International Council for the Exploration of the Sea

C.M.1979/H: 8<br>Pelagic Fish Committee

This Report has not yet been approved by the International Council for the Exploration of the Sea; it has therefore at present the status of an internal document and does not represent advice given on behalf of the Council. The proviso that it shall not be cited without the consent of the Council should be strictly observed.

[^0]1. Introduction and Participation
1.1. Terms of Reference

At its Statutory Meeting in Copenhagen 1978, the International Council for the Exploration of the Sea (ICES) decided that the Atlanto-Scandian Herring Working Group should meet at the ICES headquartes for three days during the week 21-26 May 1979 to assess the state of the Atlanto-Scandian herring (Chairman: Mr. J. Jakobsson). The Group should also evaluate all available evidence on the relation of the capelin at Jan Mayen with neighbouring stocks.

Subsequently it was decided that the Working Group should meet in Bergen 21-23 May.

### 1.2. Participants

2. Norwegian Spring Spawners
2.1. Catch statistics, age composition and growth curves

A summary of the herring fisheries (not divided by nations) for the period 1950 - 1978 is given in Table 2.1. In 1976 there was a fishing ban enforced and no recorded catches.

The age distribution of the spawning stock is given in Table 2.2. The age composition of the catches in 1977 and 1978 which were taken in the wintering area, is similar to that of the spawning stock. As described later in this report, the results from the tagging project indicate that the spawning stock is divided into a northern and a southern component. Table 2.2. gives the spawning stock age composition for both components for the period 1977 1979.

Figure 1 gives growth curves for the 1969, 1973, 1974 and 1975 yearclasses compared with earlier periods.

### 2.2. Echo registration of herring 1970-79

In the last Working Group report, an account of the recordings of herring for the period 1970-77 was given. It was pointed out that in the period 1973-76 the registrations of herring on the spawning grounds did not indicate any significant increase in the stock. However, in winter 1977, the amount of spawning herring increased significantly. The recordings in 1978 and 1979 did not indicate any further increase in the spawning stock. In the period 1977 - 1979 the destribution pattern has been unchanged with some schools and scattering layers off Mare and Trøndelag in late February and early March.

In 1977, registrations of spent herring were located on the Træna bank in late March. This also happened. in 1978, but the registrations were smaller.

Soviet investigations on herring distribution were carried out in the spring of 1976 and 1977 near the spawning grounds of the Norwegian spring spawners. In the second half of

1977 three Soviet research vessels surveyed large areas of the Norwegian Sea as well as in the Jan Mayen and the Jan Mayen - Spitsbergen region.

During these surveys no herring concentrations were located using acoustic methods but experimental fishing using both the driftnets and pelagic trawls yielded a few samples (Table 2.3.) in which the 1969 yearclass dominated.

In 1978 Soviet research vessels did not locate any herring concentrations, in the Norwegian Sea and the experimental fishing only yielded one single specimen of herring.

The registrations of immature herring indicate no major change in amount or geographical distribution in the period 1977 - 1979.
2.3. Larval surveys $1977-1979$

The previous Working Group report, gives the distribution charts of the herring larvae for the period 1968-1976.

In the period 1973 - 1979 a modified varsion of the Gulf III sampler has been used for the herring larvae sampling. The distribution of the herring larvae in 1977-1979 is shown in Figure 2. The Figure shows no major changes in the larvae production during this period.

### 2.4. Acoustic abundance of 0-group herring

An acoustic 0 -group survey has been carried out in coastal waters of western and northern Norway in October December 1974 - 1978.

An abundance estimate of 0 -group herring for the period

1974 - 1978 are given in Table 2.4. As described in the last Working Group report the 0 -group strength for the 1974 yearclass was probably underestimated, because all areas were not surveyed that year. More than $50 \%$ of the 1975 yearclass was recorded in the Trondheimsfjord. Biochemical investigations of the enzyme lactate dehydrogenase (LDH) of this yearclass indicate that the 0-group in the Trondheimsfjord in 1975 partly belonged to a local stock (Rabben 1978). In the autumn of 1978, more than $80 \%$ of the herring recorded in the Trondheimsfjord belonged to the 1975 yearclass: This herring had a reduced growth rate compared with herring of the 1975 yearclass from other areas.

In 1976 - 1978 - group herring have been recorded in the Barents Sea during the joint 0 -group cruises. This component is not included in the estimate given in Table 2.4..

### 2.5. Tagging experiments

The herring tagging project which was described in the previous Working Group has been continued. Herring have been internally tagged and released at various localities along the Norwegian coast, and catches from an experimental fishery have been analysed for recoveries, using a tag indicator retaining internally tagged fish. Most of the catches screened for tags are taken during winter, either in the overwintering area of the mature stock or at the spawning grounds, but some few samples have also been obtained during autumn. The tagging is done in April May.
2.6. Stock structure and migration

Figures 3-5 show localities of release and recapture
obtained from the winter catches in 1977 to 79.
These data provide evidence to separate the herring stock in two spawning-components, a southern component spawning on the southern coast of Møre, (south of $63^{\circ} \mathrm{N}$ ) and a northern one, spawning north of $63^{\circ} \mathrm{N}$. The two components differ also in $l_{1}$-distribution, the southern one having the larger first year growth (Table 2.5). This difference was especially large for the 1973 yearclass.

In the 1970-ies the herring have remained in the Norwegian coastal waters after spawning and have not migrated to the feeding area off Iceland as in previous years. During summer and autumn, mature herring have been observed feeding in the coastal waters between Møre and Lofoten. In late autumn the herring migrate into the fjords for overwintering where they are found in very dense concentrations from October to February. The fjords of Lofoten are the main overwintering area of the northern component, whereas the herring of the southern component seem to stay at More throughout the year. During February - March there is a spawning migration from the fjords to the spawning grounds off the coast.

### 2.7. Abundance estimates of the spawning stock

In the previous Working Group report the size of the spawning stock in 1977 was considered to be about 200000 tons. This was derived from the tagging data obtained from the experimental fishing during the winter 1977. The experimental fishing has been continued in order to sample the stock and obtain tag returns for assessment purposes. Table 2.6 shows the number of releases and recoveries by years and localities of release. The releases recaught north of $63^{\circ} \mathrm{N}$ are grouped as northern component, whereas releases recaught to the south of that latitude are
considered to belong to the southern one. Most of the catch is obtained during the spawning season but a minor proportion is fished during autumn in the overwintering areas.
2.7.1. Northern stock component

The table below summarizes the recoveries and corresponding catch of the northern component for the winters 1977, 1978 and 1979:

| Release <br> Year <br> m |  | 1977 | Recoveries |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1978 | 1979 | Sum |  |  |  |
| 1975 | 24959 | 12 | 14 | 8 | 34 |
| 1977 | 13456 |  | 10 | 17 | 27 |
| 1978 | 10380 |  |  | 13 | 13 |

The table includes the releases which are dominated by the age groups older than the 1974 yearclass, with the exception of Jøkelfjord and Altafjord in 1975 and Nordøyane in 1977. These batches are considered as unsuccessfull releases. The catches refer to the yearclasses 1973 and older herring exclusively.

The abundance of this stock component was calculated from these data:
$N_{1975}=\frac{0.7 \cdot 24959 \cdot 2354 \cdot 10^{3}}{34}=1210 \cdot 10^{6}$
$N_{1977}=\frac{0.7 \cdot 13456 \cdot 1415 \cdot 10^{3}}{27}=494 \cdot 10^{6}$
$N_{1578}=\frac{0.7 \cdot 10380 \cdot 710 \cdot 10^{3}}{13}=397 \cdot 10^{6}$

The stock abundance estimates refer to the time of release of the respective years (May) and include the 1973 yearclass and older herring. The mortality due to the tagging operation is set at $30 \%$ (Dragesund and Jakobsson 1963): The following spawning stock estimates in number by age are obtained by the use of the age composition given in Table 2.2. and the age/weight data given in Table 2.7. :

Year
Yearclass es亡imate $\left(N \times 10^{-6}\right)$

The stock size estimates for 1975 - 78 show an average annual total mortality, $Z=0.37$. Using this value of total mortality rate for 1978-79 the present state of the northern component of the stock is:

Year

$$
1979
$$

$$
\begin{array}{ccccccc}
\text { Yearclass estimate } & \left(N \times 10^{-6}\right) \\
1976 & 1975 & 1974 & 1973 & 1972 & 1969 & \Sigma
\end{array} \begin{gathered}
\text { Total weight } \\
\text { (Tonnes } \times 10^{-3} \text { ) } \\
13
\end{gathered} 17 \begin{array}{llrlrll}
136 & 207 & 10 & 54 & 437 & 150
\end{array}
$$

On this basis it is found that the size of the northern stock component has decreased by about $30 \%$ in number and 20 \% in weight during the last two years.

### 2.7.2.Southern_stock component

The recoveries in the winter catches of 1978 and 1979 from the 1977 releases at Kvalvik and the 1978 releases at Hamnøy are used to assess the state of the southern spawning stock component:

| Release |  | $\begin{aligned} & \text { Recoveries } \\ & 1978 \quad 1979 \end{aligned}$ |  | Sum |
| :---: | :---: | :---: | :---: | :---: |
| 1977 | 5380 | 7 | 10 | 17 |
| 1978 | 3794 |  | 7 | 7 |
| Catch ( | $\times 10^{-3}$ | 150 | 241 | 391 |

The releases, recoveries and catch refer to the age groups older than the 1975-yearclass. The abundance of this stock component was calculated from these data:

$$
\begin{aligned}
& N_{1977}=\frac{0.7 \cdot 5380 \cdot 391 \cdot 10^{3}}{17}=87 \cdot 10^{6} \\
& N_{1978}=\frac{0.7 \cdot 3794 \cdot 241 \cdot 10^{3}}{7}=91 \cdot 10^{6}
\end{aligned}
$$

The release at Julsundet in 1975 (Table 2.6.) has given 9 recoveries in a catch of $139 \cdot 10^{3}$ individuals refering to the 1973 yearclass and older herring. This correspond to a stock size in 1975 of about $50 \cdot 10^{6}$ (Dragesund et al. 1978).

These estimates show that the southern stock component is far the smaller one, only $10-15$. \% of the northern stock component. The age composition of the southern component in 1979 is given in Table 2.2.

The tagging data together with the age composition thus indicate a southern stock level in 1979 of 100 • $10^{6}$ individuals or about 20000 tons.
2.7.3. Based on tag returns the 1979 spawning stock of the Norwegian Spring Spawning herring was thus estimated as described above to be about 170000 tons.

### 2.9. The prognosis for 1978-1979

The following prognosis of the spawning stock in 1978 and 1979 was made by the previous Working Group:

|  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Year | 3 | 4 | 5 | N <br> Age <br> 6 | 7 | 8 | 9 | Spawning stock in <br> weight |
| 1977 | 173 | 413 | 23 | - | - | 130 | - | 200 |
| 1978 | 934 | 295 | 352 | 20 | - | - | 110 | 432 |
| 1979 | 1380 | 1594 | 251 | 299 | 16 | - | 94 | 895 |

The development of the spawning stook has shown that this prognosis was far to optimistic.

The prognosis was made on the following basis.
A. The spawning stock in number by age in 1977.
B. Acoustic estimates of the 1975 and 1976 yearclasses as 0-group fish (Table 2.4.).
C. For the years 1977-1979 $M=0.16$ (natural mortality used by previous Working Groups) and $F=0$ were used for all yearclasses.
D. Recruitment to the spawning stock was set as $50 \%$ for the 3 -year old herring and $100 \%$ for the older.

Comments:
A. There is a slight overestimate of the 1973yearclass in the 1977 estimate of the spawning stock. (approximately $10 \%$ ). This is of minor importance.
B. As mentioned previously over 50 \% of the 1975 yearclass was recorded in the Trondheimsfjord. Later investigations show that this component of the 1975 belong to a local stock, and will thus not recruit to the spawning stock of the Norwegian spring spawners.

A certain fraction of the 0 -group estimate in other areas and years may also originate from local stocks.
C. The natural mortality estimate of 0.16 refers to the adult stock during the 1960-ies. The total annual mortality rate in the 1970ies obtained from the tagging experiments indicate a higher mortality due to other causes than officially reported landings. It is also possible that the mortality rate of juveniles are higher than in the adult stock. The effects of these factors will lead to an overestimate in the prognosis of the spawning stock.

In addition, the bycatch of juvenile herring in the sprat fishery may be considerable. This was not considered when the prognosis was made, and will have the same effect on the prognosis.
D. In the prognosis it was assumed that only $50 \%$ of the 1974 yearclass had matured in 1977. It was therefore expected that this yearclass would recruit to the spawning stock with a considerable amount in 1978. According to the age composition in 1978, the 1974 yearclass nearly fully recruited in 1977. The early recruitment was probably due
to a rapid growth (Figure 1 and Table 2-5). The 1975 (and 1976) yearclass have had a reduced growth rate compared with yearclass 1973 and 1974. The growth rate of these yearclasses is compared with the 1969 yearclass. And this yearclass did not recruit to the spawning stock before the age of 4 years. The age distribution of the spawning stock in 1978 and 1979 shows that the 1975 yearclass did neither recruit as 3 or as 4 ringers in any significant numbers.

The effect of all these factors combined has resulted in a decrease of the spawning stock instead of the expected increase of about $100 \%$ annually.

The relation between the 0 -group estimates in the fjords and the subsequent recruitment to the spawning stock is as yet uncertain. A longer time series is obviously needed before these data can be used for stock prognoses.
2.10. Management Advice

As requested by ACFM the Working Group considered the optimal range of spawning size for the Norwegian spring spawning herring. It was noted that this had in fact been estimated by Dragesund, Hamre and Ulltang (1978). They found that a recruitment was drastically reduced at spawning stock size below 2.5 million tons. The

Working Group agreed that it should be the long term aim to rebuild the stock to at least this order of abundance. It was however recognized that it may be unrealistic to use criteria based on historic data, especially because the stock at present has a coastal distribution while prior to the seventies it had an oceanic distribution during the feeding and overwintering periods.

The Working Group considered the requirements in terms of spawning stock size and trends in recruitment which must be met before a directed fishery could be recommended. It was agreed that in this case a substantial increase in the spawning stock must be registered before a directed fishery can be recommended and that such a fishery should then be only a fraction of that increase.

As described in the section of the Abundance Estimates of the spawning stock, there has not been observed any increase in the spawning stock since 1977. On the contrary the data indicate that the stock may even have declined to only 170000 tons. In addition the recruitment from the 1977 and 1978 yearclasses is expected to be low. In the light of thisserious state of the stock the Working Group can only recommend that there should be no directed herring fishery in 1979 and 1980. It is further recommended that bycatches (e.g. in the sprat fishery) should also be limited as far as possible.

## 3. Faroese spring spawning herring

At the Faroe island three different groups of herring have been identified, two spring spawning components and one summer spawning. The summer spawners occur at irregular intervals and are only found in the fjords.

The larger spring spawning component spawned on the banks east of the islands in March - April, the other in the fjords in April - May. Mainly based on the age composition Joensen (1966) concluded that there were two different stocks. The bank spawners arrived to the spawning grounds in late February from the overwintering areas in the Norwegian Sea, and were formerly recognized as part of the Norwegian spring spawning stock spawning at the Faroes (Jakobsson 1970 ). A fishery on this component took place in the late sixties and was about 16000 t. in 1967. Since 1968 practically no bank spawning herring have been found on the Faroe plateau.

In 1978 maturing herring was reported from the spawning area on the banks in March as bycatch in the trawl fishery for cQd and haddock. A small sample was dominated by the 1968 yearclass. During an echo survey in February 1979 one school of maturing herring was recorded. A sample from this also proved to be dominated by the 1968 yearclass.

$$
\text { Age distribution of Faroese bank spawners in } 1979
$$

| Age | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| No. | 1 |  | 12 |  | 3 |  | 1 | 8 | 66 |  |  | 2 |

On a larval survey in 1978 subsequent to the spawning time no herring larvae were found. In the Faroese 0-group surveys in 1978 however a considerable increase in 0-group herring was recorded compared to 1977.

> Number of 0-group herring caught in the Faroese O-group surveys in 1977 and 1978

| Total catch | 1977 | 1978 |
| :--- | :---: | ---: |
| in number | 7 | 262 |
| No. of stations | 93 | 94 |
| Negative stations | 90 | 79 |

During 1978 herring was occasionally reported as bycatch in the trawlfishery indicating that the herring stayed on the plateau throughout the year.

The results of the echosurvey in 1979 during which on ly one school of herring was located indicates that this stock component is at a very low level with practically no recruitment since 1968.

The Working Group recommends that directed fishery for the bank spawning herring at the Faroes should be prohibited.

## 4. Icelandic Spring and Summer Spawners

Traditionally, two herring stocks spawn at Iceland i.e. Icelandic Spring and Summer Spawners. Both stocks collapsed during the sixties (Coop.Res.Rep. 17 and 30 and Jakobsson 1978).

On the 1 February 1972 a ban on herring fishing with all gear other than drift nets was introduced. This ban was in force until 15 September 1975. Since then the fishery has been limited by catch quotas, seasonal closures and minimum landing size ( 27 cm ). No recovery of the Spring. spawners has so far been observed and the fishery since 1975 has been based entirely on summer spawners.

### 4.1. The Fishery

The landings of summer spawning herring for 1969-1978 are given in Table 4.1.During the years 1969-1971 these fluctuated between 19500-11500 tons. These catches were at a much lower level than the ones taken in the early sixties when e.g. in 1963 a peak catch of 130300 tons was taken. During 1972-1974 the catches remained at a very low level (200-1200 tons) due to the fishing ban with all gear other than driftnets. The old Icelandic driftnet fishery terminated in 1959 so at that time there was no commercial fleetequipped for this fishery. Therefore there was no need for a ban on that fishery in the early 70-ies. Since 1975 there has been a steady increase in the catches. It should be noted that the catches prior to 1972 (Table 4.1) were all taken by purse seine but in 1972-1974 only driftnets were used while in 1975-1978 the catches were taken by both gear as shown in the text table below.

Landings and TAC's in 1000 tons of Icelandic summer spawners 1975-1978 by gear are given below

Purse seine Driftnets

### 4.2. Stock abundance and mortality rates

The assessment of the stock and the exploitation is based on acoustic stock abundance estimates and catches by age using a VPA.
4.2.1. The catch in number and mean weights

The catch in number of the Icelandic summer spawners are given in Table 4.2.During 1975-1977 the catches were predominated by the 1971 yearclass. In 1978 this yearclass was still very important in the catch although the 1974 yearclass was caught in higher numbers. The weight at age in grams is given for each year in Table 4.3. and used for calculating biomass. It should be noted that during the last few years there is a general declining trend in mean weights.

Thus the mean weights of 3 ringers was:

$$
\begin{array}{lllll}
1974 & 1975 & 1976 & 1977 & 1978
\end{array}
$$

Weight in g $262 \quad 241243217198$

This trend in declining mean weights may indicate a density dependent growth.
4.2.2. The Fishing mortality in 1978

As in previous years an echo abundance survey was carried out on the wintering grounds at south east Iceland in 1978. The integrator values per nautical mile and the area of the wintering concentration is shown in Fig. 6 . Using the estimate given by Jakobsson (1978) the echo abundance values obtained in this survey correspond to about 180000 tons of herring. The mean weights and the age distribution obtained from sampling the wintering
concentration was then used to calculate the abundance of each age group. The fishing mortality for 1978 was then calculated from these survey results and the catch data from the previous fishing season using the formula with $M=0.1$.

$$
\frac{N_{\text {Dec }} 1978}{C_{1978}}=\frac{e^{-Z}}{\left(1-e^{-Z}\right) \frac{F}{Z}}
$$

The results are given in the text table below

| Rings | $\begin{gathered} \text { Age } \\ \text { distrib. } \end{gathered}$ | Mean w by age | Echo stock in millions Dec. 1978 | $\begin{aligned} & \text { Catch in no } \\ & 1978 \\ & \text { in millions } \end{aligned}$ | $\mathrm{F}_{78}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 17 | 63 | 185 | 2.6 | 0.01 |
| 2 | 34 | 102 | 373 | 22.3 | 0.05 |
| 3 | 21 | 196 | 233 | 50.5 | 0.19 |
| 4 | 5 | 248 | 52 | 13.7 | 0.22 |
| 5 | 2 | 292 | 23 | 8.6 | 0.30 |
| 6 | 11 | 302 | 119 | 39.1 | 0.27 |
| 7 | 3 | 327 | 31 | 7.2 | 0.17 |
| 8 | 3 | 350 | 32 | 6.3 | 0.16 |
| $8+$ | - | 350 | 20 | 2.8 | 0.15 |

4.2.3. The Results of the VPA

A VPA was run with the input $F s$ obtained from the catch in number data in 1978 and the results of the Echo abundance survey, as described above using $M=0.1$. The results are given in Tables 4.4 and 4.5 .

During the most recent years 1975-1978 the adult. $F$ has increased from 0.08 to 0.21 . The adult stock biomass increased sharply in 1975 and has until 1977 been about 160000 tons. It should however be stressed that these estimates are all highly dependant on the results of the echo abundance survey.

As shown in Table 5 the 1971 yearclass is now estimated to have been about $520 \times 10^{6}$ herring as 1 ringers. The 1972 and the 1973 yearclasses were both weak (93 and 145 millions) while the 1974 and the 1975 yearclasses are estimated to about 400 millions as 1 ringers.

### 4.3. The state of the stock and advice of TAC

Based on the echo abundance estimate from December 1978 the adult stock biomass will be about 200000 tons in 1979. This level of stock abundance is well within the range of stock-biomass during the 1954-1963 period of high and steady recruitment (Jakobsson 1978).

A TAC for 1979 has been set at 35000 tons. This will generate an $F$ on the adult agegroups in 1979 which is close to the' $F_{0.1}$ which for this stock for the present fishing pattern is about $F=0.2$ (Jakobsson 1973).

The Working Group recommends that for 1980 the TAC should be calculated on the bases of the results of 1979 echo abundance survey and using an $F$ close to $F_{0.1}$.

## 5. The capelin at Jan Mayen

The Working Group noted that the relation of the capelin at Jan Mayen with neighbouring stocks had been considered by scientists from Faroes, Iceland and Norway during a meeting which was held in Reykjavik 27-29 March 1979. The Working Group agreed that the subject of the Jan Mayen capelin was fully dealt with in the report from the Reykjavik meeting. This capelin report is therefore appended to the Working Group report.

## APPENDIX

Report of the capelin meeting held in Reykjavik 27-29 March 1979.

1. Introduction

While scouting for blue whiting a Norwegian purse seiner located dense concentrations of capelin 15-20 n.m. SW of Jan Mayen in the middle of August 1978. The first catch of about 1300 tons was taken on the 19 August. During the following weeks the fishery moved northwards and mainly took place $N$ and NW of Jan Mayen. The Norwegian catches were taken in late August, September and early October. The Faroese and the Icelandic catches were taken in September only. The total international catches are given by countries in the text table below.

Catches in metric tons in the Jan Mayen area August-October 1978.

| Faroe | - | 3353 | - | 3353 |
| :--- | :---: | ---: | ---: | ---: |
| Iceland | - | 59937 | - | 59937 |
| Norway | 19776 | 133160 | 2306 | 154143 |

As a result of this new development in the Jan Mayen area Iceland invited scientists from Faroe and Norway to a meeting in Reykjavik to discuss (i) the identity of the Jan Mayen Capelin
(ii) the present state of the capelin stock
(iii) the $T A C$ of capelin for the coming season.

This meeting took place during 27-29 March 1979 in Reykjavik and the participants were:

Are Dommasnes, Havforskningsinstituttet, Bergen Johannes Hamre,
Jakob Jakobsson, Hafrannsóknastofnun, Reykjavík
Hjalti í Jakupsstovu, Fiskirannsóknarstovan, Thorshavn
Sveinn Sveinbjörnsson, Aafrannsóknastofnun, Reykjvik
Gunnar Sætersdal, Havforskningsinstuttet, Bergen
Hjálmar Vilhjálmsson, Hafrannsóknastofnun, Reykjavik.
2. The identity of the Jan Mayen Capelin.
2.1. Surveys.

The results from earlier surveys (in 1960 and onwards) were reviewed in order to study the historical occurrence of capelin in the Jan Mayen area.

During the sixties the area was surveyed regularly in spring (May-June) without positive results. In mid or late summer on the other hand the Jan Mayen area was reasonably well covered only in 1966 and 1967. In the former year dense consentrations were located north of Iceland (68 $\left.{ }^{\circ} \mathrm{N} 19^{\circ} \mathrm{W}\right)$ while in the latter year (July-August) they were located west of Jan Mayen $\left(71^{\circ} \mathrm{N} 12^{\circ} \mathrm{W}\right)$.

In the $1970^{\circ}$ s a few scouting surveys were carried out to locate capelin in the Jan Mayen area without positive results until August 1978. The coverage of the area was however poor and therefore it is not possible to draw any conclusions on the regularity of the occurrence of capelin in the Jan Mayen area.

During July-August 1978 the Icelandic summer fishery took place off $N W$ and $N$-Iceland. In September the fishery moved to Jan Mayen while in October it moved back to the area off NW Iceland. The movements of the main stock of capelin were reflected in the changes of the fishery. They are also in conformity with survey results in the same period.

Thus in September, while the fishing took place at Jan Mayen, an intensive search for capelin concentrations was carried out $N W$ and $N$ of Iceland on the Bjarni Sæmundsson with negative results. Similarly in October when the fishing had shifted to $N W$-Iceland the area $N W$ and $W$ of Jan Mayen was surveyed with a Norwegian scouting vessel also with negative results.
2.2. Tagging.

In July and early August 197811750 capelin were tagged with internal seel tags off the western $N$-coast of Iceland and the $N W$-peninsula. Four of these tags subsequently turned up in Norway from catches taken in the Jan Mayen area.

During the period 21-25 September 1978 further 5114 capelin were tagged by the same method to the $W$, of Jan Mayen. From this experment tags were recovered in October-December from catches taken $N$ and $N W$ off the $N W$-peninsula of Iceland. (Fig. 1).

In 197914 t゙ags from the Jan Mayen tagging experiment have been recovered so far. All these tags are from that component of the 1979 spawning stock which was fished off NE-, E- and SEIceland in the period January-March 1979. (Fig 1).

Tag returns, therefore, clearly indicate a migration from the deep water area off $N$-Iceland to Jan Mayen in August as well as a return of this capelin to spawn at the Icelandic coast in the wintertime.
2.3. Age distribution.

The age distribution from the Jan Mayen fishery 1978 as well as that from Icelandic summer, autumn and winter (spawning) fishery is given in Table 1 and Fig. 2. These age distributions are very similar and indicate that the Jan May fishery as well as the fishery at Iceland are based on the same capelin stock component which comes to spawn at the coast of Iceland during the next winter.

### 2.4. Hydrographic Conditions in 1978.

A survey of the waters off $W-N^{-}$, , and E-Iceland in spring 1978 indicated more or less normal hydrographic conditions compared to recentyears. The East Icelandic Current was pronounced and salinity off $N$-Iceland was relatively low.

As the summer advanced, however, a pronounced warming up of. the upper layers was observed resulting in indistinct border areas between the various warm and cold water masses. The extention of drift ice was consequently much reduced and in autumn the E-Greenland coast was practically free of drift ice north to the 72 parallel.

The above changes in the environment may well explain the extensive migrations of the capelin to northerly regions that took place in 1978.
2.5. Conclusions.

The survey results, the age distribution data and especially the tag returns in 1978 and 1979 clearly show that the maturing

Icelandic capelin migrated from the $N$-Iceland area to Jan Mayen in August. During late September and October the reverse migration took place to the area off $N W$ Iceland whence the spawning migration started at the beginning of 1979 as illustrated in Fig. 1.

Thus there exists convincing evidence that the capelin fishery which took place in the Jan Mayen area in AugustSeptember 1978 was based on the stock which has its spawning grounds at the Icelandic coast. This main conclusion does not precilude the Dossible existence at Jan Mayen of a local stock (or stocks) which spawns in the area. Such local stocks are known from many Artic coasts, e.g. the Greenland fjords, but these stocks are small and generally not of commercial interest.
3. Abundance estimates state of the stock and recommendations for TAC.

Acoustic abundance estimates of the Icelandic capelin stocks were obtained for the first time in October 1978 when the capelin concentrations were located $N W$ of Iceland. Based on preliminary target strength estimates the results indicate that the prespawning stock was in the order of 1.3 million tons. Subsequently during the spawning migration in 1979 three further echo abundance surveys were carried out. Based on the same preliminary target strength estimates the results are consistent with the October findings.

Comparable measures of 0 -group abundance are available from August surveys since 1972. In the text table below the $0-$ group abundance index as well as the corresponding catches of the parent stock (the winter fishery and the summer and autumn fishery of the previous year) is given.

| The 0-group indices and catches from the parent stock. |  |  |
| :--- | :---: | :---: |
|  | Catch |  |
| 1972 | 277 | 0 -group index |
| 1973 | 441 | 89 |
| 1974 | 462 | 116 |
| 1975 | 458 | 134 |
| $1975-76$ | 342 | 89 |
| $1976-77$ | 659 | 60 |
| $1977-78$ | 770 | 43 |
| $1978-79$ | 1.191 | 31 |
|  |  | $?$ |

During the period 1972-1975 the 0-group index indicates a high level of recruitment but in later years there is definite downward trend in the recruitment to a level in 1977 and 1978 which is about $1 / 3$ of that observed in 1972-1975. At the same time there is a sharp increase in the fishing from about 400.000 tons in 1972-1976 to about 1.200.000 in 1978-1979.

Decrease in recruitment during a period of sharp increase of the catches is considered a danger sign as this could mean that the recruitment has been seriously reduced by the fishery since 1977. The stock may therefore have been over exploited and the need for caution in management must be stressed.

Judging by the 0 -group index the recruitment to the fishable stock in 1979-1980 will be considerably reduced as compared with former years. The group therefore recommends that a orecantionary TAC of 600.000 tons be set for the period summer 1979 to spring 1980 for the Icelandic economic zone, the EastGreenland waters and in the Jan Mayen area.

When the results of the summer and autumn surveys (acoustic abundance and 0-group) become available this precautionary TAC will be reconsidered and if necessary revised.
4. Management.

Until 1978 regulatory measures have mainly been precautionary in nature. Since 1973 there has been a closed season from 14 May lasting for $2-3$ months. In addition, the juvenile overwintering areas have been closed for all fishing. In 1975 a minimum landing size of: 12 cm was introduced. In 1978 the autumn season was stopped on 14 December and the winter season 1979 did not start until 10 January. The winter season 1979 was closed at south Iceland on 5 th March and at west Iceland on the 18 th March.
5. Research cooperation in 1979.

In order to update the information on the state of the stock and obtain a better assessment of the size of the fishable component of the stock for the $1979-1980$ season the following plans for a
joint survey were agreed: Two ships, G:O. Sars and Bjarni Sæmundsson, will conduct an acoustic survey of the expected area of distribution of the capelin between $66^{\circ}$ and $72^{\circ} \mathrm{N}$ for a period of about two weeks starting from Iceland in late July to mid August. Expert personel will be exchanged for the duration of the survey and special calibration runs will be arranged between the two vessels. A detailed plan will be worked out by correspondence. The observationswill be processed on a current basis on board and it is hoped that a stock estimate will be available at the end of the cruise.

If the distribution and behaviour of the capelin during August is found to be unsuitable for acoustic abundance estimation, consideration will be given to a renewed joint effort to assess the stock abundance in another two ship survey in September when the Norwegian research vessel "Michael Sars" is scheduled for a cruise in the Jan Mayen area.

The age distribution of capelin in the Iceland-Jan Mayen area in summer and
autumn 1978 and in september 1979.
