and the necessary data for separating the different components of the landings are not available。
The Group is therefore unable to recommend a TAC for that component of the Division IIIa stock，that，on biological grounds，should be included with Sub－area IV。 A TAC for the whole of Division IIIa has been given，based on the reported landings statisticso

3．3 Management of Roundfish Stocks by Catch Quotas
The Working Group wishes to draw attention to the difficulty of con－ trolling fishing mortality by means of catch quotas．
l．Due to the high rates of exploitation in the stocks considered in this report，the recruitig year classes make up a large proportion of an exploitable stock．Consequently，estimates of year class strength are an essential part of a catch predictiono

Accurate catch predictions are impossible if average year class strengths have to be assumed．The high exploitation rate also increases the errors in extrapolation。
The combination of these effects means that estimated TACs will vary considerably about their true values．Moreover，due to the small number of year classes in the fishery，the true value of a TAC will vary considerably from year to year．Pope and Garrod （1973）discuss this problem and point out that both problems may be reduced by the adoption of lower exploitation rates．The precision of estimation can also be increased by the provision of better data and，more importantly，by reducing the time period for which extrapolations have to be made。 At present the 1979 TAC has to be estimated from 1977 data。
Due to these problems the TACs estimated by the Working Group will inevitably have a considerable variability about their true value and consequently they can only provide approximate manage－ ment advice。

2．Management of fish stocks by catch quotas is aimed at control of the rate of fishing mortalityo To achieve this，it is necessary to control the catch，wheras，in practice，it is only possible to
control the landings. With the present mesh size large amounts of roưndfish are discarded at sea. The proportion of fish discarded can in fact be so large, that there is little hope that controls placed on landings are likely to be effective at restricting catches. It is possible that in some instances, TACs are more effective at influencing rates of discarding than catches.

It seems unlikely therefore that TACs can present a satisfactory solution to the problem of managing fishing effort on roundfish stock, unless : some means, such as higher mesh sizes, are found for greatly reducing the rates of discarding.
4. STATE OF EXPLOITATION

It is difficult to quantify the state of exploitation of cod, haddock and whiting stocks in Sub-areas IV, VI and VII. This is because criteria based on different asumptions lead to views that cannot easily be reconciled:

1) For some species, $F$ values are greatly in excess of $F_{\text {max }}$ values on yield per recruit curves. According to this criterion, a number of the stocks under consideration are all seriously overexploited (Figures 1-3).
2) Yield per recruit curves are not necessarily the same as total yield curves however. It is therefore not certain to what extent changes in total yield would necessarily be the same as changes in yield per recruit, for changes in fishing mortality.
3) During the 1960s, the stocks of cod, haddock and whiting in some areas and particularly in the North Sea and Division VIa increased significantly above their pre-1960 levels. This was a consequence of good recruitment, and it is not known to what extent this, and other changes that took place in North Sea fish stocks at the time, were the result of natural processes or to what extent they were an indirect outcome of fishing.

Although there are these difficulties in evaluating the state of exploitation of these stocks, it is recommended, on the basis of yield per recruit considerations, that fishing mortality should be reduced, and that reductions in effort should be made in small steps. This should lead to gains in both yield per recruit and also spawning stock biomass (Figures $1-3$ and Figure 7).

## 5. MESH ASSESSMENTS

Assessments, using the method of Gulland (1961), have been made on the effects on yield per recruit of changes in mesh size in Divisions VIa and VIId.

### 5.1 Division VIa

Assessments were made of the long-term effects on yields/recruit of the adoption of 80 and 90 mm mesh sizes for cod, haddock and whiting in Div.VIa. Input data are shown in Tables 7.1-7.3 and 7.6-7.8. Overall results were as follows:

| Species | Average catch <br> $1970-76$ (tons) | Long-term gains 1) |  |
| :--- | :---: | :---: | :---: |
|  | 80 mm |  | 90 mm |
| Cod | 13504 | $0 \%$ to $2 \%$ | $0 \%$ to $4 \%$ |
| Haddock | 28680 | $0.4 \%$ to $2 \%$ | $2 \%$ to $6 \%$ |
| Whiting | 17206 | $2 \%$ to $2 \%$ | $3 \%$ to $5 \%$ |

1) Range of values allows for range of selection factors.

More detailed results giving the gains and losses for national fleets shown in Tables 7.11 to 7.13. From the available data, long-term benefits using a 90 mm mesh size should be negligible, but the inclusion of data on discard, which were not available for these assessments, could alter this conclusion. Because of lack of data, the gains shown above can be regarded as underestimates of the likely long-term gains.

### 5.2 Division VIId

Assessments of the effect on yield/recruit of the adoption of 80 mm and 90 mm mesh sizes were made for cod and whiting in Division VIId. Input data are shown in Tables 7.4-7.5 and 7.9.-7.10. As for the Division VIa assessments, calculations were done for a range of selection factors. Overall results were as follows:

| Species | Average catch <br> $1970-76$ (VIId,e) (tons) |  | Long-term gains1) |  |
| :--- | :---: | :--- | :---: | :---: |
|  |  | 80 mm | 90 mm |  |
| Cod | 3641 | $0 \%$ to $4 \%$ | $0 \%$ to $10 \%$ |  |
| Whiting | 6819 | $8 \%$ to $12 \%$ | $15 \%$ to $19 \%$ |  |

1) Range of values allows for range of selection factors.

More detailed results giving the gains and losses for national fleets are shown in Tables 7.14 - 7.15 ( 90 mm only).
For both species, the introduction of 80 mm or 90 mm mesh sizes should lead to long-term gains even though some are not large.

### 5.3 General Comments on Mesh Size Increases

An increase in mesh size would appear to be particularly appropriate in fisheries in which extensive discarding is common practice.
Attention is drawn to the relatively large immediate losses for some species in some areas. Large short-term losses may be undesirable, and for this reason it may be appropriate to allow the rate of increase in mesh size to be more gradual in areas where the immediate losses would otherwise be unacceptably large.

6．SHORTCOMINGS AND GAPS IN DATA REQUIRED FOR STOCK ASSESSMENT PURPOSES
6．1 Age Composition Data
Age composition data are still not collected，or not adequately collected， by some countries．
The following text table indicates the percentages of the total inter－ national landings for which there are national sampling programmes providing age composition data。

| Area | COD |  | HADDOCK |  | WHITING |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | I | $\mathrm{D}^{*}$ | I | $D^{*}$ | L | D＊ |
| $\begin{array}{rr} \text { Sub-area IV } 1976 \\ 1977 \end{array}$ | $\begin{aligned} & 84 \\ & 88 \end{aligned}$ | $\begin{aligned} & 10 \\ & 17 \end{aligned}$ | $\begin{aligned} & 69 \\ & 80 \end{aligned}$ | $\begin{aligned} & 60 \\ & 78 \end{aligned}$ | $\begin{aligned} & 85 \\ & 91 \end{aligned}$ | $\begin{aligned} & 59 \\ & 60 \end{aligned}$ |

| ```Div。IIIa Div.VVIIa:-e,g-k Div.VIb``` | + 0 0 | $\begin{aligned} & 0 \\ & 0 \\ & 0 \end{aligned}$ | + 0 0 | $\begin{aligned} & 0 \\ & 0 \\ & 0 \end{aligned}$ | + 0 Inc Di |  |

$\mathrm{L}=$ Landings．
$D=$ Discards．
＊）\％of consumption fishery covered．

In some areas（e．g．，Divisions IIIa，VIIb，c，g－k）few，if any，age composition data are collected．

## 6．2 Year Class Strength

Recruitment surveys are needed in Sub－areas VI and VII。

## 6．3 Selectivity Data

Selectivity data available for the assessment group are based on experiments carried out some time ago．Information is now needed to take account of modern fishing practice，in which towing speeds may be higher than they used to be。

## 6．4 Effort Data

Reliable indices of fishing effort are required for all countries and fleets．

7．MINIMUM LANDING SIZES
The Working Group has considered the basis for relating minimum landing size to mesh size。 This request has arisen from a suggestion that by making the minimum landing size correspond to something less than the $50 \%$ reten－ tion size of the mesh size in use，wastage of fish due to discarding could be reduced．

## 7．1 Need for a Minimum Landing Size

In the Recommendation 4 fishery a minimum landing size is intended to help the enforcement of a mesh size。 The intention is that fishermen should be discouraged from using too small meshes，because of the wastage caused by having to discard the undersized part of the catcho
If a minimum landing size is to be effective，it is，therefore，unavoidable that some wastage of fish should have to occur．This waste should be regarded as a cost to be offset against the benefit expected from a more effective enforcement of the mesh size。

It follows that：
I）If a mesh size could be effectively enforced by direct measures，there should be no need for a minimum landing size。

2）So long as mesh size sizes cannot be effectively enforced by direct mea－ sures，minimum landing sizes may be helpful for enforcement purposeso However， because discarding is also influenced by market prices，there are likely to be situations in which discarding will occur，even if there was no minimum landing size。

## 7．2 Relationship between Minimum Landing Size and Mesh Size

One procedure that has been widely used is to make the minimum landing size correspond to the $50 \%$ retention length of the mesh size in use。 This is one compromise between the need to reduce wastage on the one hand，and the need to accept some wastage for enforcement purposes on the other．

The Working Group considers that there is no optimal relationship between minimum landing size and mesh size。 To facilitate the selection of a possible enforcement policy，however，a plot is presented of possible mesh selection ogives for 90 mm meshes for the three species in Figure 40 Some examples of possible minimum landing sizes for a 90 mm mesh，related according to various criteria，are also given．

8．FISHING EFFORT（Tables 1．9－1．11）
Fishing effort data were available for trawlers and seiners of the English and Scottish fleets respectively in various areas．Estimates of total international fishing effort were obtained by raising the respective English and Scottish effort data to the total international catches of cod， haddock and whiting in the North Sea。 Statistically significant relation ships between these fishing effort effort series and the VPA estimates of fishing mortalities were only found，however，for North Sea cod，based on an index of English seiner effort。

9．REVIEW OF FISH RESOURCES
Details of the cod and whiting resources in the English Channel，and cod， haddock and whiting resources in Sub－areas VIII and IX are given in the Appendix．

## NOTES ON STOCK ASSESSMENT AND TAC CALCULATIONS

10．COD
10．1．North Sea（Sub－area IV）
10．1．1 VPA（Tables 2．1， 3.1 and 4．1）
The total international effort for cod，as calculated from English copou。eo data suggested that in 1977 the effort level had increased after the drop in 1976．For the period 1970－77 there has been no steady trend in estimated fishing effort and，therefore the average $F$ values estimated from VPA for the younger age groups during the years 1970－73 have been used as terminal

F values for 1977．For 5 year and older cod，a smoothed value was used as calculated from the $F$ values for age groups 5－8 during the same period．The terminal $F$ values used are consistent with the Inter－ national effort based on English seiners．

| 10．1．2 | Year＿class strength（Tables 5.2 and 5 |
| :---: | :---: |
|  | Year classes 1976 and 1977 were estimated from the predictive regression of VPA estimates on IYHS abundance indices（cfo Tables 5.2 and 5.3 ）as $330 \times 10^{6}$ and $175 \times 10^{6} 1$ year old fish respectively． For catch predictions，the fishing mortality on the 1976 year class in 1977 was adjusted to be consistent with the predicted strength of the 1976 year classo Yeariclass 1978，entering the fishery in 1979，was assumed to be of average size（ $206 \times 10^{6} 1$ year old fish）。 |
| 10.1 .3 | Catch predictions |
|  | The values of the different parameters used in the catch predictions are given in Table 6．l。 Numbers landed are the provisional figures available for 1977．F values correspond to the VPA input terminal $F$ values with the adjustment for age group $l$ as explained under lo．l．2．Weight at age data were the same as last yearo Input data were adjusted to ensure that the sum of products of the input numbers and the average weights coincided with the actual catch in 1977。 <br> To take account of the proposed change in mesh size to 90 mm in 1979 ， two selection factors have been applied to take account of the probable range of values．The corresponding $50 \%$ retention lengths were calculated and the corresponding $50 \%$ retention ages were estimated from the von Bertalanffy growth curve（ $L_{\infty}=115 \mathrm{~cm}$ ， $K=0.3, t_{0}=0.8$ years）。 The reduction in fishing effort on age group 1 was estimated from the proportion of the year that 1 group cod should be exploited with a 90 mm mesh size comparediwith the proportion of the year for which they should be exploited with a 75 mm mesh size。 In addition，account was taken of the increase expected in the average weight of 1 group landed，as a result of the introduction of the 90 mm mesh．The results of the catch predictions are given in Tables 5．1．A and 5oloB。 |
| 10.2 | West of Scotland（Division VIa） |
| 10．2．1 | VPA <br> There was no new information available for adjusting the terminal $F$ values compared with those in last year＇s VPA．Therefore the same value of 0.7 was used for all older age groupso For the younger age groups，input Fs were adjusted to be equal to be the averages for the period 1970－73。 |
| 10．2．2 | Year class strength <br> No direct estimates of the strengths of year classes 1976 and 1977 were available，and therefore average values，based on the numbers of 1 year old cod in 1966－75，had to be used in the catch predictions．The $F$ on the 1 year old fish in 1977 was adjusted so as to be consistent with the value used for the size of the 1976 year classo |
| 10.2 .3 | Catch predictions <br> Catch predictions were carried out for the alternative assumptions that effort remained at the level assumed for 1977，and that the effort in 1979 was $10 \%$ below the 1977 level。 |
|  | Because l group cod are exploited to only a very limited extent （ $F=0.075$ ）a change of mesh size to 90 mm in 1979 should not change the TAC significantly。 |

| 11． | HADDOCK |
| :--- | :--- |
| 11．1． | Sub－Area IV |
| 11．1．1． | VPA |
| 11．1．1．1． | Input data（age composition）（ |

Data for years 1959－74 were the same as those used in last year＇s analysis． Data for 1975 and 1976 were revised to take account of new information．For 1977，provisional age composition data were available from Denmark，England， Netherlands，Norway and Scotland；length composition data were provided by Belgium and France．Numbers at age were tabulated separately for the industrial（Rec．2）landings，consumption landings（Rec．4），and for discards， and were then summed after adjusting by sums of products（ $\Sigma$ number x mean weight）。

11．1．1．2．Input F．values（Table 3．2）
In the absence of significant correlations between various measures of international effort and $F$ values，smoothed average values for the period 1971－73 were used（ 1970 values were omitted since some are rather erratic）． $F$ values for age 0 and 1 were adjusted to correspond with year class strengths estimated by the IYHS．A value of $\mathbb{M}=0.2$ was assumed，throughout．

11．1．2．Year class strengths（Table 4．2）
Values for 1976 and 1977 year classes at age 1 （obtained from the IYHS－ see Section 10．1．2）were 460 and 694 million，respectively（Tables 5.2 － 5．3）．The 1978 year class at age 0 was assumed to be 611 million，calculated from VPA as the average of the period 1959－73，but excluding the exceptional 1962 and 1967 year classes．

11．1．3．Catch predictions（Tables 6．2，6．7，6．8）
The starting point was the number of fish at each age landed from the industrial and consumption fisheries，and for the discards．Separate mean weights per age group were used for each of these categories and a weighted mean was used for the combined categories．

The Group was requested to investigate the effect on the 1979 TAC of possible changes in mesh size and predictions were made assuming an increase to 90 mm in the Rec． 4 fisheries in 1979．In view of the range in selection factors reported in the literature，it was decided to use a high and a low selection factor in the predictions involving a mesh increase．

Two main options were considered for 1978；that fishing effort remains the same as in 1977 （Option A）or that fishing effort is such that the TAC agreed between EEC and Norway（109000 tons）is taken（Option B）．

For Option A，the predicted landings will exceed the TAC and the following possibilities（referred to as run number in Tables 6.7 and 6．8）were considered for 1979．

1．No mesh change．No change in fishing effort．
2．No mesh change．Effort reduced by $10 \%$ 。
3．Mesh in Rec． 4 fisheries increased to 90 mm 。
Low selection factor．No change in fishing effort．
4．As for（3）but with high selection factor．
5．As for（3）but fishing effort reduced by $10 \%$ ．
6．As for（4）but fishing effort reduced by $10 \%$ ．

For Option B, a reduction in effort of $20 \%$ will occur in 1978 and predictions for 1979 were made on the assumption that fishing effort remains at this reduced level. Three further possibilities for 1979 were considered:

1. No mesh change.
2. Mesh in Rec. 4 fisheries increased to 90 mm . Low selection factor.
3. As for (2) but with higher selection factor.

The simulation of the various eventualities for 1979 referred to above was carried out as follows.

Values of $F$-at-age for the Rec. 2 fishery and for the Rec. 4 fishery (landings and discards) in 1977 were estimated using the following relationships.

$$
\begin{aligned}
& \text { Recommendation } 4 F_{t}=\frac{\text { Recommendation } 4 C_{t} \cdot \text { Total } F_{t}}{\text { Total } C_{t}} \\
& \text { Recommendation } 2 F_{t}=\frac{\text { Recommendation } 2 C_{t} \cdot \text { Total } F_{t}}{\text { Total } C_{t}} \\
& \left(F_{t}=F \text {-at-age, } C_{t}=\text { catch in numbers at age }\right)
\end{aligned}
$$

Mean weight at age was calculated for the Rec. 4 catch (landings and discards) and these mean weights were converted to mean length using an approprite length-weight function $\left(L=(w / .009)^{1 / 3}\right.$ for haddock).

For each eventuality considered, the ratio percent retained by new mesh; percent retained by old mesh was calculated for each mean length at age. In the case of a proposed decrease in fishing effort, each of these ratios was multiplied by an appropriate value (e.g., for a proposed $10 \%$ reduction in effort the ratios were multiplied by 0.9). The values thus obtained estimate the proportional change in F-at-age in the Rec. 4 fishery and were used to estimate new $F$-at-age arrays for that fishery.

For each simulation referred to in these tables, values of $F$-at-age for the Rec. 2 fishery were changed appropriately in cases where a decrease in fishing effort was proposed.

Table 6.7 shows the estimated changes (expressed as percentages) in the Rec. 4 F-at-age for each eventuality considered under Option A, while Table 6.8 shows corresponding values under Option B. Also included in these tables are the results of each simulation run. The results for catches and landings are summarised in Table 5.1A.

```
11.2. Division VIa
11.2.1. VPA
11.2.1.1. Input data (age composition)(Table 2.5)
```

Revised data for 1976 and provisional data for 1977 were available. For 1977, age composition data were provided by England, Ireland and Scotland. The data base for years prior to 1976 was the same as that used for last year's assessment.
11.2.1.2. Input F values (Table 3.5)

There were no significant correlations between measures of international effort and VPA $F$ values, and average values for the period 1971-73 were therefore used. The $F$ value at age $l$ was adjusted to correspond to an estimatedrecruitment value (see following section).

11．2．2．Year class strengths（Table 4．5）
A significant correlation between VPA estimates of number at age 1 in the North Sea and in Division VIa was found（Figure 5）．Using this correlation， the number of fish of the 1977 year class at age 1 was estimated（from IYHS） to be 45 million．An average recruitment of 32 million at age 1 in 1979 was assumed，calculated as the VPA average for the years 1965－73，but excluding the exceptional 1967 year class．

11．2．3．Catch predictions（Tables 6．5，6．10）
These were basically similar to those previously described（see ll．l．3） except that there was no Option B，since there is no agreed TAC for 1978. It was assumed，therefore，that fishing effort in 1978 will be the same as in 1977.

12．WHITING
12．1 Sub－area IV
12．1．1 VPA
12．1．1．l Input data（age compositions）（Table 2．3）
Data for the years $1960-75$ were the same as those in last year＇s analysis． Data for the consumption and industrial fisheries and for discards in 1976 were updated。 For 1977，age composition data were available from belgium，Denmark，England，Netherlands，Norway and Scotlando France pro－ vided a 1977 length frequency which was converted to an age frequency using Scottish age－length data．Numbers at age for the consumption and industrial fisheries and for discards were determined。

12．1．1．2 Input $F$ values（Table 3．3）
No significant correlations were found between various measures of interm national effort and values of $F$ taken from trial VPA runs．For this reasons average values of F－at－age for the period 1970－73 were used as input values in 1977。 Values of $F$ for ages 0 and 1 were adjusted to prom duce numbers of fish in the sea in agreement with recruitment estimates obtained from the IYHS data（see below）。 A value of $M=0.2$ was assumed． for all ages and yearso

12．1．2 Year Class Strength
From the results of the IYHS（see Section 10.1 .2 and Tables 5.2 and 5．3） it was estimated that there were 1201 and $1207 \times 10^{6}$ whiting of age 1 in 1977 and 1978，respectively。
The 1978 and 1979 year classes at age 0 were assessed to be 1643 million fish，this value being the mean number of 0 group fish for the period 1959－73。

12．1．3 Catch Predictions（Tables 6.3 and 6．9）
These were basically the same as those described previously（see Section ll． 1.3 ），except that Option B predictions were not made．This was because the present assessment shows that fishing effort would need to be doubled in 1978，in order to take the EEC／Norway agreed TAC。 Such an increase in fishing effort was considered to be unrealistic，and consequently only Option $A$ was run．
Mean weights were converted to mean lengths using the relationship：

$$
\left(L=5^{\mathrm{w}} \mathrm{l} / 3\right)
$$

| 12.2 | Divisions VIa and VIb |
| :--- | :--- |
| 12.2 .1 | VPA |
| 12.2 .1 .1 | Input＿data（age compositions）（Table 2．6） |

Revised data for 1976 and provisional data for 1977 were available。 Age composition data were provided by Scotland and Ireland。 Dáta for years prior to 1976 were unchanged．

## 12．2．1．2 Input F values（Table 3．6）

No correlation was found between measures of total fishing effort and VPA $F$ values，and therefore average values for the period 1970－73 were usede $F$ values for age groups 0 and 1 were adjusted to correspond with recruitments estimated from IYHS（see following Section）。
$M$ was assumed to be 0.2 at all ageso
12．2．2 Year Class Strength（Section 10．1．2，and Tables 5．2 and 5．3）
A significant correlation was found between the VPA abundance at age 1 in the North Sea and in Division VIa（Figure 6）。 Estimates of the strength of the 1976 and 1977 year classes in Division VIa could therefore be made on the basis of estimates for Sub－area IV from IYHS．These gave values of 71 million at age 1 for both year classes．The 1978 year class was estimated at 102 million at age 0 ， this being the VPA average for the period 1960－73．

12．2．3 Catch Predictions（Tables 6.6 and 6．11）
These were basically the same as those previously described（see Section llol．3），escept that，because there is no agreed TAC for 1978， Option $B$ was not applicable。

## 13.

NOTES ON MESH ASSESSNENTS
The mesh assessments were made using the method of Gulland（1961）1）。 The assessments were made for cod，haddock and whiting in Division VIa，and for cod and whiting in Division VIId。 Tables 7．l to 7．5 show the input length distributions used for analysis，the current mesh sizes and the calculated weights at lengtho Tables 7.6 to 7010 show the values of $t^{0, *}$ ，fishing mortality，the $50 \%$ and $75 \%$ selection points for the current mesh sizes and also for the proposed 90 mm mesh．These are given for two options of selection factor for each fleet in each stock and area．The selection factors were chosen to represent low and high values taken from the literature。 Tables 7．ll to 7.15 show the gains and losses for each fleet for each stock／area． Table 7.16 gives their values and sources．
The fishing mortalities used in the analyses were as follows：for Division VIa cod（ 0.4 ），haddock（ 0.3 ）and whiting（ 1.0 ）。 These were based on VPA results for recent years．For Division VIId cod and whiting，a value of 0.7 was used，based on French catch curve information。

1）Gulland，JoA．1961．The estimation of the effect on catches of changes in gear selectivityo JoConsoint。Explor．Mer，26（2）：204－214。
＊） $\mathrm{H}^{\prime}$ is half the estimated time required to grow from the $50 \%$ release length of the current mesh size to the $50 \%$ release length of the new mesh。

The values of to were estimated from available length at age and weight at age data.
14.
15.

TIMING OF WORKING GROUP MEETINGS
The Group discussed the timing of Working Group meetings and concluded that there would be advantages if these meetings took place during the second half of the year. The advantages are:

1) It would allow extra time for processing data for the previous year. Data from the first part of the current year should also be avallable。
2) For cod, haddock and whiting, it should enable additional recruitment estimates from pelagic 0-group surveys, to become available for the assessments.
3) It should enable TACs to be estimated with greater precision.

## Cod in Division IIIa

Landings of German Democratic Republic in 1969-72 included in Sub-area IV. Landings of Sweden in 1967-74 included in Sub-area IV.
Landings of Federal Republic of Germany for 1968-70 include miscellaneous products.

## Haddock in Division IIIa

Landings of German Democratic Republic in 1969-72 included in Sub-area IV. Landings of Sweden in 1968-74 included in Sub-area IV.

Whiting in Division IIIa
Landings of Sweden in 1967-74 included in Sub-area IV.

## Cod in Sub-area IV

German Democratic Republic landings in 1969-72 included in Division IIIa. Sweden: landings 1967-74 include Division IIIa.
Germany, Fed.Rep. of landings in 1968-70 include miscellaneous products. For Netherlands: not included for 1967: 3369 tons and 1968: 1132 tons. For 1977 Faroe Islands human consumption only.

## Haddock in Sub-area IV

Landings for German Democratic Republic for 1969-72 include Division IIIa.
Landings for Sweden for 1968-74 include Division IIIa.
Netherlands: not included for 1967: 720 tons and for 1968: 306 tons caught mostly in Division IVb, rest in Division IVc.

Whiting in Sub-area IV
Landings for Sweden for 1967-74 include Division IIIa.
Netherlands: not included for 1967: 913 tons and for 1968: 267 tons.
For 1977 Faroe Islands human consumption only.
Cod in Sub-area VI
Landings for Germany, Fed.Rep. for 1968-70 include miscellaneous products.

Table l. 2 COD. Division IIIa and the Divisions of Sub-areas IV, VI and VII. Nominal catch by Divisions in metric tons 1967-77.

Faroe Islands figure for 1977
French figure for 1969
Norwegian figures for 1967-72 and $1977 \quad\{$ included in Division IVa
Swedish figures for 1967-74 and 1976-77
USSR figures for 1967-73 and 1977
Danish figures for 1967-73 include Division IVa
Netherlands: not included for 1967: 913 tons and for 1968: 257 tons caught mostly in Division IVb, rest in Division IVc.
Swedish figure for 1975 includes Divisions IVa,c.
Danish figure for 1977 included in Division IVa.

## Division IVc

French figure for 1969
Norwegian figures for 1967-69
Swedish figure for 1977
included in Division IVa.
USSR figures for 1967-73 and 1977)

Footnotes to Table 1.4 (ctd)
Division IVc (ctd)
Netherlands: not included for 1967: 913 tons and for 1968: 257 tons caught mostly in Division IVb, rest in Division IVc.
Swedish figure for 1975 included in Division IVb.
Danish figure for 1977 included in Division IVa.

Division VIIa
French figure for 1971 includes Division VIIf.

Division VIIf
French figure for 1971 included in Division VIIa.

| B4 | 159 | $75(85)$ | - |
| B5 | - | $70(77)$ | - |
| B6 | - | - | - |

Option A Assuming 1978 effort $=1977$ effort.
Option B Assuming 1978 effort is adjusted to just take up 1978 TAC.

1 No mesh change $F_{79}=F_{77}$
2 No mesh change $\mathrm{F}_{79}=0.9 \mathrm{~F}_{77}$
3 Mesh change to 90 mm in 1979, $\mathrm{F}_{79}=\mathrm{F}_{77}$, low selection factor.
4 Mesh change to 90 mm in 1979, $\mathrm{F}_{79}=\mathrm{F}_{77}$, high selection factor.
5 Mesh change to 90 mm in 1979, $\mathrm{F}_{79}=0.9 \mathrm{~F}_{77}$, low selection factor.
6 Mesh change to 90 mm in $1979, \mathrm{~F}_{79}=0.9 \mathrm{~F}_{77}$, high selection factor.

1) For haddock, Option $B, F_{79}=F_{78}=0.8 F_{77}$ for options given.

## APPENDIX

## REVIEW OF FISH RESOTJRCES

The Appendix deals with cod and whiting in the English Channel and cod，haddock and whiting in Sub－areas VIII and IX。

1．ENGLISH CHANNEL COD AND WHITING
1．1 Cod
l．l．l General biology，distribution and migrations
Although cod spawn at a low intensity in the eastern English Channel it seems likely that the cod caught in the Channel mainly originate from the Southern Bight spawning。 They first appear as 0－group during December at an average length of 22 cm （range 14 to 31 cm ）in localised areas such as the Varne Bank，Bassin de Baas and in certain parts of Rye Bay，for example．It＇is possible that they migrate actively into the area from the Southern Bight when the spawning there has been particularly successful or it may be that recruitment to the Channel is dependent upon the direction and amount of residual drift through the Straits of Dover．
Most l－group cod remainiin the eastern English Channel during their first summer although some move west into ICES Division VIIe and are caught off Plymouth in July，while others move north into the deeper parts of the Straits of Dover off Ramsgate．The accepted idea is of a northwards migration of southerly fish into the central North Sea in the summer（Bedford，1966；Lefranc，1969）．This is not so，however，for 1 year old Ghảnel cod．

## I．I＇．2 Exploitation and management

Exploitation proper begins to take place as early as April on the larger l－group fish and recruitment is effectively complete by July when all of them exceed 30 cm ．Exploitation in the eastern Channel continues during the autumn and there is evidence that＂Channel＂logroups are joined in December by much smaller l－group cod which have spent the summer north of $53^{\circ} \mathrm{N}$（ioe。，＂central North Sea＂fish）。
The classic view of southerly cod migrating northwards into the central North Sea in April is possibly fulfilled by those 2 year old Channel fish which lived as l－group fish in the central North Sea，but may not be ful－ filled by those which have grown up in the Channelo Tagging experiments in progress at the moment should provide confirmation of this（De Clerk， 1973）。
There is no evidence of migration of cod between the Irish Sea or Bristol Channel and the English Channel．
The growth rate of＂Channel＂cod is certainly higher than that of＂central North Sea＂cod during their first two years of lifeo The mean weight at age of cod caught in the Channel is probably between that of the ＂Channel＂cod and that of the＂central North Sea＂cod as previously defined．

Even though Channel cod grow more quickly than North Sea cod and do not mix randomly with them，it would be inappropriate to treat them as a completely separate stock for assessment purposes．

## 1．2 Whiting

There is a considerable United Kingdom fishery for whiting in both ICES Divisions VIId and VIIe．The fishing caught in Division VIIe are probably spawned in Division VIIe，but it is not certain where the Division VIId whiting originate。 Small 0－group whiting are found in inshore areas such as Rye Bay in the autumn．

In Division VIId the main fishery takes place east of a line between． Beachy Head and the Somme．Some of these fish are immigrants from the southern North Sea（Rout，1962）．Trawl surveys in 1976 have shown that whiting in depths shallower than 20 m rarely exceed 30 cm ．Larger fish are found principally in water deeper than 20 m 。

In Division VIIe the United Kingdom fishery takes place from Brixham and Plymouth in inshore areas where peak catch rates are obtained in July．The growth rate in Division VIIe is very much higher than that in the North Sea．Fish of a particular age in Division VIIe are approximately twice the weight of North Sea fish of the same age （Appendix Figure 1）。

As some very large whiting have been captured in the eastern Channel in recent years by research vessels，it seems likely that the growth rate of Division VIId whiting is also high．This should be resolved finally this year when recently collected data are analysed．

As with Channel cod，it is likely that the Division VIId whiting are closely associated with whiting in the North Sea and should ben． assessed with them．For management purposes，the Division VIIe popu－ lation can possibly be treated as a separate stock．

2．SUB－AREA VIII
Relatively small landings of cod，haddock and whiting are recorded from Sub－area VIII．The fish caught here all come from the northern part of the area and can be regarded as belonging to the southern part of stocks primarily located within EEC waters。

3．SUB－AREA IX
No landings of cod，haddock or whiting are recorded from Sub－area IX。
