Executive Summary

The ICES herring assessment working group (HAWG) met for 10 days in March 2005 to assess the state of 7 herring stocks and 3 sprat stocks. HAWG was able to carry out age-based assessments on 3 of the herring stocks: North Sea autumn spawners, western Baltic spring spawners and autumn spawning herring to the west of Scotland. Exploratory assessments were carried out on herring in the Irish Sea and to the north / north west of Ireland. Problems were encountered in assessing herring in the Celtic Sea but broad trends in the population could still be determined. No assessment of Clyde herring was carried out due to lack of survey data and the poor quality of catch data. The dynamics of sprat in the North Sea and ICES area IIIa were examined and broadly described, but no investigation of sprat in the English Channel could be carried out as no suitable catch and survey data were available. The assessments of the autumn spawners in the North Sea, herring to west of Scotland, the western Baltic spring spawners were consistent with those presented last year, resulting in little changes in the perception of the stocks. Although another successive weaker than average year class will recruit to the North Sea autumn spawners in 2005, thus reducing the potential productivity of that stock in the short term.

i

The working group also commented on the quality and availability of data, the problems with estimating the amounts of discarded fish, the relevance of ecosystem changes to the stocks considered by the group and recent meetings and reports of relevance to HAWG. It also made nine recommendations about issues that affect the group.

The Stock Annexes of the Quality Control Handbook have been drafted and are attached to the HAWG report. In many cases these are incomplete as there is a large amount of information needed for each and they take a considerable amount of time to compile. For stocks without an accepted assessment, general elements (stock definitions, fisheries and ecosystem aspects) are presented.

2ACFM03

The Herring Assessment Working Group for the Area South of 62°N [HAWG] (Chair: Mark Dickey-Collas) will meet at *ICES Headquarters* from 8-17 March 2005 to:

1

- a. assess the status of and provide management options (by fleet where possible) for 2006 for:
 - i. the North Sea autumn-spawning herring stock in Division IIIa, Sub-area IV, and Division VIId (separately, if possible, for Divisions IVc and VIId);
 - ii. the herring stocks in Division VIa and Sub-area VII;
 - iii. the stock of spring-spawning herring in Division IIIa and Sub-divisions 22–24 (Western Baltic);
- b. forecasts for North Sea autumn-spawning herring should be provided by fleet and according to the management plan agreed between the EU and Norway;
- c. catch options for Div. IIIa shall be given by fleets taking into account that North Sea herring and Western Baltic herring are taken together in this Division;
- d. assess the status of the sprat stocks in Subarea IV and Divisions IIIa and VIId,e;
- e. for the stocks mentioned in a) and d) perform the tasks described in C.Res. 2ACFM01.

HAWG will report by 18 March 2005 for the attention of ACFM.

There were no additional requests from ACFM.

1.3 Working Group's response to ad hoc requests

1.3.1 Request by SGBYSAL

HAWG— as all other ICES groups dealing with pelagic stocks in the Northeast-Atlantic — was asked to contribute to the Study Group on Bycatches of Salmon in Pelagic Fisheries (SGBY-SAL). SGBYSAL requested weekly catch information for fisheries potentially bycatching

salmon postsmolts and adults, for a specified period of the year, and as far back as possible. As stated earlier, HAWG is not in the position to deliver data directly from its data holdings, because it is only collated quarterly and never as weekly catch data. However, HAWG encouraged national laboratories collecting data on herring fisheries in its area to contribute data to SGBYSAL at the required level of disaggregation.

Among nations participating in the herring fishery south of 62°N, Norway, Denmark, Ireland, England/UK, Germany, the Faroese and Scotland/UK delivered data to the SGBYSAL meeting in February 2005, for periods varying from 2-15 years, but almost all covered 2000-2003. Only The Netherlands and France felt unable to prepare the data as requested. However, data appeared to be sufficient to study the possible overlap in time and space of salmon and pelagic fisheries in the North East Atlantic. Also, the group started to identify fisheries that represent the greatest risk to the salmon. In general, fisheries catching fish at or close to the surface appeared to be most risky for salmon, but since purse seines are covering only limited areas, they represent lesser risk than trawls which cover large areas. Hence, trawl fisheries for mackerel performed close to the surface pose the greatest danger for intercepting salmon. Herring trawling represents lesser risk for the youngest stages of salmon, but there are anecdotal reports (ICES, WGNAS, 2003) of occasional large number of salmon being taken in herring catches. An overlap between herring fisheries and known postsmolt distribution was identified in the area west of Scotland and in the Faroes -Shetland area, predominantly in week 23-24 and possibly before, but there is little data on potsmolt prior to week 23, and the fisheries are rather small at the time of the postsmolt passage. SGBYSAL recommends that data on postsmolt bycatch should be collected from onboard observers, and that the nations which haven't delivered data to SGBYSAL do so as soon as possible.

1.4 Reviews of groups or work important for the WG

1.4.1 The Planning Group for Herring Surveys [PGHERS]

PGHERS met in Bergen, Norway, from 24–28 January 2005 (Chair: B. Couperus, Netherlands) to:

- a. combine the 2004 survey data to provide indices of abundance for the population within the area;
- b. coordinate the timing, area and effort allocation, and methodologies for acoustic and larvae surveys for herring and sprat in the North Sea, Divisions VIa and IIIa and Western Baltic in 2005;
- c. review and update the PGHERS manual for acoustic surveys to address standardization of all sampling tools and survey gears;
- d. review the results of an exchange exercise on herring maturity staging, and comment on the implications of the conclusions of the sprat age reading exchange and Workshop for the Acoustic Surveys;
- e. evaluate the results of the investigations of survey overlaps between vessels in the North Sea acoustic survey;
- f. to conduct an Echogram Scrutiny Workshop aiming at further harmonisation of scrutiny procedures.

Review of larvae surveys in 2004/2005. At the time of writing the report two of the seven surveys in the North Sea remained to be carried out in January 2005. There were subsequently completed successfully and the results were made ready for this Herring Assessment Working Group (HAWG) meeting. These are reported in Section 2.3.2

Co-ordination of larvae surveys for 2005/2006. In the 2005/2006 period, the Netherlands and Germany will undertake 6 larvae surveys in the North Sea from 1 September 2004 to 31 January 2005. The Baltic Sea Fisheries Institute will continue with the larvae survey in the Greifswalder Bodden area in 2005.

North Sea acoustic surveys in 2005. Six acoustic surveys were carried out during late June and July 2004 covering the North Sea and west of Scotland. The provisional total combined estimate of North Sea spawning stock biomass (SSB) is 2.6 million t, a decrease from 3.1 million t in 2003. The survey again shows two well-above average year classes of herring (1998 and 2000). Growth of the 2000 year class seems still to be slower than average. The west of Scotland SSB estimate is 400,000 t (739,000 t in 2003). The surveys were reported individually in Annex 2 of the PGHERS report. The survey results are presented in section 2.3.1.

Western Baltic acoustic survey in 2004. A joint German-Danish acoustic survey was carried out with RV "Solea" from 29 September to 18 October in the Western Baltic. The estimate of Western Baltic spring spawning herring SSB is 192,100 t, an increase since 2003 (106,000 t). A full survey report was given in Annex 3 of the PGHERS report. The results of the survey are given in section 3.3.

Survey overlap between FRV "Scotia", FRV "G.O. Sars". During the 2004 surveys two areas were selected for overlap, involving FRV Scotia and FV Enterprise in one area and "Johan Hjort", "Walther Herwig III" and "Dana" in another area. No significant differences have been found. However, this is not just confirmation of similar performance, but also illustrates the difficulty of obtaining sufficient precision to establish significant differences.

Manuals for acoustic and herring larvae surveys. The manual for herring acoustic surveys in ICES Divisions III, IV, and VIA has been reviewed and updated according to TOR (c) The new version 3.2 is provided in Annex 4 of the PGHERS report. There was no need for an update of the IHLS manual.

Exchange exercise on herring maturity staging. A selection of digital images was prepared from a collection of Dutch, Irish, Norwegian and Scottish pictures, and distributed digitally to all the participating laboratories. This is further discussed in section 1.4.11

Status and future of the HERSUR database. The upload of data at least for one year has been done with the exception of Norwegian data and Dutch ALKs.

It is currently intended that a higher-level database holding national aggregated data with survey results is to be set up by DIFRES, this will be based on the consistency-checked data available from previous North Sea acoustic surveys, kept at Aberdeen. This database would then used to further develop an automated system for delivering the outputs needed for the combined survey report and HAWG removing the need for the current MS Excel data system.

Sprat. Data on sprat were only available from RV "Walther Herwig III", RV "Tridens" and RV "Dana". Other vessels caught no sprat. The total sprat biomass estimated was 360,000 t in the North Sea (up from 270,000 t in 2003) and 15,000 t in the Kattegat (up from 13,000 t in 2003).

Co-ordination of acoustic surveys in 2005. Six acoustic surveys will be carried out in the North Sea and west of Scotland in 2005 between 28 June and 27 July. Small changes to the design are proposed and "Tridens" and "Walther Herwig" will cover the area between 52° and 57° together with interlaced transects. A survey of the western Baltic and southern part of Kattegat, will be carried out by a German research vessel from 4 to 24 October.

Scrutiny workshop. A scrutiny workshop was held on 25 and 26 January. Five teams scrutinized six data sets (3 BI500 sets and 3 echoview sets) of which one BI500 set was later excluded, because time and position data were lost in the post logging process. Preliminary results show reasonable agreement between the teams. The data will be analysed and presented in a paper before the next PGHERS meeting.

1.4.2 The Annual Meeting of Assessment Working Group Chairs [AMAWGC]

The working group read the report from AMAWGC 2005 and noted that many of the chapters were pertinent to HAWG. Specifically the request to give advice relevant to the new ACFM sheets, the comments and advice on management strategies, the information and comments provided by WGRED (Working Group for Regional Ecosystem Description) and the approach advised by AMAWGC on how to handle misreported and unallocated catches.

HAWG agrees with the need for management strategies to be consistent with the knowledge base available for each stock, and considered the idea of thinking "out-side the box" very relevant to many of the stock assessed by the group (see 1.4.10 on SGMAS). Comments on the WGRED are given in section 1.8.

1.4.3 Study Group on Regional Scale Ecology of Small Pelagics [SGRESP]

HAWG acknowledges the important contribution being made by SGRESP to improving the understanding of pelagic fish dynamics within an ecosystem context. Members of HAWG made 4 contributions to SGRESP:

- i. North Sea herring (see WD3)
- ii. North Sea sprat.
- iii. Celtic Sea herring
- iv. VIa S VIIbc herring

These contributions covered the migrations, spawning and feeding of herring and sprat and a description of the recent population dynamics and the long-term trends in the fish stocks.

1.4.4 HERGEN [EU project]

HERGEN: Conservation of diversity in an exploited species: spatio - temporal variation in the genetics of herring (Clupea harengus) in the North Sea and adjacent areas. EU-project under the Quality of Life and Management of Living Resources programme, 5.1.2. Sustainable fisheries and aquaculture - Scientific basis of fisheries management (QLRT - 2000 – 01370).

1.4.4.1 Estimation of genetic differentiation among spawning aggre gations

Microsatellite DNA based analyses were carried out examining the spatial genetic structure of Atlantic herring in the West of Scotland, North Sea, Kattegat, Skagerrak and Western Baltic. The results obtained will be reported in two scientific publications. The first study (reported in Mariani et al.) concerns structure within the North Sea and the English Channel. This study shows similarities within herring in the North Sea but with underlying genetic substructure. Overall, a signal of isolation by distance is detected, signifying that gene flow is higher among neighbouring spawning components than between geographically distant spawning components.

The second study (reported in Bekkevold et al.) compares genetic differentiation among ten spawning components sampled along a transect from the eastern North Sea to the western Baltic (Rügen). The study indicates low differentiation among three spawning components within the Skagerrak. Spawning components from the Limfjord, the Kattegat, the Kolding Fjord and the Lillebælt (all in the inner Danish waters) generally exhibit significant differentiation. Levels of differentiation between Skagerrak samples and samples from the inner Danish waters are relatively high (and highly significant) in all pair-wise comparisons, indicating a strong reproductive barrier between Skagerrak populations and populations spawning south of Skagerrak. Samples from Rügen exhibit significant differentiation from Kattegat samples and

from most of the samples from 'neighbouring' Danish spawning components. Herring components within the Kattegat/Western Baltic area are thus indicated to exhibit much higher levels of differentiation, compared to components within the North Sea. The generality of the pattern indicating that early spawning Rügen herring are reproductively isolated from fish spawning later in the same location remains unknown. A strong signal of isolation by distance is observed across the analysed samples, which represent the entire transition zone between the highly saline and stable North Sea and the brackish and temperature variable Baltic Sea. When environmental differences among spawning sites are taken into consideration in a test of the relationship between genetic differentiation, geographic distance and differences in environmental parameters on spawning sites, salinity differences yield a higher explanatory power than geographic isolation per se. The implication is that population components experiencing different salinity conditions on spawning sites, also exhibit genetic differentiation, and suggests a role for local adaptation to spawning at low salinity in the Baltic.

1.4.4.2 Determination of composition of mixed feeding aggregations using genetic Mixed Stock Analysis

Genetic mixed stock analysis was performed on random samples from mixed feeding aggregations from Shetland and across Skagerrak for two consecutive years in order to quantify the proportions of fish from the various regional spawning components that contribute to mixed aggregations found on common feeding grounds in areas targeted by major fisheries in the North Sea and the Skagerrak/ Kattegat. The analysis was based on microsatellite DNA genotype frequency information obtained for individuals from the mixed stocks and from the spawning samples. Contributions from each of the four regional areas could be estimated with good precision

- v. North Sea (including Norwegian Spring spawning components)/English Channel
- vi. Skagerrak
- vii. Kattegat/inner Danish waters (a "Kattegat-Western Baltic" group)
- viii. Rügen

Simulation analyses indicated that presence-absence of components from Rügen and Kattegat/inner Danish waters can be determined.

Mixed-stocks in summer in Skagerrak

Analyses operating with three baseline regions generated stock estimates for spatially separated Skagerrak samples showing that individual samples were made up of varying proportions of individuals of North Sea/Skagerrak/Western Baltic origin, and that individual stock composition estimates were highly correlated with the age distributions of the sampled fish. Samples mostly containing juveniles mainly originated from the North Sea, whereas samples consisting mainly of adults contained high proportions of spring spawners of Kattegat-Western Baltic origin. An overall estimate based on genetic information pooled across spatial samples showed that in summer stocks were made up of near equal proportions of North Sea autumn spawners and spawning components from the Kattegat-Western Baltic components, whereas local Skagerrak spawning fish exhibited low abundance or were absent. This pattern was consistent across two years.

Mixed-stocks sampled in winter from coastal Skagerrak

Samples taken in winter in more coastal areas of northern IIIa exhibited a very different stock composition pattern. Here, adult spring spawners of local origin made up an estimated 40-65% of the stocks (estimates varied among samples and years). Whereas most of the remaining individuals were juvenile North Sea autumn spawners, the analysis also identified low but significant contributions from both juvenile and adult spring spawners from the Kattegat-Western Baltic group.

Mixed-stocks in winter from coastal Skagerrak: analyses by spawning type

Analyses where individuals were discriminated based on their spawning type (from otolith microstructure) showed good correspondence between spawning type and expected geographical origin.

Mixed-stocks in summer around Shetland

Mixed stock estimates from samples from Shetland, taken in July 2002 and 2003 showed very high contributions for herring of North Sea origin (composition estimates were both close to 100%), and there was no evidence for contributions from spawning components from Skagerrak, inner Danish waters or Rügen. The resolution of the genetic markers used in this study did not allow for estimates of contributions from individual spawning populations within the North Sea.

1.4.5 WESTHER [EU project]

WESTHER: A multidisciplinary approach to the identification of herring (*Clupea harengus* L.) stock components west of the British Isles using biological tags and genetic markers. Q5RS-2002-01056 (2003-2005).

WESTHER's overall goal is to describe the population structure of herring stocks distributed from the south-west of Ireland and the Celtic Sea to the northwest of Scotland. To achieve its goal WESTHER has four research objectives: (i) estimation of genetic and phenotypic differentiation between spawning aggregations; (ii) determination of stock origins and life history of juveniles; (iii) determination of composition of feeding aggregations and (iv) improved guidelines for the conservation and management of biodiversity and stock preservation. The Project started officially on January 1st, 2003.

Altogether 2004 was a more productive year than 2003. Most of the sampling was successful. Four "mixed" adult aggregations were sampled, one more than originally intended and all of the major spawning areas were successfully sampled, giving a wider coverage than in 2003.

Five of the eight analytical workpackages produced enough data to enable initial analyses of spawning population differentiation, and the relation of juveniles and non-spawning aggregations to spawners in some cases. The research using parasites as biological tags enables the different life-stages to be linked; the other workpackages allow determination of the most important indicators of differentiation between spawners. These indicators will then inform mixed stock analyses of non-spawning adults and juveniles. The use of a number of different methods results in a broader analysis of different facets of population structure than a single method would allow.

To date, the research on using parasites as biological tags has yielded the most results, with more working hypotheses produced than from other workpackages. Results include a new host record for herring, and linkage of different life-stages of herring in different areas. For example, fish that spawn in winter off the north coast of Ireland have been linked to juveniles on Stanton Bank to the north of the area, and to mixtures of adults in the local sea area off the north of Ireland (VIa(S)). In contrast, autumn spawners off the north-west coast of Scotland do not appear to be recruited from coastal nurseries either to the south of the spawning grounds, or from the Scottish east coast.

However, Scottish spring spawners caught slightly further south appear to be recruited entirely from Scottish coastal nursery grounds.

Sampling will be completed by the end of March 2005. WESTHER agreed that all samples taken in the first twelve months will be analysed by the end of March.

1.4.6 Linking Herring 2008 [ICES/GLOBEC sponsored symposium]

ICES and Globec are sponsoring a symposium in 2008 in Galway on herring as a key component of some ecosystems called "Linking Herring". The symposium is also supported by The Marine Institute Norway, The Netherlands Institute for Fisheries Research and The Marine Institute Ireland. The symposium will act as a forum to bring together existing knowledge on herring, to highlight new issues and to pin point inadequacies in our understanding of the role of herring in the dynamics of temperate seas. The symposium will be highly applied in nature, specifically requesting contributions that increase our understanding of ecological role of herring, the variability of production and the impact of source of change on this major pelagic species. Members of HAWG and others with interests in herring will be invited to contribute to the symposium. At present the scientific and managing committees have not been appointed.

The recent success of ICES symposia on the interaction of key ecological species (e.g. capelin and salmon) show that such symposia, can be highly productive and advance the ICES mission towards goals 1 to 4 of its strategy. Bearing these successes in mind, a symposium on the role and interactions of herring would be very pertinent for ICES. Herring are a key high biomass fish in many temperate seas within the ICES area. They are both predator and prey. Herring has a very long association with ICES, with its study and management being at the heart and initiation of the organisation. The last ICES symposium on herring was in 1978. It is aimed to produce a synopsis that integrates the findings of the symposium, which will be of use to scientists and managers.

The Theme Sessions will include:

- i. *Herring in the middle-* the trophic and ecological interactions and impacts of herring
- ii. *Managing Change* management and exploitation of herring in a dynamic environment, within the context of long term change
- iii. *Variable Production* particularly the role of reproduction, recruitment and life history strategies.
- iv. Population Integrity- the integrity of stocks and the drivers of migration
- v. *Counting herring* qualitative and quantitative estimation of herring and its application.

1.4.7 Sprat age reading exchange and Workshop

An age reading workshop was organised by Norway in December 2004 (ICES, 2003). Prior to the meeting an otolith exchange was organised to detect the problems in age reading. The exchange indicated that an improvement in the precision level of age reading was required. Younger fish were more difficult to be interpreted. This indicates that a reduction in the age reading bias is required.

Based on the results of the exchange it appeared to be possible to achieve reliable age readings for North Sea/Skagerrak sprat in future, if it can be proven that sprat always produces an opaque growth zone in the year it is born and that by age reading the otoliths of sprat, the fish can be assigned to a certain year class.

After discussion of the results, the WS re-read a sub-sample of the otoliths. Most readers still demonstrated difficulties in determining annual ring of age group 1 (highest CV). The CV is

lowest for age group 2 and increases again for age group 3. This indicates that readers are uncertain in determining the first annual and again become uncertain at the time the annual growth increment becomes narrow at age 3.

It was recommended that:

- age-validation should be performed in order to confirm the validity of the ageing method used (confirm the periodicity of deposition of the translucent ring, microstructures), to investigate the time of deposition of the translucent ring for each age-class and to determine the spawning time
- measure L1 in sprat otoliths from the various areas to establish the position of the first annual translucent zone (the range in the area)
- not to consider fish length in age estimation, at least not for the first reading
- to have a next exchange in 2007, followed by a WS if necessary

1.4.8 Planning Group on Commercial Catch, Discards and Biological Sampling [PGCCDBS]

The ICES Planning Group on Commercial Catch, Discards and Biological Sampling [PGCCDBS] met in Oostende, 1-4 March to:

- review the recommendations of the EU regional Data Collection Coordination Meetings and address the future of the PG in light of the role and involvement of non-EU countries,
- b. propose sampling methodology for fleet/fishery based data collection;
- review existing information and propose sampling strategies for recreational fisheries:
- review national descriptions of small scale fleets by country and evaluate the strategies used by different countries to obtain basic information for management purposes;
- e. review the possibilities of using shared ALKs;
- f. review the reports from the age-reading exchanges and workshop and identify on a regional basis the candidate stocks and species requiring improved ageing;

The meeting was attended by 39 participants from 18 countries and representatives from the EU Commission, DG FISH.

ToR a): During September 2004 and in January 2005 Regional Coordination Meetings (RCM's) organised by the EU Commission were held (see sec. 1.4.9). Non-EU countries were invited to participate in these data collection planning group meetings. The PGCCDBS expressed its support for having the RCM's, though the PG found it was very important to maintain the PG coordination between the different regions as well ensure same data quality in e.g. age readings, sampling methodology. Furthermore, the PG recommended that the PG could be the forum for discussing mythological and technical issues and how these could be implemented.

ToR b): This issue created intensive discussion on fleet/fisheries/metier definitions despite the guidelines given by ICES (ICES, SGDFF 2003, 2004). At a workshop for fisheries economists organised by the EU Commission other fleet/fisheries/metier definitions were set. A number of national fishery/fleet based data collection programmes were presented to the PG. The general conclusion was that closer cooperation and coordination of data collection are needed as many more cells (quarter, fleet, fishery, area) have to be sampled. Without this cooperation there is a risk of having too many empty cells.

The EU Commission has decided that within the frame of the data collection programme an EU coordinated workshop on fleet/fisheries/metier data collection will be held in Nantes, France in May 2005.

ToR c): In some countries data collection programmes for recreational fisheries have been carried out. The EU data collection regulation prescribes that data collection programmes have to be conducted for tuna fish and salmon. From 2006 and onward, information on the recreational fishery on cod should be collected.

Information on how this challenge in collecting information from the recreational fishery has been dealt with in the U.S.A was presented to the PG. This information and experience can be very useful for the European countries and the approaches used in the U.S.A. could be used as an inspiration. There is no doubt, that data collection will be resource intensive.

ToR d): Most participants presented their present data collection on the small scale fishery. In all countries data collection is very dependent on the EU control regulation (ECC Reg. 850/1998) and other national regulation. Still, uncertainty on how to define "small scale fishery" exists. Therefore, the PG decided to recommend to the EU Commission that the planned workshop on small scale fisheries should be postponed to the autumn of 2005. At that time the findings from workshop fisheries/metier definitions should be agreed and available. An EU coordinated workshop on small scale fisheries data collection will be held in Kavala, Greece in the September/October 2005.

ToR e): Analysis on comparison of ALK's have been carried out for a number of species. On the background of present information the PG recommended further analysis to be carried out. A software developed for the purpose of analysing ALK's was distributed. PG participants were encouraged to carry out analyses on their national data as well as data store in international databases.

ToR f): During 2004 four age reading workshops have been held; sprat, hake, anglerfish and megrim. The agreement between readers for hake and anglerfish is low and therefore uncertainty on input data, such as estimated catch in numbers, for stock assessment purposes may be uncertain. In 2005 four age reading workshop on herring, whiting, sardine and blue whiting will be held.

The PG also reviewed the remarks on the assessment input data for the 2004 assessment WG's. All Assessment WG reports were scanned for data quality and data requirement remarks and for each stock a data sheet has been filled in. An annex with these data sheets is attached to the PGCCDBS 2004 report. The data sheets for the HAWG 2005 are given as table (1.5.3 to 1.5.10)

1.4.9 EU regional meetings on data.

The EU Commission decided in 2004 within fisheries data collection to form a counterpart to the Regional Advisory Committee's. These Regional Coordination Meeting's (RCM's) were established for the Baltic, the North Sea, the Western Areas and Atlantic and for the Mediterranean.

The members of the RCM's are the National Correspondent, one biologist and one economist from each country. The idea of establishing the RCM's was to have a forum where coordination of the fisheries data collection could be discussed and agreements could be made. It should not be a forum where detailed technical issues should be discussed but a forum where agreements on who is doing what and also potential financial issues agreed.

The RCM reports can be found as Annexes to the ICES, PGCCDBS 2005 report.

1.4.10 Study Group on Management Strategies [SGMAS]

A brief overview of the work done by the Study Group on Management Strategies, which met in Jan-Feb. 2005, was presented to the group. It was noted that the report from the SGMAS gives an overview of terminology and concepts, of types of stocks and fisheries, checklists for

evaluation of management strategies and standards for simulation of management strategies in general and harvest control rules in particular. Examples of previously agreed management strategies and how they were developed are given in the report from the SGMAS, including the North Sea herring and the Blackwater herring.

Of particular interest to the group is the management of stocks where annual updated assessments cannot be provided or are considered unreliable, but where there still is a good deal information on the biology and dynamics of the stocks. This problem, which the SGMAS plans to deal with more extensively at its next meeting, applies to most of the herring stocks west of the British Isles. Hence, the development by the SGMAS in this field will hopefully be useful for the HAWG, and current work by the HAWG on management of these stocks will be of particular interest to the SGMAS.

1.4.11 Exchange of maturity photos.

Doubts and difficulties in the maturity staging of herring have been discussed in PGHERS since the end of the 1990s and different measures have been discussed to improve the confidence in the classification. In 2004 PGHERS (ICES, 2004b) agreed that an exchange of digital images should be carried out before the start of the acoustic surveys at the end of June.

A selection of 72 digital images was prepared from a collection of Dutch, Irish, Norwegian and Scottish pictures, and distributed digitally to all the laboratories participating in the summer acoustic surveys. The exchange series covered a whole spectrum of maturity stages. In the acoustic survey for the North Sea herring, scientists use either an 8-point or a 4-point scale for maturity classification (ICES 2004b) and in this exercise were asked to use the scale they normally use.

The main purpose of the exchange was to:

- i. study the usefulness of digital photos as a tool for classification of maturity stages
- ii. analyse the agreement of maturity classifications between the participants.

Three analyses were made, based on a) classification according to the 8-point scale, b) classification according to the 4-point scale (and those from the 8-point scale merged into 4-point scale) and c) all merged into immature and mature. A spreadsheet for a standardised analysis of the age reading comparisons, (www.efan.no) was used for the analysis. The overall results from the three sets were as shown in the following text table:

Mat-scale	% agreement	% CV	N readers
8-point	65.4	23.7	13
4-point	86.3	18.1	14
2-point	92.1	16.4	14

Improvements in the precision were noted going from an 8-point classification to a 2-point classification, as reported from the surveys. However, the overall CV was still high (16.4%) and it is recommended that the national laboratories put some effort into improving the confidence in maturity classifications of herring. An exchange exercise should be carried out every three years, beginning in 2007.

1.5 Commercial catch data collation, sampling, and terminology

1.5.1 Commercial catch and sampling: data collation and handling

Input spreadsheet and initial data processing. Since 1999 (catch data 1998), the working group members have used a spreadsheet to provide all necessary landing and sampling data. The current version used for reporting the 2004 catch data was v1.6.4. All but one nation provided

commercial catch data on these spreadsheets, which were then further processed with the SALLOCL-application (Patterson et al., 1997). This program gives the needed standard outputs on sampling status and biological parameters. It also clearly documents any decisions made by the species co-ordinators for filling in missing data and raising the catch information of one nation/quarter/area with information from another data set. This allows recalculation of data in the future (as done by SG REDNOSE in 2003, ICES 2003/ACFM:10, and as will have to be done when the new ICES InterCatch database is released, see below), choosing the same (subjective) decisions made today. Ideally, all data for the various areas should be provided on the standard spreadsheet and processed similarly, resulting in a single output file for all stocks covered by this working group. Data submission in 2005 went smoother than ever before, all but one nation used the spreadsheets and data were almost error-free. However, some institutes delivered their data very late.

More information on data handling transparency, data archiving and the current methods compiling fisheries assessment data are given in the stock annex 2. To facilitate a long-term data storage, the group stores all relevant catch and sampling data in a separate "archive" folder on the ICES network, which is updated annually. This collection is supposed to be kept confidential as it will contain data on misreporting and unallocated catches, and will be available for WG members on request. Table 1.5.1 gives an overview over data available at present, and the source of the data. Members are encouraged to use the latest-version input spreadsheets if it is needed to re-enter catch data. Figure 1.5.1 shows the separation of areas as used for the long-term storage of data.

Future developments: The ICES InterCatch database. In this section of the report, since 1999, the WG has stated that the handling of catch data is considered as a priority issue for quality control, as the quality of the input data from commercial sampling has proven to be crucial for the quality of the whole assessment procedure. ICES has been asked repeatedly to develop a database application for the proper handling and storage of fisheries catch (-at-age) data. This is also regarded to be a prerequisite for the use of fisheries data for multifleet/multispecies advice. Following generous funding by Norway in 2002, ICES has recently started to develop such a database, called "InterCatch". Draft user specifications are now available, and it is expected that a first version for testing by all WGs or stock coordinators is released at the Annual Science Conference 2005. The thoroughly tested system is planned to be up and running at the start of the WG season 2006, with HAWG being the first WG to use it. All WGs were asked to contribute, namely by delivering fleet and stock definitions, specifications for WG specific inputs (data types needed for specific assessments – with dimensions, level of disaggregation, limits for initial validity checks, stock extraction rules etc.). The WG discussed issues related to the database development briefly at this year's meeting. Information requested by the ICES data centre is given in Table 1.5.2. (based on WD 7). HAWG welcomes ICES' initiative and again offers any possible support in the future. The group reiterated that the database should provide an opportunity to clearly track changes of "official" landings made by WG members to compensate misreported or unallocated landings or discards. This would, however, require means to keep some of the national disaggregated data confidential in order to protect their sources. Further, a transparent and effective handling of information obtained from market sampling in foreign ports should be possible. As the application should be usable by all WGs and all stock coordinators, platform independency is regarded to be a crucial issue for the acceptance of the new system. In this respect, the WG expresses concern that the development outlined at present heavily relies on software of a single commercial vendor. If the new system is not platform independent, the WG will not be able to test the software after initial release, and to use it for data collation at the 2006 meeting. The WG therefore encourages the ICES data centre to assure that access to InterCatch is platform-independent, if not using open source software.

1.5.2 Sampling

Quality of sampling for the whole area. The working group again produced a map indicating the level of catch sampling by area for all herring stocks covered by HAWG (Figure 1.5.2). The map indicates that the sampling level (in terms of fraction of catch sampled and number of age readings per 1000 t catch) is very different for the various areas. Further details of the sampling quality can be found by stock in the respective sections (Sec. 2.2.4 for North Sea herring, 3.2.6 for Western Baltic Spring Spawners, 4.2.3 for Celtic Sea and VIIj herring, 5.2. for VIa(N) herring, 6.2.2 for VIa(S) and VIIb,c herring, 7.2.2 for Irish Sea herring).

The EU sampling regime. HAWG has recommended for years that sampling of commercial catches should be improved for most of the stocks. The EU directive for the collection of fisheries data was implemented in 2002 for all EU member states (Commission Regulation 1639/2001). The provisions in the "data directive" define specific sampling levels. As most of the nations participating in the fisheries on herring assessed here have to obey this data directive, the definitions applicable for herring and the area covered by HAWG are given below:

Area	samplii	ng level per 1000 t catch	l
Baltic area (IIIa (S) and IIIb-c)	1 sample of which	100 fish measured and	50 aged
Skagerrak (IIIa (N))	1 sample	100 fish measured	100 aged
North Sea (IV and VId):	1 sample	50 fish measured	25 aged
NE Atlantic and Western Channel ICES sub-areas II, V, VI, VII (excluding d) VIII, IX, X, XII, XIV	1 sample	50 fish measured	25 aged

There are some exemptions to the above mentioned sampling rules if e.g. landings of a specific EU member states are less than 5 % of the total EU-quota for that particular species.

The process of setting up bilateral agreements for sampling landings into foreign ports has started and is beginning to yield results. However, more of these agreements have to be negotiated, especially between EU and non-EU countries, to reach a sufficient sampling coverage of these landings.

HAWG reviewed the quality of the overall sampling of herring and sprat for the whole area. There is concern that the present sampling regime may lead to a deterioration of sampling quality, because it does not assure an appropriate sampling of different metiers (each combination of fleet/nation/area and quarter). Given the diversity of the fleets harvesting most stocks assessed by HAWG, an appropriate spread of sampling effort over the different métiers is more important to the quality of catch at age data than a sufficient overall sampling level. The EU data directive appears to not assure this. The WG therefore recommends that all metiers with substantial catch should be sampled (including by-catches in the industrial fisheries), that catches landed abroad should be sampled and information on these samples should be made available to the national laboratories.

Comments to sampling quality of the different herring and sprat stocks are given in Tables 1.5.3 to 1.5.10. Most of the issues raised her have also been addressed by the Planning Group on Commercial Catch, Discard and Biological Sampling (see Section 1.4.8.).

1.5.3 Terminology

The WG noted that the use of "age", "winter rings" and "rings" still causes confusion outside the group (and sometimes even among WG members). The WG tries to avoid this by consequently using "rings" or "ringers" instead of "age" throughout the report. It should be observed that, for autumn spawning stocks, there is a difference of one year between "age" and "rings". Further elaboration on the rationale behind this can be found in the stock annex 2.

1.6 Methods Used

The main assessment tools used by this WG is ICA (Patterson, 1998, Needle 2000) which is a separable model over a recent number of years and a conventional VPA over the earlier part of the time-series. This model appears to behave well on the stocks considered by this WG. However, for some stocks additional methods need to be used, e.g. for herring caught in Divisions VIaS and VIIbc where no reliable tuning data are available. For North Sea sprat ageing is considered to be problematic therefore an exploratory assessment is carried out using Catch Survey Analysis (CSA, Mesnil 2003). Both XSA (Darby & Flatman, 1994; Shepherd, 1999) and SURBA (ICES CM2003/D:03; Needle 2004) were used for data exploration and for comparisons with ICA.

Short term predictions for the North Sea used MFSP that was developed three years ago in the HAWG (Skagen; WD to HAWG 2003). Other short term predictions were carried out using the MFDP v.1a software.

1.7 Discarding by Pelagic fishing Vessels

In many fisheries, fish, invertebrates and other animals are caught as bycatch and returned to the sea, a practice known as discarding. Most animals do not survive this procedure. Reasons for discarding are various and usually have economic drivers:

- · Fish smaller than the minimum landing size
- · Quota for this specific species has already taken
- · Fish of undesired quality (high-grading)
- · By-caught species of no commercial value

Theoretically, the use of modern fish finding technology used to find schools of fish should result in low by-catch. However, if species mixing occurs in pelagic schools (most notable of herring and mackerel), non-target species might be discarded. Releasing unwanted catch from the net (slipping) or pumping unsorted catch overboard also results in discarding.

Discarding of herring in the pelagic fisheries was considered not to be a large problem, with discards below 5%, estimated by onboard observer programmes. In the area considered by HAWG, only two nations reported discards from their fleets in 2004. For those nations, discard figures were raised to national landings (based on the spatial and temporal distribution of the fleet), and used in the assessment of North Sea autumn spawning herring (UK/Scotland and Germany, see Section 2.3) and VIaN (UK/Scotland, see Section 5.1.3). All other nations did not report notable amounts of discards of herring in the pelagic fisheries, either because they did not occur, catches were not sampled for discards or difficulties with raising procedures. No discard estimates for the total international catch were calculated.

The inclusion of discarded catch is considered to reduce bias of the assessment and thus give more realistic values of fishing mortality and biomass. However, they might also increase the noise in the assessment because the sampling level for discards is usually lower than that for landings (Table 1.7.1, 1.7.2). This is, as for sampling of landings, caused by the large number of different metiers in the pelagic fishery and the difficult to predict behaviour of the fisheries (in terms of target species and spatial and temporal distribution). Raising discard estimates to the national landings might result in a higher bias than an area based estimate of discards from

the total international fleet, if sampling is insufficient. HAWG therefore recommends that the development of methods for estimating discards be based on a fleet based method, rather than on a national basis.

1.8 Ecosystem considerations, sprat and herring- response to WGRED and SGRESP.

HAWG welcomes the moves within ICES to attempt to reconcile the single species advice within an ecosystem context. It is important when considering ecosystem advice that the quality and robustness of the science is supportable and the advice is able to withstand the rigors of scientific and stakeholder scrutiny. Measures and objectives must be testable and based on high quality science that is defensible to the non-scientific community.

1.8.1 Ecosystem Areas

HAWG considers it productive to break up problems into tractable components and acknowledges that ecosystems from different regions vary from each other. However, the setting of rigid boundaries between neighbouring seas worries HAWG.

With regard to the WGRED descriptions of eco-regions, it is obvious that the demarcation of boundaries between regions is problematic and must be based on certain criteria that may be contentious, e.g. boundaries of the North Sea. Some limits of the WGRED eco-regions contradict well established definitions, e.g. the separation between North Sea and Baltic. The criteria used for the selection of these regions are not transparent to HAWG.

Even if the suggested eco-regions may fit for some demersal stocks, many pelagic ones migrate among areas. In addition currents have an impact on fish distribution, especially for early life stages, and supporting exchange between areas. Thus the classified eco-regions should not necessarily be considered as suitable areas for pelagic management purposes.

1.8.2 North Sea

HAWG notes the comments from WGRED about the decline in sandeel, Norway pout and the copepod *Calanus finmarchicus* abundance in the North Sea. It also acknowledges that the plankton community in the North Sea has shifted to a dominance of more "southerly" species, as shown by CPR data (Beaugrand et al., 2002, Reid et al., 2003). Both Calanus and juvenile sand eels are common prey of herring and recent evidence from the Baltic has shown that juvenile herring positively select *Pseudocalanus* and *Temora* and avoid eating *Acartia* (Casini et al., 2004). *Acartia* is associated with summer blooms and warmer temperatures as shown by Gowen et al (1998).

The individual fish from the strong 2000 year class of herring have been smaller in size and are less mature at age. This suggests that either more slower-growing fish have survived in that year class or that the ecosystem has failed to provide enough food to allow the full potential growth for that cohort i.e. that food has been limiting for that cohort. This cohort grew well up to 1 wr of age.

In terms of the impact of a high biomass of herring on the North Sea ecosystem, some studies are ongoing, but more resources are required to obtain new estimates of stomach contents and feeding by sprat and herring. With low sandeel and *Calanus* abundances, the herring may well be having a stronger impact than in the previous last 2 decades. However a high biomass of herring may also be providing an alternative prey source to piscivores such as horse mackerel and Minke whales (Olsen & Holst, 2001) reducing the pressure on sandeel. These last three sentences are very speculative and if the quantitative trophic-complexities of the system are to considered a priority by ICES, more resources need to be spent on understanding the

trophic interactions in the North Sea and developing spatial and temporal models of trophic dynamics in the system.

The production of herring has increased since the collapse caused by overfishing in the 1970s (Figure 1.8.1) and is dominated by the growth in 1wr fish. The methods used to determine these productions are described in WD 21, and based on that of Dutil & Brander (2003). Surplus production has been of the order of 700 k tonnes for the last 25 years and the recent positive net production has lead to an increase in available herring biomass in the system.

Little analysis is currently taking place into the relative roles of sprat and herring as 'sinks of biomass", predators and prey within the southern North Sea. The interactions of the two species have been shown to be very dynamic in the neighbouring Baltic Sea (Mollmann & Koster, 2002). With the decline in sandeel and other planktivorous fish, HAWG would support further studies into the interaction and associations (or not) of herring, sprat, anchovy and pilchard (sardine).

Kattegat and Skagerrak is also considered an important area for herring by HAWG, it supports both local spawning populations and is the major nursery ground for North Sea herring. The impact of the higher saline inflows through this area into the Baltic Sea in recent years on the resident herring populations is at present unknown. Studies presented to HAWG in 2005 about the HERGEN project suggest that salinity may play a role in the genetic integrity of local spawning components.

Most herring fisheries deploy gear that is deployed clear of the seabed. The impact of gravel extraction on the conservation and productivity of herring is still unclear, and there are virtually no studies to provide evidence at present (CM2003/ACFM:17). The limited evidence available at present records no incidences of cetacean mortality due to pelagic trawling (0 catches observed out of 218 pelagic hauls by commercial trawlers from 1999-2004). There are also very few other by-catches of fish, beyond the targeted fisheries of herring, mackerel, horse mackerel and blue whiting.

1.8.3 Celtic Seas

WGRED did not look at the Celtic Seas in great detail, although SGRESP has considered the region. Across the region information on the comparative dynamics of sprat and herring, particularly in the areas used by juveniles, may prove useful to HAWG. Information on the variability in hydrography, and its influence on larval drift may also be of benefit. In the region, there is no evidence to support the likelihood of wide scale catching of cetaceans by vessels targeting herring. As in the North Sea, there is a severe paucity of data on herring feeding and stomach contents.

Within the Celtic Sea itself, HAWG would like information on the trends in planktonic productivity and recent changes in temperature and related hydrography that may help explain the changes seen in Celtic Sea herring. It should be noted that Celtic Sea herring is the second most southerly population of herring exploited in Europe and thus it may be more effected by sea warming.

Similar requests are made for the continental shelf west of Scotland and the Irish Sea. HAWG would like information on planktonic productivity of the region and any evidence for shifts that coincide with the years of higher herring productivity in the 1970s, particularly in the context of increased yield of recruits per spawner.

Factors that may interest SGRESP and WGRED, include the recent change in the maturity at age ogive in Irish Sea herring. In certain years, the proportion mature 1wr fish (almost 2 years old) can be higher than 30%, and in 2004 100% of 2wr fish were mature.

Despite recent evidence from WESTHER and HERGEN that there is little genetic differentiation between the stocks, their phenotypic characteristics and population dynamics are different. A comparison of the relative trends in surplus production indicates that after the collapses due to overfishing in the 1970s, the Celtic Sea shows a very different pattern compared to both the west of Scotland and the Irish Sea stock (Figure 1.8.2, methods in WD21). The Celtic Sea stock appears to have been more dynamic in terms of surplus production (biomass available to fish) than the stocks further to the north.

1.9 Stock overview

At HAWG, a total of eight herring stocks and three sprat stocks are considered in the area south of 62°N. Analytical assessment could be carried out for four of these eleven stocks. Results of the assessments are presented in the subsequent sections of the report and are summarized below and in Figures 1.9.1 - 1.9.3.

North Sea autumn spawning herring is the largest stock assessed by this WG. It has experienced very low spawning stock biomass levels in the late 1970s when the fishery was closed for a number of years. This stock began to recover until the mid-1990s, when it appeared to decrease again rapidly. A management scheme was adopted to halt this decline. Following a period of good recruitment co-occurring with the new management measures, SSB and the proportion of older fish in the stock increased. This gave the opportunity to increase TACs and catch. In recent years, F on the adults has been just below F_{pa} and fishing mortality on the juveniles has been low. Projections demonstrate that stock-size is likely to be decline due to weak incoming year classes.

Western Baltic Spring Spawners (WBSS) is the only spring spawning stock assessed within this WG. It is distributed in the eastern part of the North Sea, the Skagerrak, the Kattegat and the Sub-Divisions 22, 23 and 24. Within the northern area, they mix with North Sea Autumn Spawners. The WBSS herring stock is slowly recovering from the lowest observed SSB level in 1998. Yield and fishing mortality on the adults are considered to have been reduced in the last years.

Celtic Sea herring: The herring fisheries to the south of Ireland in the Celtic Sea and in Division VIIj have been considered to exploit the same stock. For the purpose of stock assessment and management, these areas have been combined since 1982. The fishery in the eastern part of the Celtic Sea was closed in the early eighties due to poor recruitment. Stock assessments have become unstable in the recent past due to fluctuations in recruitment, for which there is no independent measure. In 2005 no final assessment could be produced. SSB and F cannot be precisely estimated. Indications from recruitment in the catch suggests that recruitment in 2003 (year-class 2001) may be the lowest in the series.

West of Scotland herring is currently lightly exploited and with two good year classes the stock is at a relatively high level compared to last 30 years. Earlier data indicate the possibility of larger stock in the 1960s. The stock experienced a heavy fishery in the mid-70s following closure of the North Sea fishery. The fishery was closed before the stock collapsed. It was opened again along with the North Sea. In the mid 1990s there was substantial area misreporting of catch into this area and sampling of catch deteriorated. Recently the area misreporting has reduced to a very low level and information on catch has improved, but in 2004 misreporting increased again. Instability in the assessment has reduced considerably and the assessment shows a relatively stable SSB and a low F over the last 4 years. Recruitment of the 2001 year-class is well below average.

Herring in VIa south and VIIbc are considered to consist of a mixture of autumn- and winter/spring-spawning fish. The winter/spring-spawning component is distributed in the northern part of the area. The main decline in the overall stock since 1998 appears to have taken place on the autumn-spawning component, and this is particularly evident on the traditional spawn-

ing grounds in VIIb. The current levels of SSB and F are not precisely known, as there is no tuned assessment available for this stock. The results of the non-tuned assessment suggest that the SSB may have stabilised at a low level.

Irish Sea autumn spawning herring comprises of two spawning groups (Manx and Mourne). This stock complex experienced a very low biomass level in the late 1970s with an increase in the mid-1980s after the introduction of quotas. The stock then declined from the late 1980s to its present level. During this time period the contribution of the Mourne spawning component has declined. In the past decade there have been problems in assessing the stock. F appears to be at historic low levels in recent years.

North Sea Sprat is the only sprat stock on which an assessment is carried out within this WG. Sprat is a short-lived species. The recruits account for a large proportion of the stock, and the fishery in a given year is very dependent on that year's incoming year class. The size of the stock has been variable with a large biomass in the early 90's followed by a sharp decline. The sprat stock now shows signs of being in good condition.

The main **assessment tools** used by this WG is ICA (Patterson, 1998, Needle 2000) which is a separable model over a recent number of years and a conventional VPA over the earlier part of the time-series. This model appears to behave well on the stocks considered by this WG. However, for some stocks additional methods need to be used, e.g. for herring caught in Divisions VIaS and VIIbc where no reliable tuning data are available.

ACFM in May 2004 has accepted the assessment of North Sea autumn-spawning herring, West of Scotland herring and Baltic spring-spawning herring as full analytical assessments. The other assessments were only considered to be indicative of stock trends.

1.10 HAWG approach to the western stocks

The WG did not have time at this year's meeting to carry out a full evaluation of the western herring stocks (VIa (N), VIa (S), Irish Sea and Celtic Sea), as was suggested by ACFM. The current situation for these stocks is believed to be the following:

Only VIa (N) herring has a separate agreed assessment.

Currently fisheries in the four stock areas are rather distinct.

Stock development for Celtic Sea, Irish Sea is distinct but with mixing juveniles.

Demographically Celtic Sea, VIa (S) and VIa (N) herring have been believed to recruit independently. VIa (N) and VIa (S) were split into two stocks in 1982 based on demographics through a discriminant analysis of catch data.

Historically Irish Sea and VIa (N) appear to have similar historic stock productivity.

Currently there is an EU funded project evaluating the differences among the Western Stocks with a variety of methods, including genetics, life history traits and biological markers (WESTHER). This project is now in the data evaluation phase and will finish in December 2005. A full evaluation of all the data might not be available before by HAWG in 2006.

A combination of the catch data to provide a historic VPA would be relatively straightforward but would provide little benefit over combination of the individual VPAs.

The main benefits for combination of some or all of the area is where either fisheries overlap, as for juveniles in the southern Irish Sea for Celtic and Irish Sea herring, or where stock separation is less distinct for adults in areas VIa (N), Irish Sea and Clyde.

The current main problem for a combined area assessment is the lack of a single source of a comprehensive survey to act as a tuning index.

The WG considers that it would be best to await the results from WESTHER before considering what should be done. If combination of two or more stocks or areas in considered useful, this may require coordination of a suitable survey.

Recommendations 1.11

- HAWG recommends that the new ICES InterCatch database should provide an opportunity to clearly track changes or allocations of "official" landings made by WG members and to compensate for misreported or unallocated landings or discards. This would, however, require means to keep some of the national disaggregated data confidential in order to protect their sources. Further, a transparent and effective handling of information obtained from market sampling in foreign ports should be possible. The WG also encourages the ICES data centre to assure that access to InterCatch is platform-independent, if not using open source software. Action: C. Zimmermann. (from Sec 1.5)
- HAWG recommends that all metiers with substantial catch should be sampled (including by-catches in the small meshed fishery).
- HAWG recommends that similar arrangements, as the obligation implemented by the EU Member States on sampling of landings outside the flag country, to be implemented between all countries. Furthermore, agreements on when and how the sampling country provides sampled data to the flag country should be made in order to make data available for the HAWG
- HAWG recommends that the development of methods for estimating discards be based on a fleet based method, rather than on a national basis. The inclusion of discarded catch is considered to give more realistic values of fishing mortality and biomass. Action: PGCCDBS. (from Sec 1.7).
- To ensure the continuity of the North Sea herring larvae surveys they should be considered for priority 1 EU funding. This survey is providing value for money that is equivalent to the other sources of information used to assess North Sea herring. It should therefore be given the same priority of funding as the other surveys and market sampling data collection schemes.
- HAWG recommends that the existing surveys of herring in the southern North Sea and English Channel be maintained, and that the micro-increment analysis of otoliths (to determine spawning type) is carried out on samples collected during the annual acoustic survey.
- HAWG recommends that the possibility of separating the juveniles caught in the Irish Sea acoustic and ground fish surveys into autumn and winter spawning components based on otolith microstructure and/or length composition is investigated.
- The annual series of IBTS indices on North Sea herring 1-5+ ringers used by the HAWG is an accumulation of the indices retrieved during each years HAWG. While there might have been additions and corrections to data after these retrievals, and while there might be some differences between retrieval procedures throughout the series, HAWG recommends that updated, standardized retrievals are available to the WG at the 2006 meeting.
- HAWG recommends the following timetable for benchmark assessments: 2006 North Sea herring autumn spawners
 - 2007 Western Baltic spring spawners
 - 2008 Celtic Sea herring, VIa North herring
- HAWG notes the third year of weak recruitment in North Sea herring, and that series of poor recruitments have occurred in the past with major implications for the management of the North Sea herring stock. HAWG therefore recommends that studies be initiated into whether the tendency of periodicity in the level of recruitment of autumn spawned herring is linked to changes in the hydrography and/or the biology in the North Sea.

- Table 1.5.1: Available disaggregated data for the HAWG per March 2005 X: Multiple spreadsheets (usually xls); W: WG-data national input spreadsheets (xls);
 - D: Disfad inputs and Alloc-outputs (ascii/txt)

Table 1.5.2 HAWG initial definitions for the new ICES InterCatch database. Note that definitions of fleets and fisheries are currently under development; the list provided here is not final.

1. General

Definitions should apply for all WGs and are therefore predefined (species, catchyear, date of submission/resubmission, nation, contact details, national fleet descriptions, sampling level, catch,...) and general consistency checking should apply

2. WG/Species specific input

3. WG/Species specific validity check:

WGs should choose entry fields relevant for them from an
exhaustive option list (to assure interWG operability)

DCR data aggreg	ation level:					
Temporal and seg	gmentation:	Spatial:				
By quarter and fishing technique		By ICES Division				
WG comments to	the data quality:	WG comments to the data quality:				

The working group has evaluated the spatial coverage of the level of catch sampling by area for all herring stocks covered by HAWG. It was indicated that the sampling level (in terms of fraction of catch sampled and number of age readings per 1000 t catch) is different for the various areas

Given the diversity of the fleets harvesting North Sea Autumn Spawning herring, an appropriate spread of sampling effort over the different fisheries/métiers is important to ensure the quality of the catch at age data The EU data directive (Commission Regulation 1639/2001) does not warrant this. The WG therefore recommends that all fisheries/métiers with substantial catch should be sampled (including by-catches in the industrial fisheries) and that catches landed in foreign ports should be sampled and information on these samples be made available to the national laboratories of the vessel's flag state.

Most of the issues raised her have also been addressed by the Planning Group on Commercial Catch, Discard and Biological Sampling at its meeting in 2004.

WG comments to data requirements:

As the advice on exploitation of the marine fish and shellfish stocks gradually changes from single species advice to multispecies/mixed fisheries advice, it is necessary to obtain catch-atage information by fishery/metier. To facilitate this, HAWG has defined the fisheries that exploit the herring stocks which are assessed by the WG

It is recommended to the regional fisheries data collection coordination and co-operation groups and to the national laboratories to take the WG suggestions for the definition of fisheries into account when setting up sampling schemes for 2005.

It should be noted that this fishery/metier definition is on a lower level of aggregation than defined in the EU data directive. In order to be able to derive multi-fisheries advice it will be necessary to harmonise the data directive accordingly.

Completed by: Jørgen Dalskov	
------------------------------	--

Table 1.5.4 HAWG comments to the sampling of Herring in Division IIIa and the Western Baltic area.

Stock:	Herring in Division IIIa and the Western Baltic area

DCR data aggregation level:			
Temporal and segmentation:		Spatial:	
By quarter and fish	ning technique	By ICES Division	

WG comments to the data quality:

Given the diversity of the fleets harvesting this stock the HAWG recommends that an appropriate spread of sampling effort over the different fisheries/métiers is important to the quality ensure the estimates of catch at age data The EU data directive (Commission Regulation 1639/2001) appears not ensure this. The WG therefore recommends that all fisheries/métiers with substantial catch should be sampled (including by-catches in the industrial fisheries) and that catches landed abroad should be sampled and information on these samples should be made available to the national laboratories.

WG comments to data requirements:

As the advice on exploitation of the marine fish and shell fish stocks gradually changes from single species advice to multi fisheries advice, it is necessary to have data by fishery/metier. As a first step the HAWG has defined the fisheries that exploit the herring stocks which are assessed by the WG

The regional fisheries data collection coordination and co-operation groups as well as the national laboratories are recommended to take the WG suggestion for fishery definition into account when setting up sampling schemes for 2006.

It should be noticed that this fishery/metier definition is on a lower level of aggregation than prescribed in the EU data directive. In order to be able to give multi fisheries advice it is necessary to harmonize the data directive accordingly.

Completed by:	Jørgen Dalskov

Table 1.5.5 HAWG comments to the sampling of Herring in Division VIa North

Stock:	Herring in Division VIa (North)	
WG name:	Herring Assessment Working Group for the Area South of 62 ⁰ N	
WG data aggregation level:		
Temporal and segmentation:		Spatial:
By quarter and fishery/métier		By ICES Sub-division
DCR data aggregation level:		
Temporal and seg	mentation:	Spatial:
By quarter and fishing technique		By ICES Division: VIa (North)

WG comments to the data quality:

The number of samples used to allocate an age-distribution for the VIa (N) catches has steadily decreased from 52 in 2002, 37 in 2003 down to 10 in 2004. This is due to two problems;

- iii. The difficulty of targeting sampling on vessels that fish in this area because these vessels fish in other herring areas and there may be no prior knowledge of the fishing intentions of the vessel before departure from port.
- iv. The area misreporting recorded of catch taken in other in other areas and reported as VIa (N) can result in successfully collected samples being subsequently reallocated correctly to their true area thus loosing numbers of samples from the sampling program.

In the past concern has been raised over the quality of sampling of commercial catch. It was suggested in the 2001 ACFM technical minutes that an analysis of catch by quarter and country might shed some light on the variability in the catch information. In practice the fishery is often dominated by a single quarter catch, and a single country dominates sampling. Thus such an analysis is impossible. Although sampling is relatively poor the analysis indicated that sampling for age information was not the major source of variability in the assessment at that stage.

WG comments to data requirements:

As the advice on exploitation of the marine fish and shell fish stocks gradually changes from single species advice to multi fisheries advice, it is necessary to have data by fishery/metier. As a first step the HAWG has defined the fisheries that exploit the herring stocks which are assessed by the WG

The regional fisheries data collection coordination and co-operation groups as well as the national laboratories are recommended to take the WG suggestion for fishery definition into account when setting up sampling schemes for 2006.

It should be noted the mixing of species in this fishery is not perceived as a problem in VIa (N) and is not a consideration.

PGCCDBS comments to improvement of the data collection:

Closer cooperation in sampling between England, Germany, Netherlands and France (freezer trawler fleet) and an increase in sampling from Scotland.

Table 1.5.6 HAWG comments to the sampling of Herring in Division VIa South and VIIbc.

Stock:	Herring in Division VIa (South) and VIIb,c	
WG name:	Herring Assessment Working Group for the Area South of 62 ⁰ N	
WG data aggregation level:		
Temporal and segmentation:		Spatial:
By quarter and fishery/métier		By ICES Sub-division: Via (South), VIIb,c
	-	
DCR data aggregation level:		
Temporal and segmentation:		Spatial:
By quarter and fishing technique		By ICES Division
WG comments to the data quality:		

The management of the Irish fishery in recent years has tightened considerably and the accuracy of reported catches in recent years is believed to have improved. The level of sampling is quite high relative to three years ago. There is a need, however, to achieve a better coverage of VIIb, especially in the first quarter. Also, better coverage of large RSW trawlers that target this stock spasmodically is required.

WG comments to data requirements:

IT is vitally important that historic and current catch data for herring in industrial fisheries in this area be made available. This may account for considerable unknown mortality.

PGCCDBS comments to improvement of the data collection:

The DCR has to be changed so it has the same segmentation as required by the ICES Assessment Working Group.

Completed by:	Maurice Clarke

Table 1.5.7 HAWG comments to the sampling of Herring in Division VIIa North.

By quarter and fishery/métier		By ICES Sub-division: VIIa			
DCR data aggrega	ation level:				
Temporal and segmentation:		Spatial:			
By quarter and fishing technique		By ICES Division			

WG comments to the data quality:

There was a suggestion that the landings data for herring in Division VIIa(N) were un-reliable between 1998 and 2001. A re-examination of these data by the institute where most of the landings occur, resulted in the conclusion that the landings data for this time period are no more un-reliable than landings data in any adjacent management area. There are still no estimates of discarding or slippage of herring in the Irish Sea fisheries that target herring. Biological sampling of this fishery remains high (approximately 1 sample per 270 t landed, however, there is a suggestion that there may need to be some revisions for the 2003 data. All sampling was undertaken by Northern Ireland.

WG comments to data requirements:

As the advice on exploitation of the marine fish and shell fish stocks gradually changes from single species advice to multi fisheries advice, it is necessary to have data by fishery/metier. As a first step the HAWG has defined the fisheries that exploit the herring stocks which are assessed by the WG

The regional fisheries data collection coordination and co-operation groups as well as the national laboratories are recommended to take the WG suggestion for fishery definition into account when setting up sampling schemes for 2005.

It should be noticed that this fishery/metier definition is on a lower level of aggregation than prescribed in the EU data directive. In order to be able to give multi fisheries advice it is necessary to harmonize the data directive accordingly.

		-				

WG comments to the data quality:

The sampling level in 2004 was lower than in previous years. In Denmark the provisions in the EU regulation 1639/2001 have been implemented. This provision requires 1 sample per 2000 tonnes landed. This sampling level is lower than the guidelines (1 sample per 1000 tonnes) previously used by the HAWG, but as the fishery was carried out in a limited area, the recommended sampling level can be regarded as adequate.

The recommended sampling levels for species composition were achieved.

WG comments to data requirements:

As the advice on exploitation of the marine fish and shell fish stocks gradually changes from single species advice to multi fisheries advice, it is necessary to have data by fishery/metier. As a first step the HAWG has defined the fisheries that exploit the herring stocks which are assessed by the WG

The regional fisheries data collection coordination and co-operation groups as well as the national laboratories are recommended to take the WG suggestion for fishery definition into account when setting up sampling schemes for 2006.

It should be noticed that this fishery/metier definition is on a lower level of aggregation than prescribed in the EU data directive. In order to be able to give multi fisheries advice it is necessary to harmonize the data directive accordingly.

PGCCDBS comments to improvement of the data collection:

The DCR has to be changed so it has the same segmentation as required by the ICES Assessment Working Group.

2.1 The Fishery

2.1.1 ACFM advice and management applicable to 2003 and 2004

According to the management scheme agreed between the EU and Norway, adopted in December 1997 and last amended in November 2004, efforts should be made to maintain the SSB of North Sea Autumn Spawning herring above 800,000 tonnes. An SSB reference point of 1.3 million has been set (=**B**_{pa}) above which the TACs will be based on an F= 0.25 for adult herring and F= 0.12 for juveniles. If the SSB falls below 1.3 million tonnes, the fishing mortality will have to be linearly reduced. A TAC deviation of more than 15% between two subsequent years should be avoided, however, the TAC might be reduced by more than 15% if the parties consider this appropriate.

Since 2002, the SSB is considered to have been above \mathbf{B}_{pa} . From then on, ACFM gave fleetwise catch option tables for fishing mortalities within the constraints of the EU-Norway management scheme. The advice for a sub-TAC on catches in IVc and VIId for 2004 was that it should not increase faster than the TAC for the North Sea as a whole. ACFM thought that a share of 11% on the total North Sea TAC (average share 1989-2002) would be an appropriate guide to distributing the harvesting of Downs herring.

It was expected that fishing at the recommended level would lead to a further increase in the SSB in the short term, mainly due to large recruiting year classes entering the fishery. ACFM noted, however, that catches would have to be reduced from 2006 on to account for the weak year classes seen since 2001.

The final TAC adopted by the management bodies for 2004 was 460,000 t for Area IV and Division VIId, whereof not more than 66,098 t should be caught in Division IVc and VIId. For 2005, the TAC was raised to 535,000 t (by 16%) and the sub-TAC set for Division IVc and VIId was raised to 74,293 t (by 12%, representing a share of almost 14% on the total TAC). Catches of herring in the Thames estuary are not included in the TAC. The by-catch ceiling set for fleet B in the North Sea was 38,000 t for 2004 and was increased by 32% to 50,000 t for 2005. As North Sea autumn spawners are also caught in Division IIIa, regulations for the fleets operating in this area have to be taken into account for the management of the stock (see Section 3). For a definition of the different fleets harvesting North Sea herring see the stock annex and Section 2.7.2.

Following the apparent recovery of the North Sea Autumn Spawning herring, some regulatory measures have been amended in 2004: The total Norwegian quota and half of the EU quota for Division IIIa could be taken in the North Sea. UK/Scotland relaxed its licensing scheme which was put in place in 1997 to reduce misreporting between the North Sea and VIaN. The minimal amount of target species in the EU industrial fisheries in IIIa has been reduced to 50% (for sprat, blue whiting and Norway pout). It is at present unclear whether all of these amendments will be kept for 2005; for Division IIIa, Norway can only take half of its quota in the North Sea, and there is no flexibility for EU vessels.

2.1.2 Catches in 2004

Total landings and estimated catches are given in the Table 2.1.1 for the North Sea and for each Division in Tables 2.1.2 to 2.1.5. Total working group catches per statistical rectangle and quarter are shown in Figures 2.1.1 a-d, the total for the year in Figure 2.1.1e. Each nation provided most of their catch data (either official landings or working group catch) by statistical rectangle.

The catch figures in Tables 2.1.1-2.1.5 are mostly provided by WG members and may or may not reflect national catch statistics. These figures can therefore **not** be used for legal purposes. For corrections applied to and inconsistencies in previous year's data see Section 2.2.3. Denmark and Norway provided information on by-catches of herring in the industrial fishery. These are taken in the small-meshed fishery (B-fleet) under a EU quota by Denmark and are included in the A-fleet figures for Norway. Catch estimates of herring taken as by-catch by other small-mesh fisheries in the North Sea may be an underestimate. The total catch in 2004 as used by the Working Group amounted to 550,100 t. Following the raising of the TAC for herring caught in the North Sea by 15%, the total catch increased by more than 22% compared to last year. By area, catches increased in Division IVa (East) by about 43%, in IVa (West) by 20%, in IVb by 26%, and by only 1% in the southern North Sea (Division IVc and VIId), while the sub-TAC for the latter area was raised by 11%.

Landings of herring taken as by-catch in the Danish small-meshed fishery in the North Sea were much lower than the by-catch ceiling set for Denmark (38,000 t), and have increased by 11% to 13,586 t as compared to last year (Table 2.1.6). In 2004, the Danish sprat fishery was carried out mainly in the second half of the year with by-catches of herring of about 5% (10,100 t). Herring by-catches in the Danish Norway pout fishery were estimated to be less than 8% (700 t), less than 0.9 % in the sandeel fishery (2,400 t) and 3 % in other industrial fisheries (700 t). In the Norwegian industrial fishery, herring by-catch has increased from 3,809 t last year to 4,984 t, mostly due to a relatively high bycatch in the Norway pout and blue whiting fishery in the first quarter. The quarterly distribution of herring by-catches in the Norwegian industrial fishery and its relative share on the total industrial landings are given in the text table below. These figures are counted against the human consumption quota.

Quarter 1	Quarter 2	Quarter 3	Quarter 4	Total
3,502 t	423 t	626 t	434 t	4,984 t
27.9 %	0.6 %	1.5 %	2.4 %	3.5 %

Misreporting of landings taken in the North Sea but reported from other areas such IIa and IIIa, and again from VIaN have significantly increased in 2004. However, while the Norwegian catch officially reported for IIIa is believed to have been taken in the North Sea since 1995, there have been real Norwegian catches in IIIa this year. The estimates of the total amount of misreported (including within-area misreporting) and unallocated catches have increased to about 66,000 t (roughly 12% of the total catch in the North Sea).

Based on WG estimates of total catch, TACs for the human consumption fishery in Subarea IV and Division VIId have been significantly exceeded for several years. This appears to have continued in 2004, when the over catch of TAC was almost doubled to 77,000 t compared to 2003. In the past, the largest relative discrepancies between officially reported landings and WG catch occurred in Division IVc and VIId, where TACs were exceeded by almost 100% between 1996 and 2001 (when the sub-TAC was set to 25,000 t). This has apparently changed in 2004, when the over catch of TAC in the southern North Sea and the Eastern Channel was reduced to only 4%. The majority of excess catch is now taken in IVa and IVb.

The total North Sea TAC excess for the years 1995 to 2004 is shown in the table below (adapted from Table 2.1.6). Since the introduction of yearly by-catch ceilings in 1996, these ceilings have never been exceeded.

Year	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004
TAC HC ('000 t)	440	156	159	254	265	265	265	265	400	460
"Official" landings HC ('000 t) ¹	443	170	162	253	275	267	275	282	414	484
Working Group catch HC ('000 t)	449	196	226	324	318	328	303	331	438	537
Excess of landings over TAC HC ('000 t)	9	40	67	70	53	63	38	66	38	77
By-catch ceiling ('000 t) ³		44	24	22	30	36	36	36	52	38
Reported by-catches ('000 t) ⁴	67	38	13	14	15	18	20	22	12	14
Working Group catch North Sea ('000 t)	516	233	238	338	333	346	323	353	450	550

HC = human consumption fishery

2.2 Biological composition of the catch

Biological information (numbers, weight, length, catch (SOP) at age and relative age composition) on the catch as obtained by sampling of commercial catches is given for the whole year and per quarter in Tables 2.2.1 to 2.2.5. Where available, data are displayed separately for herring caught in the North Sea (including a minor amount of Western Baltic Spring-spawners taken in IVa East), IVa East (total; Western Baltic Spring spawners [WBSS] only – see Section 2.2.2; North Sea Autumn-spawners only), IVa West, IVb, VIId/IVc as well as for North Sea Autumn-spawners (NSAS) caught in Division IIIa, and the total NSAS stock, including catches in Division IIIa.

Biological information on the NSAS caught in Division IIIa was obtained using splitting procedures described in Sec. 3.2 and in the stock annex 2. The total catches of NSAS (SOP figures), mean weights and numbers-at-age by fleet are given in Table 2.2.6. Data on catch numbers-at-age and SOP catches are shown for the period 1995-2004 in Tables 2.2.7 (herring caught in the North Sea), 2.2.8 (WBSS taken in the North Sea, see below), 2.2.9 (NSAS caught in Division IIIa) and 2.2.10 (total numbers of NSAS). Mean weights-at-age are given for 1995-2004 separately for the different Divisions where NSAS are caught (Tab. 2.2.11). Note that SOP catch estimates may deviate in some instances slightly from the working group catch used for the assessment, this year most notably for area IVaW where the SOP catch estimate is 3,400 t higher than WG catch. As no information was available to decide whether numbers or weight was incorrect, SOP figures were not scaled to arrive at 100%.

2.2.1 Catch in numbers-at-age

North Sea catches in numbers-at-age over the years 1990-2004 are given in Table 2.2.7. The total number of herring taken in the North Sea and the total number of NSAS have increased by 18% (to 3.9 billion fish) and by 6% (to 4.3 billion fish), respectively, as compared to last year. 0- and 1-ringers contributed 21% of the total catch in numbers of NSAS in 2004. Fig. 2.2.1. shows the relative proportions of the total catch numbers for different periods (1960-2004, 1980-2004 for the total area, and 2004 for different Divisions). Note that almost 70% of the catch in the southern North Sea consists of the 2000 year class, while catches in the North (IVa) are dominated by the strong 1998 year class. During winter, the 2000 year class appears to be almost absent from some areas in IVaW.

The following table summarises the total catch in tonnes of North Sea autumn spawners. To arrive at the total catch of NSAS, splitting of the catch into NSAS and Western Baltic Spring Spawners has to be done in Divisions IIIa and IVaE. NSAS from IIIa are then added, and

¹ "Official" landings might be provided by WG members; they do not in all cases correspond to official catches and cannot be used for management purposes. Norwegian by-catches included in this figure.

² figure altered in 2000 on the basis of a re-evaluation of misreported catches from VIa North.

 $^{^3}$ by-catch ceiling for EU industrial fleets only, Norwegian by-catches included in the HC figure.

⁴ provided by Denmark only.

WBSS from the North Sea subtracted from the total NSAS catch figure. The final total catch
used for the assessment of NSAS in 2004 was 567,000 tonnes:

AREA	ALLOCATED	UNALLOCATED	DISCARDS	TOTAL	
IVa West	218,427	28,631	15,794	262,852	
IVa East	119,329	-	-	119,329	
IVb	89,898	8,300	1,265	99,463	
IVc/VIId	56,506	11,967	-	68,473	
	Total catch in the	North Sea		550,117	
	Autumn Spawner	Autumn Spawners caught in Division IIIa (SOP)			
	Baltic Spring Spa	wners caught in the North Se	a (SOP)	-7,079	
	Other Spring Spa	wners		-62	
	Total Catch NSA	567,190			

"Other spring spawners" are 62 t of Blackwater herring caught under a separate quota and included in the catch figure for England & Wales, while this year no spring spawners were reported from the commercial catch taken in the Western North Sea.

2.2.2 Spring-spawning herring in the North Sea

Norwegian Spring-spawners and local fjord-type herring are taken in Division IVa (East) close to the Norwegian coast under a separate TAC. These catches are not included in the Norwegian North Sea catch figures given in Tables 2.1.1 to 2.1.6, but are listed separately in the respective catch tables. The amount of these catches varied significantly between less than 500 t in 2004 and 55,000 t in 1997. Coastal Spring Spawners in the southern North Sea (e.g. Thames estuary) are caught in small quantities (usually less than 100 t) regulated by a local TAC. The Netherlands reported increasing catches of Spring Spawners in the Western Part of the North Sea in recent years, which were included in the national catch figures and subtracted from the total catch used for the assessment of NSAS. This year no spring spawners were reported from routine sampling of commercial catch taken in the west.

Western Baltic and Division IIIa Spring-spawners (WBSS) are taken in the eastern North Sea during the summer feeding migration. These catches are included in Table 2.1.1 and listed as IIIa type. Table 2.2.8 specifies the estimated catch numbers of WBSS caught in the North Sea, which are transferred from the North Sea assessment to the assessment of Division IIIa/Western Baltic in 1991-2004.

The method of separating these fish, using vertebral counts as described in former reports of this Working Group (ICES 1991/ACFM:15) is given in Sec. 3 and in stock annex 2. For herring 2-ringers, 3-ringers, and 4+-ringers caught in the 2nd quarter, mean vertebral counts in the transfer area (see Fig. 1.5.1) were used. Samples from the Norwegian catches that have been taken in May and June 2004 were used for the second quarter (Figure 2.2.2). For 1-ringers in the 2nd quarter it was assumed that all fish were autumn spawners. For the 3rd quarter no Norwegian or Danish samples were available for landings from the transfer area, and instead the proportions from samples taken during the Danish acoustic survey in this area (based on otolith examinations) were applied to the age distributions. The resulting proportion of spring spawners and the quarterly catches of these in the transfer area in 2004 are as follows:

QUARTER	1- RINGERS (%)	2- RINGERS (%)	3- RINGERS (%)	4+- RINGERS (%)	CATCH IN THE TRANSFER AREA (T)	CATCH OF WBSS IN THE NORTH SEA (T)
Q 2	0%	28%	21%	3%	33,654	4,533
Q 3	23%	33%	82%	95%	3,099	2,546
total					36,753	7,079

The quarterly age distribution in Subdivision IVa East was applied to the catches of the second and third quarters in the whole area. The numbers of Spring-spawners by age were obtained by applying the estimated proportion by age.

2.2.3 Data revisions

A number of data revisions have been applied to the assessment input data set at last year's WG meeting, specifically following the work of the Study Group on the Revision of Data for North Sea Herring (SG Rednose, ICES 2003/ACFM:10) which reworked catch and catch-atage data for 1995-2001. Further, the splitting between NSAS and WBSS in Division IIIa had been revised last year, based on new information of the distribution of Norwegian catches in Divisions IIIa and IVa(E) for the same period. Splitting data is still not completely reworked for the earlier period and NSAS assessment data could therefore not be updated for 1991 to 1995.

No data revisions were made this year.

2.2.4 Quality of catch and biological data, discards

As in previous years, some nations provided information on misreported and unallocated catches of herring in the North Sea and adjacent areas. Catches made in Division IVa were mainly misreported to Division VIa, IIIa and IIa, but misreporting also occurred from IIIa to IVa, within Area IV, and from Division VIId to IVb. The **Working Group catch**, which includes estimates of discards and misreported or unallocated catches (see Section 1.5), was estimated to exceed the official catch by about 14%. An analysis conducted in 2002 (ICES 2002/ACFM:12) indicated that this figure could be much higher if the mean rate of misreporting and unallocated catch for nations reporting this would be applied to the whole North Sea catch. This corroborates suggestions of the Study Group for Herring Assessment Procedures (ICES 2001/ACFM:22), that a important uncertainty of the total catch figure exists since the reopening of the fishery in 1980.

Discards. Prior to 1998, there was little available information available on herring discards in the pelagic fisheries in the North Sea. Observer sampling programs since 1999 suggested that discarding in these fisheries were less than 5%.. In 2002 for the first time, onboard sampling by two nations observed increased discards of herring in the mackerel fishery in the 3rd and 4th quarter in Division IVa (W). At this time, the quotas for herring were already taken and herring occurred in mixed schools with mackerel. The discard figure finally used for the assessment was 17,000 t. If the same raising scheme would have been used for all fleets involved, discards would have been as high as 50,000 t. However, the behaviour of other than the sampled fleets is uncertain. For 2003, the herring TAC has been increased by 50%, and at the same time the mackerel TAC has been reduced by more than 5%. Sampling of the same fleets in 2003 showed a reduced level of discarding, as was anticipated. Discards again occurred mainly in the mackerel fishery in the 1st and 4th quarter, and to less extent as slippage in the directed herring fishery in the 3rd quarter. The discard figure used in the assessment for 2003 was 4125 t, based on the raised figure for one sampled fleet. In 2004, herring quotas were again increased and mackerel quotas markedly decreased. In spite of this, reported discarding was back to the 2002 level. Three pelagic fleets have been sampled for discards (see Section 1.7); the majority of discards were again reported from the mackerel fishery in IVa in the 4th quarter (11,000 t), smaller amounts were due to slipping/technical failures in the same area in the 3rd quarter. In one fleet, substantial discards occurred in the 3rd quarter in IVa and IVb, when there were clear indications for highgrading: smaller fish was consistently discarded from most of the hauls. If this behaviour would have been raised to the total catch of the fleets believed to be operating in the same way, discards due to highgrading could have been in the order of 19,000 t (WD 6). However, onboard sampling of other vessels in a similar fleet obtained no highgrading (see Section 1.7), which points to the uncertainty of any such raising.

The final figure for discards in 2004 as used in the assessment was 17,059 t, based on the raised discards for two fleets. As discards are likely to occur in all nation's fisheries, this figure is certainly an underestimate. With a higher market value and the availability of bigger fish, and at the same time the strong 2000 year class with comparatively slow growth entering the fishery, there is concern that smaller herring is increasingly discarded earlier in the year when fish could have been landed legally.

In general, **sampling of commercial landings** for age, length and weight has again improved as compared to last year (Table 2.2.12). The European Union implemented a new sampling regime in 2002, obliging member states to meet specified overall sampling levels. This year, 94% of the catch was sampled (2003: 85%), and the number of age readings has again been increased by 28%. It should be observed that "sampled catch" in Table 2.2.12 refers to the proportion of the reported catch to which sampling was applied. This figure is limited to 100% but might in fact exceed the official landings due to sampling of discards, unallocated and misreported catches.

However, more important than a sufficient overall sampling level is an appropriate spread of sampling effort over the different metiers (each combination of fleet/nation/area and quarter). Of 100 different *reported* metiers, only 39 were sampled in 2004 (39%; 2003: 40%). Some of them, however, yielded very little catch. The recommended sampling level of more than 1 sample per 1,000 t catch has been met only for 29 metiers (2003: 34). For age readings (recommended level >25 ageings per 1000 t catch) this is only slightly worse: only 26 metiers appear to be sampled sufficiently (2003: 29). The catch of France, UK/England and Wales, Sweden, Northern Ireland and the Faroe Islands from the North Sea (combined share 13% of the total North Sea catch) has not been sampled. Information on catches landed abroad was again not available or could not be used. While it is known that by-catches of herring in other than the directed human consumption fisheries occur, most countries have not implemented a sampling scheme for monitoring these fisheries.

In this respect, there is still a need to improve the quality of the catch data for the North Sea herring. It appears that in some instances the new EU data collection directive could lead to a deterioration of sampling quality, because it does not assure an appropriate sampling of different metiers. This introduces uncertainties in the biological composition of the catches, which affects the quality of the assessment. The WG therefore recommends that all metiers with substantial catch should be sampled (including by-catches in the industrial fisheries), that catches landed abroad should be sampled and information on these samples should be made available to the national laboratories (see Section 1.5).

2.3 Fishery Independent Information

2.3.1 Acoustic Surveys in VIa(N) and the North Sea in July 2004

Six surveys were carried out during late June and July 2004 covering most of the continental shelf north of 51° 30'N in the North Sea and 56°N to the west of Scotland to a northern limit of 62°N. The eastern edge of the survey area is bounded by the Norwegian, Danish, Swedish, German and Dutch coasts, and to the west by the shelf edge at approximately 200 m depth. The individual surveys and the survey methods are given in the report of the Planning Group for Herring surveys (ICES 2005/G:04). The vessels, areas and dates of cruises are given below and in Figure 2.3.1.1:

VESSEL	PERIOD	Area
FV Enterprise	6 July – 25 July	56°- 60°N, 3° - 7° W
R.V Johan Hjort	8 – 30 July	57°- 61° N, 2° - 6° E
Scotia	1 - 22 July	58 15°- 62° N, 4° W - 2° E
Tridens	28 June – 23 July	$54^{\circ}30 - 58^{\circ} 15$, N, west of 3° E
Walther Herwig III	28 June – 19 July	51° 30' - 57° N, east England / 3° E / 6° E
Dana	29 June – 12 July	North of 57°NS & 56° N, Kattegat east of 6° E

The data has been combined to provide an overall estimate. Estimates of numbers-at-age, maturity ogive and mean weights-at-age are calculated as weighted means of individual survey estimates by ICES statistical rectangle. The weighting applied is proportional to the survey track for each vessel that has covered each statistical rectangle. The data have been combined and the estimate of the stock surveyed is shown in Tables 2.3.1.1-3 by ICES subarea for North Sea autumn spawning herring.

Combined Acoustic Survey Results:

The estimate of North Sea autumn spawning herring SSB is 2.6 million tonnes which is 14,000 millions herring (Table 2.3.1.4). This data series is used as a relative index in the assessment of North Sea herring because the absolute abundance cannot be used directly due to uncertainties in target strength. The North Sea survey is reasonably consistent with previous years but shows a small decline, giving a total adult mortality of about 0.5 over the last 3 years, which is slightly higher than the estimates from the assessment. The North Sea herring SSB estimated from the survey rose from 2.6 million tonnes in 2001 (Table 2.3.1.5) to 2.9 million tonnes in 2002 and again to 3.0 million tonnes in 2003 and has now been seen to fall to 2.6 million. As observed last year the growth of the 2000 year class seems to be slower than for previously observed year classes. The herring are now 1.4 cm smaller, and 33g lighter than the similarly abundant 1998 year class at the same age (3-rings). Last year only 43% of this year class were mature at 2-ring compared to 77% and 86% for 1998 and 1999 year classes. This year at 3-ring only 65% are mature compared to 97% and 93% for 1998 and 1999 year classes. If this year class had grown and matured as previous years, to 95% mature, and 177g the spawning stock biomass would have been 21% higher at 3.1 million tonnes, but if the 2003 estimate were treated in the same manner (i.e. use average growth and maturity) it would give an SSB of 3.8 million tonnes, still suggesting a decline in the last year. The survey shows again the two exceptional year classes of herring (the 1998 and 2000 year classes) in the North Sea, which is consistent with the observation of exceptionally large year classes observed in the MIK and IBTS surveys (ICES 2001/ACFM:12). The 2004 estimate of the 2000 year class suggests that it may be higher than the 1998 year class at 1.1 times at age 3-ring.

The numbers and biomass of adult autumn spawning herring can be seen in Figures 2.3.1.2, the numbers at 1, 2 and 3+ rings in Figure 2.3.1.3. The spatial distribution of mean weight at 1 and 2 ring, and fraction mature at 2 and 3 ring are given in Figure 2.3.1.4. These show a considerable spatial trend which is observed each year, with larger more mature fish found in the North and smaller less mature fish found in the south and particularly the eastern north Sea. The relative spatial distributions of adult and juvenile autumn spawning herring can be seen in Figures 2.3.1.5 and 2.3.1.6 respectively. The mean weights-at-age and the fraction mature are used in the assessment, the influence of the precision of this data were discussed in detail in section 2.10 last year.

2.3.2 Larvae surveys

In 2004/05 The Netherlands and Germany participated in six surveys and managed to cover six out of ten areas. The survey effort is comparable to previous years. The areas and time periods (including numbers of samples, vessel-days in sampling and area coverage) are given in Table 2.3.2.1 and Table 2.3.2.2. The spatial extent of the surveys is shown in Figures 2.3.2.1 - 2.3.2.6. The historical background of the larvae surveys and the methods used for abundance calculation are described in the handbook for quality control. A more detailed description is available in the manual for the international herring larvae surveys in the North Sea (ICES 2004/G:05).

Each surveys in 2004 resulted in high abundance estimates. In the Orkney/Shetlands area a large spatial extension of newly hatched larvae and high larvae aggregations were observed eastwards the Orkneys as in previous years (Figure 2.3.2.1). The overall abundance in this area varies greatly between years. In 2004 the estimates are average in recent time-series.

In the Buchan area (Figure 2.3.2.2) larval distribution was spread out compared to last year. The LAI increased substantially during the last three years.

The LAI for the Central North Sea (Figure 2.3.2.3) has reduced compared to last sampling period, but the 2003 estimate was influenced by large catches at single stations. The CNS still yields a high abundance estimate. The LAIs in the CNS continuously rise over the last seven years.

Abundance estimates from the three surveys in the Southern North Sea resulted in a high index which is almost comparable to last year. Spawning starts in the second half of December in a restricted area in VIId and then spread out into VIc during January (Figure 2.3.2.4-6). As usual, an area from the French coastline to the middle of the Channel contributed most to the abundance index in the Southern North Sea.

As a general pattern, herring seem to have recolonized the sampled spawning grounds in a broader range. An overview of the historic trends for a collection of sampling areas and periods is given in Figure 2.3.2.7.

The model for the Multiplicative Larval Abundance Index (MLAI) was fitted to abundances of larvae less than 10 mm in length (11 mm for SNS) (Table 2.3.2.3). The analysis of variance and the parameter estimates are given in Table 2.3.2.4. The updated MLAI time-series is shown in Table 2.3.2.5. The estimated trend in spawning stock biomass from this model fit is plotted in Figure 2.3.2.8 versus the SSB values obtained from the ICA runs of the Herring Assessment Working Group (ICES 2004/ACFM:18).

The result of the survey in the 1st period in the SNS is influenced by a large catch at one single station. Almost 12,000 larvae per m² were caught which contribute roughly 70% to the total catch. As a general rule, additional stations should be inserted in areas with high larval concentrations to enable average calculation. Unfortunately this wasn't done here. However, there are some routines in the MLAI calculation to make it robust against patchiness effect. Exclusion of the high catch leads to a difference less than 3% on the MLAI estimate. With respect to the general noise in survey data this impact can be neglected. Thus no data were excluded from the MLAI calculation. Both the LAI per unit as well as the MLAI from the larvae surveys in period 2004/2005 indicate that the SSB has slightly increased when compared to last years WG estimate.

2.3.3 International Bottom Trawl Survey (IBTS)

The International Bottom Trawl Survey (IBTS) started out as a young herring fish survey in 1966 with the objective of obtaining annual recruitment indices (abundance of 1-ringers in 1st quarter) for the combined North Sea herring stocks. It has been carried out every year since,

and presently the survey provides recruitment indices not only for herring, but also for round-fish species as well. Examinations of the catch of adult herring during the 1st quarter IBTS have shown that this catch also indicates abundances of 2-5+ herring. Also during IBTS 1st quarter, herring larvae are sampled during the night by small, fine-meshed nets. From 1977 to 1991 the gear was a small mid-water trawl (IKMT), but due to poor catchability of this gear, the standard gear was changed to a 2 metre ring net (MIK), used since the 1991 sampling. The total abundance of herring larvae in the survey area is used as an estimate of 0-ringer abundance of the stock. Hence, a series of herring abundance indices (0-5+ ringers) are available from the IBTS programme.

2.3.3.1 Indices of 2-5+ ringer herring abundances

Fishing gear and survey practices were standardised from 1983, and herring abundance estimates of 2-5+ ringers from 1983 onwards has shown the most consistent results in assessments of these age groups. This series is subsequently used in North Sea herring assessment. Note that the abundances in Division IIIa are not included in the 2-5+ ringer indices. Table 2.3.3.1 shows the time-series of abundance estimates of 2-5+ ringers from the 1st quarter IBTS for the period 1983-2005, when Table 2.3.3.2 contains area-disaggregated information on the IBTS indices for year 2005.

2.3.3.1 Index of 1-ringer recruitment

The 1-ringer index of recruitment is based on trawl catches in the entire survey area. Indices are available for year classes 1977 to 2003 (Table 2.3.3.3). This years estimate of the 2003 year class strength (1033) indicates a very low recruitment, among the lowest on record.

Figure 2.3.3.1 illustrates the spatial distribution of 1-ringers as estimated by the trawling in February 2003, 2004 and 2005. In 2005 the main concentrations of 1-ringers were found in the south-eastern part of the North Sea. The mean length of the 1-ringers in this area is relatively small, between 10 and 14 cm (Figure 2.3.3.2.).

The Downs herring hatch later than the other autumn spawned herring and generally appears as a smaller sized group during the 1st quarter IBTS. A recruitment index of smaller sized 1-ringers is calculated based on abundance estimates of herring <13 cm (see discussion of procedures in earlier reports (ICES CM 2000/ ACFM:12, and ICES CM 2001/ ACFM:12).

Table 2.3.3.3 includes abundance estimates of 1-ringer herring smaller than 13 cm, based on a standard retrieval of the IBTS database, i.e. the standard index is in this case calculated for herring <13 cm only. Indices for these small 1-ringers are given either for the total area or the area excluding division IIIa, and their relative proportions are also shown. In the time-series, the proportion of 1-ringers smaller than 13 cm (of total catches) is in the order of 20%, and the contribution from division IIIa to the overall abundance of <13 cm herring varies markedly during the period. (Table 2.3.3.3)

About 35% of this years group of 1-ringers is smaller than 13 cm. These are almost exclusively found in the North Sea area (Table 2.3.3.3)

2.3.3.2 The MIK index of 0-ringer recruitment

This years 0-ringer index is based on 544 depth-integrated hauls with a 2 metre ring-net (the MIK). Index values are calculated as described in the WG report of 1996 (ICES 1996/ACFM:10). The series of estimates is shown in Table 2.3.3.4, the new index value of 0-ringer abundance of the 2004 year class is estimated at 61.3.

This estimate indicates a very low recruitment, of the same size as estimated for the last two year classes, 2002 and 2003. The 0-ringers were distributed westerly and southerly in the North Sea with highest concentrations in the south-western areas. However, compared to the

preceding two year classes, which is also shown in Figure 2.3.3.3, the 0-ringers of this year class are distributed in a wider area of the North Sea. This is also apparent from Figure 2.3.3.4, which illustrates the changes in absolute and relative abundance of 0-ringers in the western part of the North Sea. The relative abundance is given as the number of 0-ringers in the area west of 2°E relative to the total number of 0-ringers in the given year class. Since the year class 1982, when the relative abundance was 25%, a general increase has been seen for the western part. In the last decade, the 0-ringer abundance in this area has dominated, during the preceding two years the relative abundance was in the order of 85%, while in 2005 the relative abundance declined to ca. 55%.

2.4 Mean weights-at-age and maturity-at-age

2.4.1 Mean weights-at-age

The mean weights-at-age of fish in the catches in 2004 (weighted by the numbers caught) are presented by ICES Division and by quarter in Table 2.2.11.

Table 2.4.1.1 shows the historic mean weights-at-age (wr) in the North Sea stock during the 3rd quarter in Divisions IV and IIIa for the period 1995 to 2004. These values were obtained from the acoustic survey. The data for 2004 are taken from Table 2.3.1.4. In this quarter most fish are approaching their peak weights just prior to spawning. The spatial distribution of mean weight for 1 and 2-ringers are given in Figure 2.3.1.4. The spatial variability of mean weight is considerable. For comparison the mean weights-in-the-catch from the last ten years are also shown in Table 2.4.1.1 (from Section 2.2.1 for the 2004 values). For 4-ringers and older the mean weights in both the catch and the acoustic survey are generally either close to the long-term mean or in the case of the acoustic survey a little lower. These estimates are typical for this time series. For 3-ring herring both the catch and the acoustic survey show mean weights that are the lowest for the last 10 years supporting the view that the exceptional 2000 year class is growing slowly. Maturity of this yearclass is also found to be lower than usual (see next section). The influence of this low mean weight on the assessment of the state of the stock is discussed in section 2.10, Quality of the assessment. The weight of two ring herring is low but not unusually so. The weight of 1-ring herring is rather variable, particularly in the catch, which this year shows a low value.

2.4.2 Maturity Ogive

The percentages of North Sea autumn-spawning herring (at age) that spawned in 2004 were estimated from the July acoustic survey (Table 2.4.2.1). The values were determined from samples of herring from the research vessel catches examined for maturity stage, and raised by the local abundance. All herring at maturity stage between 3 and 6 inclusive (using an 8-stage scale) in June or July were assumed to spawn in the autumn. The method and justification for the use of values derived from a single years data was described fully in ICES (1996/ACFM:10). The values for 2- & 3-ringers taken from the acoustic survey results (Table 2.3.1.4.) For 2-ringers the proportion mature at 70% was typical for this age group. For 3 ring herring the fraction mature was much lower than last year, and is almost the lowest in the time-series, although a very slightly lower value has been observed in 1993. This yearclass was seen to be slow growing and with low proportion mature last year at 2 ring. As last year the data were examined carefully for errors and it was concluded that the 2000 year class has developed slowly since July 2002. Fraction mature, mean weight and mean length-at-age and by year are shown in Figure 2.4.2.1. This year class, possibly the largest in recent years and the first large one competing with an already large herring stock biomass, has grown more slowly than earlier year classes. The influence on the assessment of the low fraction mature at 2-ring is discussed in Section 2.10, Quality of the assessment.

2.5 Recruitment

Information on the development in North Sea herring recruitment is available from the two IBTS indices, the 1-ringer and the 0-ringer index. Further, the ICA assessment provides estimates of the recruitment of herring in which information from the catch and from all fishery independent indices is incorporated.

2.5.1 Relationship between the MIK 0-ringer and the IBTS 1-ringer indices

The 0-ringer MIK index predicts the year class strength one year before the information is available from the IBTS 1-ringer estimates. The relationship between year class estimates from the two indices is illustrated in Figure 2.5.1 and described by the fitted linear regression. Last years prediction of a very small 2003 year class was confirmed by this year's IBTS 1-ringer index of the year class. The good correlation between the indices is also evident when comparing the respective trends in indices during the period (Figure 2.5.2).

2.5.2 Trends in recruitment from the assessment

Recruitment is estimated in the ICA-assessment, and in Figure 2.5.3 the trends in 1-ringer recruitment based on 2005 assessment is illustrated. The recruitment declined during the sixties and the seventies, followed by a marked increase in the early eighties. After the strong 1985 year class recruitment declined again until the strong year classes 1998-2001. However, the 1-ringer recruitments of the recent 2002 and 2003 year classes are very low, and the 0-ringer recruitment based on the MIK index indicates that this will be followed by another low year classes 2004. The present ICA estimates of 1-ringer recruitment are 7.2 and 7.0 no10⁹ for year classes 2002 and 2003 respectively, while the estimates for 0-ringers are 20.3, 19.6 and 22.3 no 10⁹ for year classes 2002, 2003 and 2004 respectively.

2.6 Assessment of North Sea herring

2.6.1 Data exploration and preliminary results

North Sea herring is on the AFCM observation list, but was also classed as an update assessment in 2005 by ACFM. With this in mind limited exploration was carried out into the fit of the assessment. The full choice of assessment model, catch and survey weightings and the length of separable period where not explored in detail in 2005. It is proposed to carry out a benchmark assessment for North Sea herring in 2006.

2.6.1.1 Selection of weighting of indices in the assessment of North Sea herring

The usual assessment tool for the assessment of North Sea herring is ICA. The settings were the same as last year. Acoustic, Bottom trawl (IBTS), MIK and Larvae (MLAI) surveys are available for the assessment of North Sea autumn spawning herring. The surveys and the years for which they are available are given in Table 2.6.1.1.

In 2002 the HAWG moved from arbitrary index weighting as used for the previous 6 years (1996-2001) to a more objective method. This new method was developed from the work of the ACFM study group SGEHAP (ICES CM 2001/ACFM:22) which had one of its objectives to try to rationalise the survey index weighting in the assessment. The analysis is described in the 2003 report (ICES 2003/ ACFM:17). The weighting values are given in Table 2.6.1.2. The weightings applied account for sampling error of the surveys. The WG in 2002 selected index weighting which both minimised the variability in the assessment output but also reduced the retrospective revision of management parameters (F, SSB and recruitment). However, they could not find a method that minimised the revision of all of these parameters but selected the

one that performed best for two out of three. This was done by down-weighting the influence of catch of 0wr and 1wr in the assessment (Table 2.6.1.2).

The WG in 2003 made an extensive review covering both inverse variance and structural errors, and it considered that the inverse variance method provided the better method. This process meant that the weighting of surveys and catch is fixed as the sensitivity of the assessment to these weighting values has been greatly studied in recent years. The weights express the WG view that the young herring are best estimated with MIK and IBTS surveys, the older herring are best evaluated through the acoustic survey and the SSB should be estimated through the MLAI.

2.6.1.2 Period of separable constraint

Changes in the regulations in 1996 have affected the various components of the fishery differently. Recent meetings of this WG split the separable period into two different periods: 1992-1996 and 1997 onwards. In the WG 2001 it was considered that the number of years after the change in selection was long enough to use only a single separable period of four years. During 2002-2004 a separable period of five years was used. The WG in 2002 found that year on year adaptation of the separable period did not improve the performance of the assessment model and that a fixed selection period gave more stable assessments, even with changing management. Last years WG explored a 4, 5 and 6 year separable period. No important differences in the model fit or outputs were detected. The estimation of F at reference age (4wr) was not significantly different and differences in mean F_{2-6} and SSB where found negligible. So the 5 year separable period was maintained in the current assessment.

2.6.1.3 Model fit and residuals

The influence of the catch and the surveys was explored on the estimation of reference F and the model fit. ICA was run using all catch and survey data with the same procedure as last year (SPALY). The patterns in catch and survey residuals (Figure 2.6.1.1, upper panels) are similar to the assessments in 2003 and 2004 but greater in magnitude. In the assessments in 2003 and 2004, positive residuals in the catch of 2+wr fish against negative residuals in the acoustic survey and IBTS were detected. Using the same procedure as last year, the catch residuals in this year's assessment showed positive residuals for older ages in recent years, while at 2wr in the terminal year there is a large negative residual. Different trends in the residual patterns between catch and surveys indicate conflicting signals in the information.

To explore the contribution of the catch and the survey data to the specific patterns in the residuals, runs with modification to the data were explored:

- Setting the weights for the catch in the separable period to 10% of the original values for the separable period to explore the influence of the catch data on the model.
- ii. Setting the weights for the catch of 1wr and 2wr in 2004 at 0.01 to explore the influence of the large negative residual for 2wr in the terminal year
- iii. Using the acoustic survey as the only tuning fleet,
- iv. Using the IBTS as the only tuning fleet,
- v. Using the MIK survey as the only tuning fleet,
- vi. Using the MLAI as the only tuning fleet to explore the influence of the survey data on the model

Setting the weights for the catch in the separable period to 10% of the original values reduces the negative residuals in the survey data in recent years slightly (Figure 2.6.1.1, middle panels). Setting the weights for the catch of 1wr and 2wr in 2004 at 0.01 does hardly change the

patterns in the group of negative residuals in the survey data in recent years (Figure 2.6.1.1, lower panels).

Using each individual survey as the only tuning fleet did not resolve the pattern of negative survey residuals in recent years for the acoustic and the IBTS survey (Figure 2.6.1.2). The MIK and MLAI survey showed random distributions in the residuals with no apparent trend.

Depending on the data source explored, the reference F (4wr) varied between 0.20 and 0.40 (Figure 2.6.1.3a). The runs with down weighted catch (i and ii) and using only the IBTS as tuning fleet gave similar perceptions of fishing mortality on the reference age (4wr) of the separable model with estimates within the 90% confidence intervals of the run with last years settings. The acoustic survey gave slightly higher estimates of F, while the MIK and the MLAI gave slightly lower estimates. The MIK and the MLAI gave higher estimated of SSB associated with the lower reference F (Figure 2.6.1.3b). The MIK is not expected to have great power, since it is a recruitment index with information on only the 0wr.

2.6.1.4 Exploring other assessment models

The performance of ICA is explored against XSA and SURBA (ICES CM2003/D:03; Needle 2004), which is a survey-only based assessment model. ICA has been used for the assessment of North Sea herring during the last decade. Concern at WGMG was raised about the instability in the selection patterns at older ages impacting on the earlier part of the time-series (ICES CM2003/D:03). The WG in 2003 and 2004 explored the performance of ICA against another regularly used assessment model, XSA. The approach used was to choose XSA settings that reflect as many of the assumptions of the ICA model of North Sea herring.

The model settings for XSA in this years assessment are given in Table 2.6.1.3 and the summary of the results in Table 2.6.1.4. The XSA assessment is consistent with the ICA assessment (Figure 2.6.1.4) for the recruitment and F_{2-6} and SSB in historic period. Only during the last 3 years does XSA show higher estimates of mean F_{2-6} and lower estimates of SSB. Higher estimate of F and lower estimate of SSB in the terminal year by XSA might be influenced by the exclusion of the MLAI in the XSA (which cannot use biomass indices) and the effect of the weak shrinkage during a period of declining F, maybe responsible for part of the increase.

A new version of SURBA that could assess North Sea herring was developed immediately prior to the HAWG in 2005. This version could combine multiple surveys, with weighting factors and incorporated the use of a biomass tuning fleet. Its use should be viewed as exploratory and its results as preliminary as no major testing of the model or sensitivity analysis of the model settings has taken place as yet. The SURBA run had a higher mean F_{2-6} and lower SSB in the terminal year than ICA and XSA, and showed more between year variability in F in recent years than the other models.

2.6.1.5 Conclusions of exploration of the assessment

The formulation of the assessment was recently supported by an external and independent review of the North Sea herring assessment carried out for the North Sea Commission Fisheries Partnership, where the consistency, precision and quality of the assessment were judged as credible and fully acceptable as a tool for management advice. However patterns in the residuals seen in previous years and current assessment indicate that catch and survey indices show different signals. Closer investigation of the model suggested a slight underestimation of F and an overestimation of SSB in current assessment (see section 2.10), and this should be monitored closely. Therefore WG strongly suggests a benchmark assessment of North Sea herring next year. Exploratory runs of ICA and XSA however showed similar trends in the development of mean F₂₋₆, SSB and recruitment and are within the precision levels of the ICA model. As exploration provides no simple solution to the apparent conflicts between catch and survey

data, it was concluded that this years assessment method is maintained as last year, with comparable settings, tuning indices and weightings.

2.6.2 The stock assessment

2.6.2.1 The model used

The assessment of the stock was carried out by fitting the integrated catch-at-age model (ICA) including a separable constraint over a five-year period as explained above (Patterson, 1998, Needle 2000). The input data are shown in Table 2.6.2.1.

2.6.2.2 Results

The ICA output is presented in Tables 2.6.2.2 and 2.6.2.3, with model fit and parameter estimates in Table 2.6.2.4 and Figures 2.6.2.1 - 2.6.2.19. Uncertainty analysis of the final assessment is presented in Figure 2.6.2.20, although this only reflects the uncertainty in fitting the model and does not include uncertainty in the model specification. Estimates in 2004 of mean F_{2-6} vary in a similar way to last year, between 0.21 and 0.31 (25 and 75 percentile respectively), and for SSB between 1.73 and 2.14 million tonnes (Figure 2.6.2.20). There appears to be a relatively good agreement between the point estimates of the final assessment and the median values of the ICA bootstrap realisations. The estimation of mean F_{2-6} varies less than the SSB (Figure 2.6.2.21). Long-term trends in yield, fishing mortality, spawning stock biomass and recruitment are given in Figure 2.6.2.22.

The spawning stock at spawning time in 2004 is estimated at approximately 1.89 million tonnes. The abundance of 0wr fish in 2005 (2004 year class) is low for the third consecutive year. A low recruitment was also observed in the two previous years for the 2002 and 2003 year classes. The strong 1998 and 2000 year classes are still evident in the population, with the 2000 year class at 3wr in 2004 being the highest since 1964 and the 1998 year class at 5wr being the highest since 1962. Mean fishing mortality on 2-6wr herring in 2004 is estimated at around 0.25, and on 0-1wr herring at 0.05. The value of F for 2003 in this years assessment is in close agreement with last year's assessment, which was 0.24.

2.7 Short term projection by fleets.

2.7.1 Method

The program used (MFSP) was developed three years ago in the HAWG. The version used this year was the same as at last years meeting (Skagen 2003). The standard tool that currently is available for short term predictions (the MFDP program) has some limitations with regard to management options that can be covered. In particular, when varying the fishing mortality for one fleet, the fishing mortalities for the other fleets are assumed constant at status quo F. For the North Sea herring, managers have agreed to constrain the total outtake at levels of fishing mortalities for ages 0-1 and 2-6, and need options to show the trade-off between fleets within those limits. The MFSP program was developed to cover these needs.

2.7.2 Input data

Fleet Definitions

The current fleet definitions are:

North Sea

Fleet A: Directed herring fisheries with purse seiners and trawlers. By-catches in industrial fisheries by Norway are included.

Fleet B: Herring taken as by-catch under EU regulations.

Division IIIa

Fleet C: Directed herring fisheries with purse seiners and trawlers

Fleet D: By-catches of herring caught in the small-mesh fisheries

The fleet definitions are the same as last year.

Input Data for Short Term Projections

All the input data for the short term projections are shown in Table 2.7.1, which is the input file for the predictions.

Stock Numbers: For the start of 2005 the total stock number was taken from ICA (ica.n – file)

For 2006 and 2007, the recruitment was set to 49 960 million which is the geometric mean of the recruitments of the year classes 1981 - 2001.

Fishing Mortalities: Selection by fleet at age was calculated by splitting the total fishing mortality in 2004 for each age proportional to the catches by fleets at that age. These fishing mortalities were used for all years in the prediction.

Maturity at age: For all the year classes except the 2000 year class, the average maturity at age for 2001 to 2004, calculated without the 2000 year class, was used (Table 2.6.2.2). For the 2000 year class, which so far has matured more slowly than usual, the maturity was predicted by fitting a logistic function to the maturities at age observed so far. That gave a fraction mature of 0.91 as 4-ringers in 2005 and 0.98 as 5-ringers in 2006. For 2007, this year class was assumed to be fully mature.

Mean Weights at age in the stock: A similar procedure as for maturities was followed for mean weights at age in the stock. Again a 4 year average of the annual weights, excluding the 2000 year class was used for all year classes except the 2000 year class. The weights at age for the 2000 year class were obtained by fitting a von Bertalanffy function. The weights used for this purpose were the raw annual weights, while smoothed weights are used in the assessment.

Mean weights in the catch by fleet: The mean weights by fleet for the years 2002 - 2004, excluding the 2000 year class was used for all year classes except the 2000 year class. For the 2000 year class, the procedure outlined for weights in the stock was followed, assuming von Bertalanffy growth. Separate values for t_0 were estimated for each fleet. The W_{inf} and k were estimated assuming they were equal for all fleets.

Natural Mortality: Unchanged from last year, equal to those assumed in the assessment.

Proportion of M and F before spawning: Unchanged from last year at 0.67.

2.7.3 Prediction for 2005 and management option tables for 2006

Assumptions and Predictions for 2005

In 2004, the TAC for the A-fleet was overfished by approximately 15%, while the B- and C-fleets caught less than half their TAC. Catches in 2005 may be predicted with some confidence. The retrospective error has been low in recent years. It therefore seems most reasonable to use assumed catches to account for the removal in 2005. It is assumed that the TAC of 535 000 tonnes of the A-fleet will be taken, and that the bycatch by the B-fleet will increase somewhat in 2005, because it is expected to target sprat to a larger extent than in recent years due to shortage of sandeel, and closure of the fishery for Norway pout.

The alternative option assuming $F_{status\ quo}$ is also presented. The partial fishing mortalities at $F_{status\ quo}$ appear in tables 2.7.1. It should be noted, however, that $F_{status\ quo}$ gives far lower catch by the A-fleet than the agreed TAC, and also lower catch by the B-fleet than can be expected.

Management Option Tables for 2006

The EU-Norway agreement on management of North Sea herring was updated in 2004. The revised rule specifies fishing mortalities for juveniles (F ₀₋₁) and for adults (F ₂₋₆) not to be exceeded, at 0.12 and 0.25 respectively, for the situation where the SSB is above 1.3 million tonnes. In addition, it now has a rule specifying reduced fishing mortalities when the SSB is below 1.3 million tonnes. Moreover, the current agreement has a constraint on year-to-year change of 15% in TAC, but allows for a stronger reduction in TAC if necessary.

With four fleets there are innumerable combinations of fleetwise fishing mortalities and catches that satisfy the agreed rules. The predictions presented are in accordance with the agreed arrangement.

Since the North Sea autumn spawning (NSAS) stock was rebuilt, the advise has been that the primary limiting factor for the fishery in IIIa should be the concern for the Western Baltic spring spawning (WBSS) stock. Using that as a guideline, and in order to reduce the number of possible options, a range of fixed catches were assumed for the fleets C and D derived from the likely recommended outtake of WBSS. The procedure for obtaining these catch limitations are described in detail in Section 3.10. In brief, the historical fractional distribution of the WBSS catches on IIIa and the other areas is used to translate the total recommended TAC for WBSS into outtake of WBSS in IIIa. Then, the mix of WBSS and NSAS in the IIIa catches is used to derive the outtake of NSAS in IIIa. Assuming a total catch of WBSS of 95 000 tonnes (see Section 3.7) led to a catch of 16 600 tonnes of NSAS herring for the C-fleet and 11100 tonnes of NSAS herring for the D-fleet by this procedure.

It has become increasingly clear that in previous years, large parts of the catches reported for IIIa were actually taken in the North Sea. For 2004, Norway was allowed to transfer all of its quota in IIIa to IV, while the EC could transfer 50% of its quota. For 2005, Norway could again transfer its quota in IIIa to IV, while the EC could not. Furthermore, the last 3 year classes of NSAS have been weak, implying relatively small amounts of NSAS in IIIa. Therefore, it seems likely that the current fleet behaviour, with relatively small catches of NSAS in IIIa will be continued in the coming years.

In each set of predictions, a range of fixed catches were assumed for fleets C and D (8300, 12450 and 16600t for fleet C and 5500, 7750 and 11100t for fleet D). For each combination of these, the catches by the fleets A and B were adjusted to give an F_{0-1} at either 0.05, which is close to the F status quo, or the agreed value of 0.12, and to an F_{2-6} at 0.25. In addition, because these predictions lead to a reduction of catches by the A-fleet of slightly more than 15% compared to the 2005 TAC, a similar set of predictions were done with a fixed catch by the A-fleet at 85% of the 2005 TAC, i.e. 455 000 tonnes.

The text tables below is an overview of the options.

Predictions with F_{status quo} for 2005

Status quo F-values by fleet:

A: F2-6 = 0.240, B: F0-1 = 0.036, C: F0-1 = 0.003, D: F0-1 = 0.010

ASSUMP- TION FOR 2005	F ₀₋₁ 2006	F ₂₋₆ 2006	FLEET A	FLEET B	CATCH FLEET C 2006	CATCH FLEET D 2006
F status quo	0.05	0.25	Derived F and catch	Derived F and catch	8300 – 16 600 t	5 500 – 11 100 t
F status quo	0.12	0.25	Derived F and catch	Derived F and catch	8300 – 16 600 t	5 500 – 11 100 t
F status quo	Approx 0.05	Derived	Assumed catch 455 000 t	Derived F and catch	8300 – 16 600 t	5 500 – 11 100 t

All predictions are for North Sea autumn spawning herring only.

The results are presented in Table 2.7.2. In addition, runs were made screening over narrow intervals of catch options for all fleets, as requested in the Memorandum of Understanding between ICES and its client commissions. The results file is too extensive to be included in the report, but is available on the WG directory.

2.7.4 Comments on the short-term projections

Making fleetwise predictions for 4 fleets that are more or less independent remains problematic, in particular when it comes to presenting results in a way that allows managers to overview the range of possible trade-offs between fleets.

It is also worth noticing that the realised F_{2-6} in the past have exceeded that intended when setting the TACs for many years. If managers wish to avoid exceeding the agreed limits, options with lower F-values may be preferable.

All scenarios presented indicate a decrease in spawning biomass and in yield. This is mainly caused by the weak 2002, 2003 and 2004 year classes taking over from the strong 1998 and

2000 year classes. The catches by the A fleet are estimated close to the lower bound implicit in the constraint on TAC reduction agreed by EU and Norway at $F_{2-6} = 0.25$, while the catches by the B, C and D fleets is a trade-off between these fleets, the sum of which will be approximately 70 - 80~000 tonnes with an $F_{0-1} = 0.12$.

The predictions presented here account for the delayed maturation of the large 2000 year class. To what extent the increased stock size will lead to slower growth and maturation in the future remains to be seen. There are some indications that this was the case when the stock was large prior to 1960 (ICES 1998/ACFM:14), but there are no indications of reduced growth of the 2001 and 2002 year classes.

The estimated impact of the juvenile fishery depends on the assumed value for natural mortality. It has not been investigated to what extent changes in natural mortality would affect the current advise, or if indeed such changes are taking place.

2.8 Medium term predictions and HCR simulations

Medium term predictions were performed to explore the robustness of the newly agreed harvest control rule (HCR), in light of the present situation where several recent year classes have been well below average. HCRs for North Sea herring were extensively evaluated in June 2004 (Anon 2004. EU Norway ad hoc Scientific Working Group on Multi-annual Management Plans for Stocks shared by EU and Norway). The initial stock numbers are taken from the most recent assessments. Because all year classes after the 2000 year class now appear to be weak, the initial data reflect this exceptional situation to a larger extent than in the predictions made in June (Figure 2.8.1).

The software used was STPR3, the same as used at the evaluation of HCRs for North Sea herring in June 2004. This is a program for performing 10 years stochastic simulations of the stock and fishery, applying some HCRs. A description can be found i.a. the SGMAS report (ICES 2005, ICES CM 2005 /ACFM:09).

2.8.1 Input data:

The program was run with 2 fleets, Fleet 1 corresponds to the A-fleet and Fleet 2 corresponds to fleets B, C and D combined.

Stock numbers in the initial year 2005 and their variance-covariance matrix were taken from the current ICA output (ica.n and ica.vc)

The stock-recruitment function was the same as used in June 2004. It assumed recruitment of 49342 millions independent of SSB at SSB larger than 547 thousand tonnes, and a linear reduction of the recruitment at lower SSB. The recruitment was drawn from a log-normal distribution with $\sigma=0.572$. A comparison of the ensuing model recruitments with historical recruitments (except those generated by a SSB below 547 000 tonnes) is given in Figure 2.8.2.

For weights and maturities historical data were used, by drawing years randomly and using data from that year.

Fleetwise selection at age were equal to those used in the short term prediction (Table 2.7.1)

For the intermediate year, fleetwise fishing mortalities at Fstatus quo (Fleet 1: 0.24, Fleet 2: 0.049) were assumed.

2.8.2 Harvest rule:

The harvest rule agreed by Norway and EU from 2004 was simulated:

```
At SSB > 1.3 million tonnes: F0-1 = 0.12 and F2-6 = 0.25
```

At SSB < 1.3 million tonnes and SSB > 800 000 tonnes:

```
F0-1 = 0.12 - (0.08*(1300\ 000 - SSB)/500\ 000)
```

$$F2-6 = 0.25 - (0.15*(1300\ 000 - SSB)/500\ 000)$$

For SSB $< 800\ 000\ tonnes$: F0-1 = 0.04 and F2-6 = 0.10

In addition, there is a constraint of 15% on the year-to-year change in TAC. A larger reduction can be implemented, but was not simulated, as the criteria for deviating from the 15% rule are not precisely known.

The agreement does not state the year which the SSB refers to. The SSB considered by STPR3 is the SSB in the quota year.

2.8.3 Simulation options:

Three HCR scenarios were studied:

- 1. The rule as agreed by Norway and the EU (Figure 2.8.a)
- 2. The rule as agreed by Norway and the EU, but with a F0-1 of 0.05 instead of 0.12 (Figure 2.8.b)
- 3. The rule as agreed by Norway and the EU but without the lower bound on year to year change in TAC (Figure 2.8.c)

Simulations were made where the HCR was applied to precise estimates of the stock, and were implemented precisely as decided. Furthermore, deviations were simulated by using random multiplies as follows:

- i. No deviation, but CV = 0.1 on both assessment and implementation error.
- ii. Assessment error: mean 1.1, CV: 0.1; Implementation error: mean 1.1, CV: 0.1
- iii. Assessment error: mean 1.2, CV: 0.1; Implementation error: mean 1.2, CV: 0.1

The results are shown in Figures 2.8.3 a-c as probability that the 'true' SSB (i.e. in the operating model) is below 800 000 tonnes and 1300 000 tonnes. Furthermore, percentiles by year are shown for SSB and realised fishing mortalities for each of the fleets.

2.8.4 Results

The results are shown in Figures 2.8.3 a-c. In all cases, the SSB goes down at least until 2008, which is to be expected when 3 poor year classes enter the stock in succession. In the ideal world, where both assessment and implementation are unbiased, the stock seems to recover, and the risk for the SSB falling below 1.3 million tonnes is relatively small. However, even moderate bias in assessment or implementation, leading to a larger removal than corresponding to the intended fishing mortality, carries a considerable risk of bringing the stock out of control, with an escalating fishing mortality and a deteriorating spawning stock. Not only is there a risk of bringing the stock below reference levels, the agreed rule does not seem to be sufficient to rebuild the stock if it cannot be strictly adhered to.

Having a lower fishing mortality on the juveniles, as it has been in the recent years, will reduce the risk of falling below reference levels, and enable rebuilding, even with a moderate bias in assessment and implementation. If the bias is more severe (20% on both assessment

and implementation), this modification of the harvest rule cannot prevent the stock from getting out of control.

Applying a larger reduction in TAC than 15% whenever needed, as the agreed rule allows for, is helpful in the sense that it prevents the fishing mortality from coming out of control.

The present situation, with 3 poor year classes in succession, is exceptional in the sense that it is unlikely to occur when drawing recruitments randomly in a simulation routine. The performance of the present harvest rule is a best marginal in this situation, since it may easily break down if assessment and/or implementation are sufficiently biased. As noted in Section 2.10, the present assessment may possibly be an overestimate, and the TACs in the consumption fishery have regularly been overfished.

Allowance for efficient reduction of the TACs at an early stage increases the robustness of the regime. In particular, too great a constraint on reduction of the outtake when the stock is declining may lead into a vicious circle, which is clearly demonstrated in some of the examples here. The simulations also show the beneficial effect of reducing the fishing mortality on juveniles. The effect of a lower fishing mortality on adults was not explored in this study. An additional problem is that the effect of the juvenile fishery is dependent on the assumed natural mortality, which is high. Exploring the validity of these high natural mortalities, which are derived from the MSVPA, and the impact of the assumed natural mortality on the performance of the harvest rule ought to be explored, but was outside reach of this WG.

2.9 Precautionary reference points

In 2003, SGPRP (ICES 2003 ACFM:04) suggested to reduce B_{lim} from the current 800 000 tonnes to about 560 000 tonnes, based on the results of the segmented regression analysis of the stock and recruitment data. Fitting an "Ockham Razor" stock-recruit function with nonlinear minimisation of the SSQ of log residuals (section 2.8) suggests a break point at 537 000 tonnes. Although it is apparent that the recruitment historically has been at about the same level when the SSB was somewhat below 800 000 tonnes as above, HAWG decided not to propose any revision of the reference points at present for the following reasons:

- There is some doubt as to the validity of the calculation procedure used by the SGPRP
- HAWG would prefer to consider all reference points together, rather than revising just B_{lim}.

Moreover, the harvest control rule in place for this stock worked well in the recent past, and apart from B_{lim} , the current reference points are derived from this HCR. The target F in the HCR was adopted by ACFM as F_{pa} , while the trigger point at which F should be reduced below the target is adopted as B_{pa} . Future revisions of the reference points should not trigger alterations in this HCR (see section 2.8).

2.10 Quality of the Assessment

2.10.1 Sensitivity of the assessment to sampling variability in the input data

The influence of sampling variability in the input data on the output of the assessment has been explored through the bootstrap analysis, documented in SGEHAP report (ICES 2003). This was reported in detail in the 2003 Working Group report. All the analyses carried out by this method are conditional on the total catch in tonnes, the Working Group choice of fixed natural mortality and the choice of assessment method ICA (Patterson 1998, and Needle 2000) with predefined inverse variance weighting of the data. The model formulation and index weighting are described in Section 2.6.1. The study showed that estimates of terminal SSB and $F_{2.6}$ are the most sensitive to the precision of the Acoustic survey, which is the most precise survey for adults. The IBTS, MIK and MLAI surveys form a second group with precision in-

fluencing the results to a lesser extent. The variability due to sampling for estimates of catch in numbers at age, the weights-at-age in the stock and the fraction mature form a third group of factors, and these have the least influence. SSB does vary a little due to sampling errors in mean weights and maturity but F is almost independent of these parameters. The results show that the estimates of TAC were almost equal dependent on Acoustic survey IBTS and MIK, with some influence from catch at age and MLAI but almost no influence from maturity or mean weights in the stock.

2.10.2 Weighing of indices and catch in the assessment

The tuning index weighting in the ICA assessment was considered in detail (Simmonds, 2003) and the resulting weights are given in Table 2.6.1.2 The relatively high weights on catch (3.17 & 2.65 for 2wr and 3wr herring respectively) do not make the assessment overly dependent on measurement variability in the catch. The effect of down weighting the catch can be seen in Figure 2.6.1.3, confirming that these weights have little influence on the estimate of terminal F or SSB, increased weights do provide some stability rather than determining the terminal values.

The adaptive weighting from the XSA assessment (presented in section 2.6) are given in Table 2.10.1. The weighting of indices in the current assessment can be compared to weighting in the XSA assessment. XSA weighting is adaptive changing weighting within the model. The weighting values are taken directly from the model output tables. It is difficult to compare these values directly. But the general structure of weighting among the surveys is similar. The highest weights go to the MIK for the 2003 yearclass (0wr). Weighting is shared almost equally between IBTS and the acoustic survey for 2002 yearclass (1wr) with increasing weight to the acoustic survey and declining weight to the IBTS as the year classes get older.

2.10.3 Sensitivity to measured maturity

The fraction of the 2000 yearclass that spawned for the first time in 2003, estimated from the 2003 and 2004 acoustic survey, was 43% of the yearclass in 2003 and 65% in 2004. This is close to the lowest fraction mature in the recent history of the stock (1984-2002) and compares with values at age 2wr of 77% and 86% in 2001 and 2002 and 97% and 93% at age 3wr in 2002 and 2003 respectively. The source of the data is discussed in section 2.4.2. The weight at age for the 2000 yearclass has also been well below average since 2003 (see table 2.4.1). The data support the view that there is a significant decrease in fraction mature, which is probably due to slow growth of this very large yearclass. The implications for the assessment is that the SSB is estimated as lower than would otherwise be the case. The effect was evaluated by comparing of growth and maturity data from the acoustic survey in previous years. This shows that had all the 2-ring herring both grown and matured at a rate equal to the average of the previous 3 years (95% mature) this would have resulted in an increase in SSB of 21% or 2.29 Mt.

2.10.4 Use of tuning indices in the 2005 assessment

In this year's surveys, the IBTS and MLAI surveys display a substantial upward trend in SSB, in contrast to the Acoustic index that shows a small decline. In single fleet tuning of the ICA assessment these translate into Acoustic Index: 2% decline, IBTS: 9% increase and MLAI: 14% increase in SSB from 2003 to 2004. The MIK can also be used to tune the assessment but as this only provides a recruitment index the results are not that informative as a tuning index for the older parts of the population. ICA provides a variance/covariance method to bootstrap parameters estimated in the assessment. The scatter plot from 100 bootstrap estimates (Figure 2.10.3) are shown together with the locations of the individual assessments using indices on their own. The spread of terminal F and SSB is consistent among indices and with the combined assessment. The Acoustic survey suggests a lower SSB and higher F, the MLAI the

highest SSB and lowest F. From it can be seen that although there is a difference in perception of SSB when using each index separately they individually lie within the spread of the bootstrap evaluation of precision indicating that they individually lie within the confidence intervals for the assessment.

2.10.5 Comparison with the 2004 assessment and projection

The 2005 assessment is in good agreement with last years assessment see table below.

ASSESSMENT YEAR	SSB IN 2003	F2-6 IN 2003	SSB IN 2004	F IN 2004
2004	1.74 M t	0.24	Projected 2.01 Mt	Projected 0.25
2003	1.73 M t	0.25	Assessed 1.89 Mt	Assessed 0.25

These values are in relatively good agreement, F is consistent and SSB projected for 2004 was only a 6% overestimate of the current assessment. Last year's projection accounted for the reduced fraction mature of the 2000 year class so the projected and assessed SSB should be comparable within the context of the precision of the assessment..

2.10.6 Uncertainty in the 2005 assessment

The current estimate of SSB is dominated by the highly abundant 3-ringers in 2004. Figure 2.10.1 provides a scatter plot of F against SSB for this assessment, the spread of SSB is slightly wider than in 2004 suggesting a less precise assessment than last year.

As noted in Section 2.6.1 there was some clustering of negative residuals in both the acoustic and IBTS survey data. Figure 2.10.2 shows the residuals averaged over ages and over 3 years, to highlight the trends. The acoustic survey residuals at older ages have a clear downwards trend since about 1996, indicating that increasingly less fish is found in the survey, compared to that indicated by the ICA model. There is no similar trend at the youngest ages. A similar analysis of trends in the IBTS survey are less clear because the survey is noisy, and this survey does not cover the older ages well but over a longer time period there is a shift in exploitation between survey and assessment. The same information is only available for 5 years for catch, so trends are not that meaningful.

The mortality signal as inferred from the log survey index ratios (Figure 2.10.3) show no trends in the surveys. The log catch ratio shows a downward trend for the older ages. If it can be assumed that survey catchability is constant over time, the surveys indicate a rather stable mortality. The declining trend in log catch ratios would then most likely be caused by a relative increase in exploitation a older age, i.e. a twisting of the selection at age. It is a twisted selection at age that thus emerges as the most plausible cause of the discrepancy between trends in catch and survey residuals. The impact of such twisting on the assessment is not straightforward, as it is influenced both by the relative strengths of the conflicting signals, and of secondary effects when attempting to improve the fit. The fit to the relatively high catches at old age in recent years could be improved by

- 1. raising those cohorts in the modelled population.
- 2. increasing the fishing mortality in 2004 or
- 3. increasing the selection at old age.

Increasing these cohorts is contradicted by the survey data. Increasing the fishing mortality would give a better fit to the survey data, but is contradicted by the low catches at young age. The selection at age is a compromise between the requirements in the beginning and the end of the separable period.

To elucidate the effect of the twisting of selection at age, some alternative assessments were made for comparison and have already been presented in the data exploration. An XSA which does not fit a fixed selection pattern gave a less marked rise in SSB in recent years and a

higher F. A less marked rise in SSB was also seen in a run with SURBA, which uses only the survey data. Though SURBA is rather noisy, especially in the last years and XSA might be expected to lift the F through the action of shrinkage. Both these indicate that within an ICA assessment the effect of a twisting in selection with the low catches at young age in 2004 lead to a low estimate of terminal F and a high estimate of the recent SSB. Finally, runs of ICA with down-weighting of the all catches and just with ages 1-2 in 2004 also indicated that these data had some effect on the SSB estimate in recent years (Figure 2.6.1.3).

The effect of down-weighting on young ages in the catch on the final estimate of terminal F, and on the estimate of stock abundance, in the recent years, and the finding that most alternative procedures give lower estimates for the SSB in the final year, suggest that the present update assessment may have a higher probability of overestimating the stock and underestimating the fishing mortality.

The formulation of the assessment was recently supported by an external and independent review of the North Sea herring assessment carried out for the North Sea Commission Fisheries Partnership, where the consistency, precision and quality of the assessment were judged as credible and fully acceptable as a tool for management advice. All these changes discussed here are well within the precision of the assessment, and there is no way to determine conclusively whether the residuals are caused by year effects in the surveys, or changes in fishing pattern, though the latter is thought more probable as the TAC has recently increased giving opportunity for changes in fishing behaviour.

Experience from earlier years (2003 HAWG report) suggest that tinkering with the selection pattern and down-weighting individual observations in catch while looking plausible in an assessment year were found to be less stable than continuing with a fixed separable period. Nevertheless, further exploration of what would be an appropriate method for assessing the stock should be undertaken, but is outside the scope of an update assessment, requiring preparation before a HAWG, preferably within the framework of a benchmark assessment in 2006 and HAWG recommend that this should be required.

However, in this context it is important to remember that the conclusions that; the stock has increased markedly in recent years, that the fishing mortality is at a moderate level, and that recruitment has been low since 2001, are robust across models and assumptions.

2.10.7 Comparison with earlier assessments

An historic retrospective of assessments by sequential working groups is presented in Figure 2.10.4. Values for retrospective bias and standard error (Jónsson and Hjörleifsson 2000) are presented in the figures. The magnitude of the revision seems to be different in different periods, it is less in the last four years (2000-2003) than for the years 1998 and 1999, and then improves again in 1996 and 1997. It is thought this period of the assessment has been made more difficult due to the difficulties in modelling the change in the fishery from 1996 and 1997, following the changes in management At the time the model was adapted annually to cope with this but retrospectives from today indicate that the current fixed assessment would have been better than the attempts to model the changes. This perception that tinkering did not help is one reason for suggesting that it is better to follow the current assessment model for one more year and to review the whole procedure as a bench mark assessment in 2006.

Cohort retrospectives are shown in Figure 2.10.5. The 2000 year class (93,000 million) is thought to be third highest in the history of the stock since 1960, at 97% above geometric mean recruitment (1983-2002), and larger than the 1998 year class (71,000 million) which has provided the recent large rise in the SSB. Both these cohorts have been estimated with little change from year to year. Estimates of incoming year classes (2001-2003) are still variable in particular the 2001 year class (3-ring herring in 2005) which has been estimated by the MIK at 0-ring, IBTS at 3,2&1 and Acoustic index at 2&1-ring is particularly variable; these estimates

are not all in good agreement but do confirm the yearclass is small. The current estimate of 42,000 million is 12% below geometric mean and reduced from last. The 2002 year class (2-ring in 2005) is estimated by the MIK and the IBTS and acoustic surveys which are in relatively good agreement and is thought to be low at about 42% of geometric mean recruitment (this was estimated at 40% and 43% of geometric mean recruitment in 2003 and 2004 respectively). The 2003 yearclass is estimated by MIKand IBTS and is even lower at 40% of geometric mean recruitment. The 2004 year class (not shown in Figure 2.10.5) is only estimated by the MIK and is also a low yearclass at 47% of geometric mean.

The retrospective selection patterns show a marked change in 2001 (Figure 2.6.2.24), this is probably due to separable period moving back through time of the change in the catching behaviour and management of the fishery in 1996. The fitted selection in 2004 suggests lower exploitation of juveniles than in earlier periods.

2.10.8 Predictions

The short-term prediction method was substantially modified in 2002. Following the review by SGEHAP (ICES 2001/ACFM:22), which recommended that a simple multi-fleet method would be preferable, the complex split-factor method used for a number of years prior to 2002 has not been used since. The multi-fleet, multi-option, deterministic short-term prediction programme (MFSP) was accepted by ACFM and was developed further last year. It is intended to continue to use this programme in the future. Last year's short-term prediction suggested that the North Sea autumn-spawning herring stock SSB in 2005 would be around 2.01 Mt. This compares reasonably well with this year's estimate of the 2005 SSB which is 1.89 Mt, a reduction of 6%. Both projection and estimate take low maturation into account. This demonstrates that the current prediction procedure for stock numbers is working reasonably well. The Working Group has included prediction of low maturation into projections for 2006 and expects to monitor growth and maturation of North Sea herring carefully in the future and when deemed necessary will include these changes in predictions in the future.

Simmonds, E. J. (2003). "Weighting of acoustic- and trawl-survey indices for the assessment of North Sea herring." <u>ICES J. Mar. Sci.</u> **60**: 463-471.

2.11 Herring in Division IVc and VIId (Downs Herring)

Over many years the working group has attempted to assess the contribution of winter spawning Downs herring to the overall population of North Sea herring. There is a separate TAC for herring in Divisions IVc and VIId as part of the total North Sea TAC. The TAC for IVc and VIId in 2005 was increased from 66,098 tonnes to 74,293 tonnes, the highest TAC in the last 20 years and since the recovery of the stock (Table 2.11.1, Figure 2.11.1). This was a 11% increase on the TAC from 2004 and represent 1.75 times of the long term mean TAC for Downs, and 14% of the total TAC for North Sea Autumn spawning herring.

ACFM has been concerned that the TAC should not be raised faster than the whole TAC for North Sea herring, and suggested in 2004 that the TAC for IVc and VIId should be approximately 11% of the total TAC for North Sea Autumn spawning herring. ACFM also noted with concern the wide scale and historic tendency to over fish the TAC in IVc and VIId.

The strong 2000 year class dominated recent catches in IVc and VIId, making up 55% and 69% of the catch by number in 2003 and 2004 respectively. As has been noted previously these fish are smaller than average for their age and also have a lower proportion mature than average. In 2004 the amount of overfishing appears to have reduced to 3% of the TAC, which is well within the error of catch-estimation.

Historically the Downs herring has been thought as highly sensitive to overexploitation (Burd, 1985; Cushing 1968; 1992). It is less fecund and expresses different growth dynamics and

recruitment patterns to the more northern spawning components. Further more the targeted fishery in quarters 4 and 1, operates on aggregations of spawning herring. The Downs herring mixes with other components of North Sea herring in the summer whilst feeding. Hence, it has been impossible to determine the complete catch of the Downs herring as the catch of the summer fishery contains different components.

The proportion of the autumn and winter spawning components in North Sea herring has been traditionally monitored through the abundance of different sized fish in the IBTS. 1 wr fish from Downs spawning sites (winter) are thought to be smaller than those from the more northern, autumn spawning sites (<13 cm and >13 cm respectively). Both the total abundance of smaller 1wr fish and the proportion that is smaller have increased in recent years (Figure 2.11.2). These data suggest that 30% of the strong 2000 year class came from Downs production, and that approximately 70% of the weaker 2002 year class originates from Downs production.

Further evidence on the role of Downs herring became available in 2003 and 2004. Two projects used microstructure of the otoliths to determine spawner type. In July 2003, 17% of the fish in a sample caught to the immediate east of Shetland were winter spawners. In 2004, over 20 samples from the landings of the Dutch fleet were sampled in May to July. These samples came from the central and northern North Sea and contained both autumn and winter spawners (see WD 1). The majority of fish in the majority of samples were winter spawners (Fig. 2.11.3). When these values were raised to total Dutch catch in quarters 2 and 3, winter spawners accounted for 59% of the catch and autumn spawners for 39%. Hence the Dutch fleet which is the major exploiter of the Downs herring in December and January was also relying on Downs fish during their summer fishery in 2004. The size of these fish suggests that they were mostly from the 2000 year class, although no annual ageing of the fish was carried out.

2000 and 2002 year classes- It is apparent that the Downs component can, and did in 2004, make a sizable contribution to the total fishery on the North Sea herring stock (at least 93 k tonnes from identifiable sources). This contribution was mostly by the 2000 year class. In the future, there is a suggestion that the proportionate contribution may be larger for the 2002 yearclass (Figure 2.11.2).

2003 and 2004 year classes- It appears probable that the recruitment for the 2003 and 2004 year classes of Downs herring is poor (Figure 2.11.4), based on the MIK index for the southern North Sea, and the concordance between the estimates from the MIK survey and the IBTS 1wr estimates (<13cm). This is despite the high larval abundances for these years (but the larval estimates have high variance). Hence it is probable that the productivity of the Downs component will reduce over the next few years, as the 2000 and 2002 year classes are fished out.

The Downs herring has returned to its pre-collapse state of being a major component of the stock but is currently dominated by one year class. Hence the management of the fishery on the spawning aggregations of Downs herring should more cautious. More evidence about the dynamics and catches of Downs herring is required. Hence, HAWG recommends that the existing surveys of herring in the southern North Sea and English Channel be maintained and that the microincrement analysis of otoliths (to determine spawning type) is expanded to other fleets in the North Sea and also carried out on samples collected during the annual acoustic survey.

The IVc and VIId TAC is specific to the conservation of the spawning aggregation of Downs herring. Downs herring is caught in large numbers in other areas during the rest of the year. The TAC is the highest in 20 years and low recruitment to the component is probable in the next few years. Thus, HAWG recommends as a preliminary measure that the IVc-VIId TAC

should be reduced now to 11% of the total North Sea TAC (as recommended by ACFM) as a matter of urgency, and that research effort into the dynamics of this component be increased.

2.12 Management Considerations

Based on the most recent estimates of SSB and fishing mortality, the North Sea autumn spawning herring stock is considered to have full reproductive capacity and to be harvested sustainably. SSB in 2004 was estimated at 1.89 million t and is expected to increase to decrease to 1.82 million tonnes in 2005, which is above the \mathbf{B}_{pa} of 1.3 million t. SSB has now peaked since the rise from the low stock size in the mid-1990s, in response to reduced catches, strong recruitment and management measures that reduced exploitation both on juveniles and adults. The stock is managed according to the EU-Norway Management agreement which was updated on 26 November 2004, the relevant parts of the text are included here for reference:-

- 1. Every effort shall be made to maintain a level of Spawning Stock Biomass (SSB) greater than the 800,000 tonnes (Blim).
- 2. Where the SSB is estimated to be above 1.3 million tonnes the Parties agree to set quotas for the directed fishery and for by-catches in other fisheries, reflecting a fishing mortality rate of no more than 0.25 for 2 ringers and older and no more than 0.12 for 0-1 ringers.
- 3. Where the SSB is estimated to be below 1.3 million tonnes but above 800,000 tonnes, the Parties agree to set quotas for the direct fishery and for by-catches in other fisheries, reflecting a fishing mortality rate equal to:
- 4. 0.25 (0.15*(1,300,000-SSB)/500,000) for 2 ringers and older, and
- 5. 0.12 (0.08*(1,300,000-SSB)/500,000) for 0-1 ringers.
- 6. Where the SSB is estimated to be below 800,000 tonnes the Parties agree to set quotas for the directed fishery and for by-catches in other fisheries, reflecting a fishing mortality rate of less than 0.1 for 2 ringers and older and less than 0.04 for 0-1 ringers.
- 7. Where the rules in paragraphs 2 and 3 would lead to a TAC which deviates by more than 15% from the TAC of the preceding year the Parties shall fix a TAC that is no more than 15% greater or 15% less than the TAC of the preceding year.
- 8. Not withstanding paragraph 5 the Parties may, where considered appropriate, reduce the TAC by more than 15% compared to the TAC of the preceding year.
- 9. By-catches of herring may only be landed in ports where adequate sampling schemes to effectively monitor the landings have been set up. All catches landed shall be deducted from the respective quotas set, and the fisheries shall be stopped immediately in the event that the quotas are exhausted
- 10. The allocation of TAC for the directed fishery for herring shall be 29% to Norway and 71% to the Community. The by-catch quota for herring shall be allocated to the Community
- 11. A review of this arrangement shall take place no later than 31 December 2007.
- 12. This arrangement enters in to force on 1 January 2005.

Landings of adult herring in recent years have consistently exceeded the agreed TAC, mainly due to unallocated catches and catches misreported into and out of the North Sea (see section 2.1).

The 1998 year class and the 2000 year classes appear to be very strong in all the surveys and in the catches. They will comprise 26% and 13% of SSB in 2005 respectively. In the past large year classes have tended to have a lower maturation rate than the long-term average. These signals have not been detected for the 1998 year class as the proportion mature appears to be above average. However, the 2000 year class has been seen to exhibit a reduced growth and maturation in 2003 and 2004. As this is expected to continue in 2004, the reduction has been taken into account for the short-term projections.

The ICES advice for 2006 is based on the projected SSB in 2006 being above 1.3 million t. SSB in 2006 depends on the fisheries in 2004 and that part in 2005 that takes place before spawning. About 2/3 of the total mortality is expected to be realised before spawning each year. The increase in SSB projected for 2005 depends on the incoming 2002 year class surveys suggest that this is one of the lowest observed in the last 23 years. Generally, the surveys provide more reliable indications of year class strength than the catches of juveniles do. The 2003 yearclass is also estimated as low and initial estimates of the 2004 year class is that it is also low and only slightly above the 2002 and 2003 year classes. It is anticipated that with three small year classes in a row the stock will now decline for a number of years.

The HCR that conforms to the management agreement given above has been tested with medium term simulation and the results are given in Section 2.8. The present situation, with 3 poor year classes in succession, is exceptional. The performance of the present harvest rule is at best marginal in this situation, since it may easily break down if assessment and/or implementation are sufficiently biased. As noted in Section 2.10, the present assessment may possibly be an overestimate, and the TACs in the consumption fishery have regularly been overfished. For this situation we need a HCR that is robust to errors in the assessment and implementation error, the current one is not thought to be sufficiently robust. As the stock is set to reduce more rapidly than expected, managers should be particularly cautious and ensure that reduction in TAC are sufficient to maintain F at the agreed level of F=0.25. In this context it would be advisable for managers to explicitly include implementation failure into the TAC, such as area misreporting, if they cannot ensure compliance.

Due to the current unusual circumstances of a clearly identified sequence of three poor recruiting year-classes of North Sea herring it is particularly important that management action should address the imminent decline of this stock with sufficient determination to ensure the safety of the spawning stock in the next few years.

Discards were so far considered to be relatively unproblematic in the North Sea herring fishery (less than 5% of the total catch, based on observer sampling programs). In 2002 for the first time, onboard sampling observed substantial discards of herring in the mackerel fishery in the 3rd and 4th quarter in Div. IVa(W). The discard figure used for the assessment was 17,000 t. For 2003, discarding was estimated at 4,100 t but for 2004 the estimate had risen again to 17,000 t. These estimates come from rather limited reports from discard programmes and may not include the full extent of discarding.

This stock complex also includes Downs herring (herring in Divisions IVc and VIId), which has shown independent trends in exploitation rate and recruitment, but cannot be assessed separately. This year the Working Group concludes that the current state of the component is unknown. The WG's understanding of the component's dynamics is unlikely to improve until further examination of catch and the existing time series of surveys takes place. Both, alternative assessment methods have to be explored, and a greater knowledge the ecology of Downs herring is needed. The Downs fishery is concentrated on the spawning aggregations in a restricted area, which makes this stock component particularly vulnerable to excessive fishing pressure. The EU splits its share of the total North Sea herring TAC (Subarea IV and Division VIId) into TACs for Divisions IVa+IVb and for Divisions IVc+VIId. In response to ICES advice in May 1996, the IVc+VIId TAC was reduced by 50% in line with reductions for the whole North Sea. The TAC for Downs herring was reduced to 25 000 t and remained there until 2001. The catches for this component have significantly exceeded the sub-TACs in all years since 1989. The sub-TAC was increased in 2002 (to 42,673 t) following the advice of ICES in 2001. Subsequently the TACs for 2003 to 2005, were increased first to 59,542 t, then to 66,098 t and finally to 74,293 t against the advice of ICES. The 2004 ACFM advice was "that it should not increase faster than the TAC for the North Sea as a whole. [A] share of 11% on the total North Sea TAC (average share 1989-2002) would be an appropriate guide to distributing the harvesting among Downs herring"

The IVc and VIId TAC is specific to the conservation of the spawning aggregation of Downs herring. Downs herring is caught in large numbers in other areas during the rest of the year. The TAC is the highest in 20 years and low recruitment to the component is probable in the next few years. Thus, HAWG recommends as a preliminary measure that the IVc-VIId TAC should be reduced now to 11% of the total North Sea TAC (as recommended by ACFM) as a matter of urgency, and that research effort into the dynamics of this component be increased.

Since the North Sea autumn spawning (NSAS) stock was rebuilt, the advise has been that the primary limiting factor for the fishery in IIIa should be the concern for the Western Baltic spring spawning (WBSS) stock. This affects advices for the C and D fleets operating in IIIa. This issue is dealt with in detail in the discussion of short term predictions in Section 2.7. and Section 3.10. Following the procedure set out in section 3.10 and assuming a total catch of WBSS of 95 000 tonnes (see Section 3.7) leads to a catch of 16 600 tonnes of NSAS herring for the C-fleet and 11 100 tonnes of NSAS herring for the D-fleet. For other catch options for WBSS herring options this procedure (Section 3.10) needs to be followed once the option for catch of WBSS herring has been finalised.

It has become increasingly clear that in previous years, large parts of the catches reported for IIIa were actually taken in the North Sea. For 2004, Norway was allowed to transfer all of its quota in IIIa to IV, while the EC could transfer 50% of its quota. For 2005, Norway could again transfer 50% of its quota in IIIa to IV, while the EC now cannot (See Section 3.10). Furthermore, the last 3 year classes of NSAS have been weak, implying relatively smaller amounts of NSAS in IIIa. Therefore, it seems likely that the current fleet behaviour, with relatively small catches of NSAS in IIIa, will continue in the coming year.

¹ Preliminary

 $_{\rm 2}$ Landings from the Thames estuary area are included in the North Sea catch figure for UK (England).

³ Discards partly included in unallocated

⁴ May include misreported catch and discards.

⁹ Figures verified and altered if needed in 2003 by SG Rednose (ICES 2003/ACFM:10)

¹⁰ Figure altered in 2002 (was 7851 t higher before)

¹¹ Thames/Blackwater herring landings: 107 t, others included in the catch figure for The Netherlands

¹⁴ Figure altered in 2004

Includes catches in directed fishery and catches of 1-ringers in small mesh fishery up to 1992. 2 IVa,b and EC zone of IIa. 3 Provided by Working Group members. 4 Incomplete, only some countries providing discard information. Discards might also be included in un. 5 Includes spring spawners not included in assessment. 6 Revised during 1991. 7 Based on F=0.3 in directed fishery only; TAC advised for IVc, VIId subtracted. 8 Estimated. 9 130-180 for spring spawners in all areas. 10 Based on sum-of-products (number x mean weight at age). 11 Status quo F catch for fleet A. 12 The catch should not exceed recent catch levels. 15 During the middle of 1996 revised to 50% of its original agreed TAC. 14 Included in IVa,b. 15 Managed in accordance with autumn spawners. 17 Figure altered in 2001 and again in 2004. 18 Data for 1995-2001 were verified and amended where necessary by SG REDNOSE in 2003. 19 Fleet D and E are merged from 1999 onwards. 20 These catches (including local fjord-type Spring Spawners) are taken by Norway under a separate quota south of 62°N and are not included in the Norwegian North Sea catch figure for this area. 21 figure altered in 2003 to account for earlier summarizing errors. 22 See catch option tables for different fleets. Shaded cells for the catch by fleet in Division IIIa indicate persisting inconsistencies which have to be resolved intersessionally.

^{*}Figures for 1991-1999 altered in 2002 but the 1991-1995 updated figures were still not included in the assessment.

Table 2.2.12: Sampling of commercial landings of Herring in the North Sea (Div. IV and VIId) in 2004 by quarter. Sampled catch means the proportion of the reported catch to which sampling was applied. It is limited to 100% but might exceed the official landings due to sampling of discards, unallocated and misreported catches. It is not possible to judge the quality of the sampling by this figure alone. Note that only one nation sampled their herring by-catches in the industrial fishery (Denmark, fleet B) for age. Metiers are each reported combination of nation/fleet/area/quarter.

ICES HAWG Report 2005

Table 2.3.1.5 North Sea autumn spawners, estimates of (millions) at age from acoustic surveys, and SSB (thousands of tonnes) 1984-2004. For 1984-1986 the estimates are the sum of those from the Division IVa summer survey, the Division IVb autumn survey, and the Divisions IVc, VIId winter survey. The 1987 to 2000 estimates are from the summer survey in Divisions IVa,b, and IIIa excluding estimates of Division IIIa/Baltic spring spawners. For 1999 & 2000 the Kattegat was excluded from the results because it was not surveyed. The 1996 to 1999 surveys have been revised due to changes in methods for calculating mean weight and proportion adult. The earlier surveys were revised in March 2002 following recent reorganisation of archive, removal of a 9% calibration error on Scottish survey 1999-2000. In 2003 the area was extended to include part of area IVc and provide better coverage for sprat, the increase in biomass due to this change in area was negligible at 0.05%.

Table 2.3.2.5: North Sea autumn spawners. Time-series of the Multiplicative Larval Abundance Index (MLAI). The original MLAI is given in the second column. MLAI $_{plus}$ is the sum of the MLAI and the value of the reference area (Orkney/Shetlands, 1^{st} - 15^{th} September 1972). This estimate is then unlogged (eMLAI) and divided by 100 (MLAI $_{assess}$). The MLAI $_{assess}$ describes the time-series that is used in the assessment.

Extended Survivors Analysis

Autumn spawning herring in IV

CPUE data from file fleet.txt

Catch data for 45 years. 1960 to 2004. Ages 0 to 9.

First Fleet Last First Last Alpha Beta year year age age Acoustic survey 1-9+ 1989 2004 1 8 0.54 0.56 1 5 0 0 IBTS: 1-5+ wr 1979 2004 0.08 0.17 MIK 0-wr 1977 2004 0.08 0.17

Time series weights :

Tapered time weighting not applied

Catchability analysis :

Catchability dependent on stock size for ages < 2

Regression type = C

Minimum of 5 points used for regression

Survivor estimates shrunk to the population mean for ages < 2

Catchability independent of age for ages >= 4

Terminal population estimation :

Survivor estimates shrunk towards the mean F of the final 5 years or the 1 oldest ages.

S.E. of the mean to which the estimates are shrunk = 2.000 Minimum standard error for population estimates derived from each fleet = .300 Prior weighting not applied

Tuning converged after 26 iterations

Name of the SSB index file (Enter if none) -->
                                                   ssb.txt
No of years for separable constraint ?
Reference age for separable constraint ?
                                      -->
                                            4
Constant selection pattern model (Y/N) ?
                                            1.000000000000000
S to be fixed on last age ?
                                      -->
First age for calculation of reference F ?
                                      -->
                                            2
Last age for calculation of reference F ?
                                            6
Use default weighting (Y/N) ?
Enter relative weights at age
Weight for age 1-->
                   0.1000000000000000
Weight for age 2--> 3.17000000000000
Weight for age 7--> 0.75000000000000
Enter relative weights by year
Enter new weights for specified years and ages if needed
Is the last age of IBTS: 1-5+ wr a plus-group (Y/N) ?
Is the last age of MIK 0-wr a plus-group (Y/N) ?
You must choose a catchability model for each index.
Models: A Absolute: Index = Abundance . e
        L Linear: Index = Q. Abundance . e
P Power: Index = Q. Abundance^ K .e
where Q and K are parameters to be estimated, e is a lognormally-distributed
error.
Model for MLAI is to be A/L/P ?
Model for Acoustic survey 1-9+ wr is to be A/L/P ? -->L
Model for IBTS: 1-5+ wr is to be A/L/P ?
Model for MIK 0-wr \, is to be A/L/P ?
                                            -->T
Fit a stock-recruit relationship (Y/N) ?
Enter the time lag in years between spawning and the stock size of fish aged 0
years on 1 January. This will probably be 0 unless the stock is an autumn-spawning herring in which case it will probably be 1 years.
Enter the lag in years (rounded up)
                                      --> 1
Enter lowest feasible F
                                      --> 2.000000000000000E-02
Enter highest feasible F
                                      --> 2.000000000000000

3 Herring in Division IIIa and Subdivisions 22–24

3.1 The Fishery

3.1.1 ACFM advice and management applicable to 2004 and 2005

At the ACFM (May) meeting in 2004, it was stated that the status of the stock is unknown relative to safe biological limits, because reference points have not been determined. Although the assessment is uncertain SSB has been slightly increasing over the last four years. Fishing mortality is uncertain, but estimates for 2003 are 0.38 for adults and 0.12 for juveniles (0- and 1- ringers), which is slightly greater than \mathbf{F}_{max} .

ACFM recommended that since the current fishing mortality has lead to a stable or increased SSB, the fishing mortality should not be allowed to increase. This would correspond to catches in 2005 less than 92,000 t. According to the recent geographic distribution of catches, approximately half of the total catches should be taken from Subdivisions 22-24.

The EU and Norway agreement on a herring TACs set for 2005 was 96,000 t in Division IIIa for the human consumption fleet and a by-catch ceiling of 24,150 t to be taken in the small mesh fishery.

In previous years the International Baltic Sea Fishery Commission (IBSFC) set no special TAC for sub-division 22-24. In 2005, a TAC was set for the first time on the Western Baltic area the stock component. The TAC for 2005 was set at 46,000 t.

3.1.2 Catches in 2004

Herring caught in Division IIIa are a mixture of North Sea autumn spawners (NSAS) and Western Baltic spring spawning herring (WBSS). This Section gives the landings of both North Sea autumn spawners and Western Baltic spring spawners, but the stock assessment applies only to the spring spawners.

Landings from 1985 to 2004 are given in Table 3.1.1. In 2004 the total landings decreased to 94,200 t in Division IIIa and Subdivisions 22–24 compared with 2003 where the landings were 109,500 t, resulting in a landing figure for 2004 at the lowest level for the whole timeseries. In 2004, 20,500 t were taken in the Kattegat, about 31,700 t from the Skagerrak and 42,000 t from Subdivisions 22–24. These landings represent a decrease of 15,200 t compared to 2003 and 34,700 t compared to 2002. The Danish national management regime for herring and sprat fishery in Subdivision 22 was changed in 2002. It should be noted that the total landings for fishery in Skagerrak have been updated for 1995-2001 because of Norwegian misreporting of landings taken in the North Sea and reported to Skagerrak. This was also delt with in 2002 and 2003 but was not thought to occur in 2004.

The German landings in 2004 were at the same level as in 2003. Since 2001 the fishery behaviour changed in the German fleet. In former years the dominant part of herring was caught in the passive gears, gillnets and trapnets. The share of herring, which was caught by trawlers in the area off the Rügen Island coast up to the Arcona Sea (Subdivision 24), increased from 26% in 2001 to 52% in 2004. This change was caused by new requirements for a new fish factory on Rügen Island. This factory expects to process 50,000 t per year and started during autumn 2003.

In 2004 the landing data are calculated by fleet according to the fleet definitions used when setting TACs.

The fleet definitions used since 1998 are:

- **Fleet C**: directed fishery for herring in which trawlers (with 32 mm minimum mesh size) and purse seiners participate.
- Fleet D: All fisheries in which trawlers (with mesh sizes less than 32 mm) and small purse seiners, fishing for sprat along the Swedish coast and in the Swedish fjords, participate. For most of the landings taken by this fleet, herring is landed as by-catch. Danish and Swedish by-catches of herring from the sprat fishery and the Norway pout and bluewhiting fisheries are listed under fleet D.
- **Fleet F**: Landings from Subdivisions 22–24. Most of the catches are taken in a directed fishery for herring and some as by-catch in a directed sprat fishery.

In table 3.1.2 the landings are given for 2001 to 2004 in thousands of tonnes by fleet and quarter

3.2 Biological composition of the catch

The level of sampling of the landings for human consumption and the industrial landings was generally acceptable in the Skagerrak and Kattegat and Subdivisions 22-24. Where sampling was missing in areas and quarters on national landings, sampling from either other nations or adjacent areas and quarters were used to estimate catch in numbers and mean weight-at-age (see Table 3.2.17).

Table 3.2.2 and Table 3.2.3 show the total catch (autumn and spring spawners) in numbers and mean weight-at-age for herring by quarter and fleet landed from Skagerrak and Kattegat, respectively. The total numbers and mean weights-at-age for herring landed from the Kattegat, Skagerrak and Subdivisions 22 - 24 by fleets are shown in Table 3.2.10.

Based on the proportions of spring- and autumn spawners (see Section 3.2.1 and Section 3.2.2) in the landings, number and mean weights by age and spawning stock are calculated. The total numbers and mean weight of the NSAS landed from Kattegat and Skagerrak by quarter and fleet is shown in Table 3.2.4 and 3.2.6. The total numbers and mean weight of the WBSS landed from Kattegat and Skagerrak by quarter and fleet are shown in Table 3.2.5 and 3.2.7.

The total numbers and mean weight of the NSAS by quarter and fleet landed from Division IIIa are shown in Table 3.2.8 and the WBSS in Table 3.2.9.

The total catch in numbers of WBSS in Division IIIa and the North Sea are shown in Tables 3.2.11 and 3.2.12 (see also Tables 2.2.1 – 2.2.5). The landings (SOP) of the WBSS taken in Division IIIa and the North Sea in 2004 were estimated to be about 35,078 t (Table 3.2.15) compared to about 37,075 t in 2003 and 53,544 t in 2002. This slight decrease in landings (SOP) was mainly due to a decrease in the estimated number of 1 group spring spawners in Skagerrak and Kattegat. The landings (SOP) of NSAS in Division IIIa amounted to 24,214 t compared to 32,498 t in 2003 and 26,205 t in 2002 (Table 3.2.13). The total catch in number and mean weight-at-age of WBSS in the North Sea, Division IIIa and in Subdivisions 22–24 for 1991–2004 are given in Tables 3.2.14 and 3.2.15.

3.2.1 Quality of Catch Data and Biological Sampling Data

Misreporting of fishing area still occurs. There is uncertainty about where the Danish landings for human consumption, reported from Division IIIa were actually taken. There is a high probability that these catches have been taken in the North Sea. Therefore, these catches have been transferred to the North Sea. The Norwegian landings reported as having been taken in Skagerrak for the period 1995 to 2003 may have been caught in the North Sea and have been transferred to the North Sea. However, due to changes in the Norwegian management the catches reported from Skagerrak in 2004 are reliable. Some landings, reported as taken in this

triangle, (an area in the southern Kattegat, which is a part of the Baltic area: Gilleleje, DK - Kullen, S - Helsingborg, S - Helsingør, DK), may have been taken outside this area. These landings are listed under Kattegat.

No estimates of discards were available to the Working Group. The amount of discards for 2004 is regarded as being insignificant.

Sampling for species composition in the small-meshed fishery has been carried out as in previous years. Sampling in this section only refers to sampling for length, weight and age information.

Table 3.2.16 show the number of fish aged by country, area, fishery and quarter. The total landings from Division IIIa and Subdivisions 22-24 were 94,200 t from which 352 samples were taken, 34,581 fish were measured and 18,611aged. For comparison, for 2003 where 109,500 t were landed from which 292 samples were taken, 30,500 fish measured and 14,800 fish aged.

Although the overall sampling more than meets the recommended level of one sample per 1000 t landed per quarter, there is an unequal coverage of some areas and times of the year.

There is an unknown effect of variability in the stock composition in Division IIIa due to uncertainty of the splitting factor between the NSAS and the WBSS. There is at present no information about the relevance of local herring stocks in relation to the fisheries (i.e. the Kattegat autumn spawners and the Skagerrak winter or spring spawners) and their possible influence on the stock assessment. Recent evidence from genetic differentiation among spawning aggregations in the Skagerrak suggests a potential high representation of these local spawning stocks (see section 1.4.4).

3.2.2 Stock composition in the catch

Catches of herring in the Kattegat, the Skagerrak and the Eastern part of the North Sea are taken from a mixture of two main spawning stocks mainly 1+ ringers of the Western Baltic spring spawners and 0-2-ringers from the North Sea autumn spawners, including winterspawning Downs herring (see stock annex). As in recent years the WG uses the analysis of individual otolith microstructure for determination of spawning type in age-class stratified random sub-samples of herring in Division IIIa (see stock annex).

For the present year the otolith-based method has been exclusively applied for the Division IIIa split. For Subdivisions 22, 23 and 24 it was assumed that all individuals caught belong to the WBSS stock, even when otolith microstructure indicate occurrence of autumn spawners in the surveys or in samples of landings (see stock annex).

Sampling levels in 2004 were high enough to allow the split to be applied to their respective spatial and temporal origin without reallocating between the landings and the surveys or between areas or quarters. Sampling of individual older age classes is generally scarce and analyses were pooled in combined age groups to achieve at least 12 individual otolith microstructure estimates per age group (Table 3.2.1).

3.2.2.1 Spring-spawning herring in the North Sea

Catches from the transfer area within Subdivision IVa East and Division IVb are usually split by analyses of Norwegian samples (see Figure 2.2.2). Norwegian samples were only available for herring caught in the 2nd quarter. For 1-ringers it was assumed that all fish were autumn spawners. For 2-ringers, 3-ringers, and 4+-ringers, mean vertebral counts in the transfer area were used (see stock annex). For the 3rd quarter no Norwegian samples were available for landings from the transfer area and instead the otolith-based proportions from the Danish acoustic survey from the same area were applied to the age distributions. The quarterly age

distribution and mean weight-at-age in Subdivision IVa East was applied to the catches of the second and third quarters in the transfer area. The numbers of spring spawners by age were obtained by applying the estimated proportion by age. For the actual split and catch in the transfer area see Section 2.2.2.

3.2.2.2 Autumn spawners in Division IIIa

For commercial landings in 2003 the split of the Swedish and Danish landings was conducted using the proportion by age in the combined samples of Swedish and Danish microstructure analyses. The estimation of the proportion spring and autumn spawners in the landings from Division IIIa was performed on the basis of totally 3489 (2674 Danish and 815 Swedish) otolith microstructure analyses in 2004. Data were disaggregated by area (Kattegat and Skagerrak), age group and quarter (1–4). The proportions and the analysed numbers are presented in Table 3.2.1. In the acoustic survey in quarter 2 and 3 in Division IIIa and VIa East, 1163 otoliths were analysed and applied for the split of this survey, 389 otoliths from the survey in the VIa East area were further used to split catches taken in the 3rd quarter in the transfer area (see section 3.2.2.1). In the 2004 Division IIIa IBTS survey in the 3rd quarter 226 otoliths were analysed and in the 2005 Division IIIa IBTS survey in the 1st quarter 192 otoliths were analysed.

3.2.2.3 Autumn spawners in the fishery in Subdivisions 22 to 24

All herring found in subdivisions 22-24 are treated as Western Baltic spring spawners independent of spawning type from otolith micro-structure analysis (see stock annex).

3.2.2.4 Accuracy and precision in stock identification

To test both precision and accuracy otolith microstructure analyses were compared among the three Danish readers on material from spawning populations sampled under the EU project HERGEN (QLRT – 2000 – 01370). Assuming that herring spawn during the same season in which they were hatched themselves, a high accuracy would imply a high correspondence between estimated spawning type and sampling season for the spawning populations (herring stage 6 maturity). Spawning season was initially estimated as either autumn, winter, or spring, but for the comparison autumn and winter were pooled into one group. Precision was estimated both as within reader repeatability and among reader correspondence. 168 otoliths were available in the analysis representing 63 spring and 105 autumn/winter spawners. Otoliths considered as unreadable by one or both readers were disregarded for that comparison, between 4 and 8 otoliths were dismissed in each comparison.

	SPRING	AUTUMN/WINTER		SPRING	AUTUMN/WINTER
Reader1 vs season	97%	100%	Reader1 vs Reader2	77%	89%
Reader2 vs season	80%	86%	Reader1 vs Reader3	100%	99%
Reader3 vs season	95%	100%	Reader3 vs Reader2	77%	92%

Reader 2 had an internal agreement between two reading of the same 50 otoliths of 81% and 93% on autumn/winter and spring spawners respectively, whereas reader 3 had 97% and 100% agreement on autumn/winter and spring spawners respectively. A generally high agreement was found between readers 1 and 3, whereas both among and within reader variability indicated some uncertainty with regards to readings by reader 2. A closer analysis of the results from this reader pointed at misinterpretations of winter spawners assigned as spring spawners. The problem is being corrected and is not considered to influence splitting results to a high degree since readers 1 and 3 performed by far the most readings in the routine analyses for 2004.

Danish, Swedish and German otolith microstructure analyses are regularly double checked by the same Danish expert reader for consistency in interpretation. The overall impression is a good agreement among readers implying a potential high accuracy in the splits.

Results presented to the WG on mixed stock analysis exploiting genetic variation in herring from Division IIIa in 2002 and 2003, show excellent agreement between assignments based on micro satellites and otolith microstructure (Bekkevold pers. commun. HERGEN QLRT - 2000 – 01370; see also section 1.4.4) indicating good accuracy of the split between North Sea on the one hand and local stocks plus Western Baltic herring on the other hand. The possibility of combining genetics and otolith analyses for a higher resolution of the Skagerrak, Kattegat and Western Baltic stocks is presently being explored.

3.3 Fishery-Independent Information

3.3.1 International Bottom Trawl Survey in Division IIIa

The survey indices were split into spring and autumn spawning components by microstructure analysis of otoliths (section 3.2.2) except for 2001 3rd quarter and 2002 1st quarter when vertebrae counting methods were used. The estimates of the abundance by age of the spring spawning component in the Kattegat are presented in Table 3.3.1 and Table 3.3.2. The mean value for 1-ringers in 2005 1st quarter is the third lowest observed in the time-series and follows the lowest values in 2004.

3.3.2 Summer acoustic survey in Division IIIa

The acoustic survey from 30 June to 10 July 2004 covered the area in the Skagerrak and the Kattegat. Details of the survey are given in the 'Report of the Planning Group for Herring Surveys' (ICES 2005/G:04). The estimated spawning biomass (3+) of Western Baltic spring spawning herring in 2004 was about 179,000 tonnes, showing an increase compared to the previous year but well below the level of the beginning of the 1990's. The results from this survey are summarised in Table 3.3.3.

3.3.3 Autumn acoustic survey in western Baltic and the southern part of Division IIIa (Kattegat)

A joint German-Danish acoustic survey was carried out with R/V "SOLEA" between 29 September and 18 October 2004 in the Western Baltic covering Subdivisions 21, 22, 23 and 24. A full survey report is given in the Report of the Planning Group for Herring Surveys (ICES 2005/G:04). The results for 2004 are presented in Table 3.3.4. The herring stock was estimated to be about 172,000 tonnes in Subdivisions 22-24 (Table 3.3.4). This is comparable to the last year estimate.

3.3.4 Larvae surveys

The estimated numbers of larvae for the period 1977 to 2004 are summarised in Table 3.3.5. The 2004 estimate of the larvae index (see stock annex) is smaller than the previous year's estimate but above the low values estimated during the beginning and middle of the 1990's.

3.4 Mean weights and Maturity at age in the Stock

Mean weights at age in the catch in the 1st quarter were used as stock weights (Table 3.2.11). The maturity ogive was assumed constant between years. The same maturity ogive was used as in the HAWG 2004:

W-RINGS	0	1	2	3	4	5	6	7	8+
Maturity	0.00	0.00	0.20	0.75	0.90	1.00	1.00	1.00	1.00

3.5 Recruitment estimates

Indices of 0-ringer abundance of the Western Baltic spring spawning herring in Sub-divisions 22-24 for 2004 were available from the larval surveys during the spawning season on the main spawning area (Table 3.3.5) and from the Acoustic survey (September/October). Log transformed indices were compared by year class in Figure 3.5.1. Historical high recruitment of the 1998 and 1999 year-classes were supported by 0-ringer and 1-ringer indices in the acoustic survey in Sub-divisions 22–24 (Table 3.3.4). The larval index and the 0-ringer from the acoustic survey showed very similar trends in the last 5 years.

3.6 Stock Assessment

3.6.1 Input data

Catch in numbers at age from 1991 to 2004 were available for Sub-division IVa (East), Division IIIa and Subdivisions 22-24 (Table 3.6.1) and as proportion at age (Figure 3.6.1). Catches were updated for 2004. Years before 1991 have been excluded due to lack of reliable data for splitting spawning type and to a large change in fishing pattern caused by changes in the German fishing fleets.

Mean weights at age in the landings are found in Table 3.6.2 and in Figure 3.6.2. The proportions of F and M before spawning was assumed constant between years. F-prop was set to be 0.1 and M-prop 0.25 for all age groups. Natural mortality was assumed constant at age and equal to 0.3, 0.5, and 0.2 for 0- ringers, 1- ringers, and 2+ ringers respectively (Table 3.6.4). The estimates of predation mortality were derived as a mean for the years 1977–1995 from the Baltic MSVPA (ICES 1997/J:2).

Available survey indices were:

FLT1: Hydroacoustic survey in Division IIIa and Subdivision IVa East, July 1991–2004, 0–8+ringers

FLT2: Hydroacoustic survey in Subdivisions 22, 23 and 24, Oct. 1991–2004, 0–8+ ringers

FLT3: IBTS in Division IIIa, Quarter 1, 1991-2005, 1-5 ringers

FLT4: IBTS in Division IIIa, Quarter 3, 1991-2004, 1-5 ringers

FLT5: Larvae survey in Subdivision 24 (Greifswalder Bodden), March-June 1977-2004

All are age-structured indices with FLT5 used as an index of recruiting 0-ringers. None of the indices covered the total spatial distribution of the WBSS stock and the indices covered the following quarters and areas:

SURVEY AREA	QUARTER 1	QUARTER 2	QUARTER 3	QUARTER 4
Division IIIa	FLT3		FLT1 and FLT4	
Sub-divisions 22- 24	FLT5	FLT5		FLT2

Subsets of these data series representing selected age groups were constructed to give a better representation of the stock (see section 3.6.3).

3.6.2 ICA settings

The following settings were used in 2005, similar to 2004:

- The period for the separable constraint: 5 years (2000-2004).
- The weighing factor to all indices (lambda = 1).

- A linear catchability model for indices 1,2,3, and 4, and both linear and power model for index 5.
- The reference F set at age 4 and the selection=1 for the oldest age.
- The catch data were down-weighted to 0.1 for 0-ringer herring.

3.6.3 Exploration by individual survey indices

Exploratory runs of catch data with single indices were performed using the general ICA-setting mentioned earlier (Section 3.6.2). A summary of the results from these runs is presented in Figures 3.6.3 and 3.6.4.

The runs with the larval survey index only including all years and using a linear model did not exhibit a realistic F value, whereas the power model was more in line with other individual indices. However, the recent history of exploratory runs for the larval survey has shown large variation in estimated F and it may still be too early to judge their robustness for use in the final assessment.

The IBTS in Kattegat Q1 (FLT3) indicate a very high F of 0.8, whereas the hydroacoustic survey indices in Division IIIa (FLT1a and FLT1b), the Acoustic survey in Subdivisions 22-24 (FLT2a and FLT2b) and the IBTS in Kattegat Q3 (FLT4) suggest more intermediate Fs of 0.6, 0.3 and 0.2 respectively. On the other extreme the larval survey in Subdivision 24 (FLT5a and FLT5b) give indications of quite low fishing mortality depending on the chosen model, power- (F~0.1) and linear catchability (F~0.03).

The larvae survey FLT5 (N30) predicts strong and weak year classes very well but does not reflect the actual magnitude of year class strength. This results in a strong correlation, but large residuals when fitted in the ICA model to the catch data. A longer time-series may help resolve these issues, particularly if intermediate N30 values appear in the time-series. Although the larval survey does not add information to the current specification of the ICA model, it appears to function well as an indicator of recruitment. Trends in log transformed values of recruitment indices (larval index total time-series, 0-ringer Acoustic in SD 22-24 and 1-ringer Acoustic in SD 22-24) show good concordance in the recent seven years (Figure 3.5.1). In the North Sea, the long MIK time-series (on post larvae) works well as an indicator of 0 ring year class strength in the ICA model. The larvae N30 is an abundance index of post-larvae in some ways similar to the MIK index, so potentially maybe of use in the future. The N30 index provides extremely valuable information on the general biology and year class development of the WBSS herring population.

The tuning fleet choice and the settings for the final ICA run for the 2005 assessment were the same as in the last two years assessments with fleets FLT1b, FLT2b, and FLT4. The biological reasoning behind the choice of indices with restricted numbers of age classes is that there is only a partial migration of age 0-1 ringers to the Division IIIa in the summer and that ages older than 5-ringers are poor represented in the Subdivision 22-24 acoustic surveys and in the IBTS.

3.6.4 Final Assessment

This assessment conforms to an update assessment of WBSS herring, input data (years 1991-2004, Ages 0-8+ ringers) are given in the following tables:

- Catch in number (Table 3.6.1)
- Weight in catch (Table 3.6.2)
- Weight in stock (Table 3.6.3)
- Natural mortality (Table 3.6.4)
- Maturity (see text table in section 3.4)

The following surveys were included (Tables 3.6.5a-c):

- FLT 1b: DK Hydroacoustic survey in Division IIIa+ SD IVaE, July 1991–2004, excl. 1999, 2–8+ ringers
- FLT 2b: GER Hydroacoustic survey in Subdivisions 22, 23 and 24, Oct 1991–2004, 0–5 ringers
- FLT 4: IBTS in Kattegat, Quarter 3, 1991-2004, 1–5 ringers

The final model settings are shown in Table 3.6.6. The output data are given in Tables 3.6.7-3.6.16. The estimated SSB for 2004 is about 180,000 tonnes with a mean fishing mortality (ages 3-6) of 0.36 (Table 3.6.9). The model diagnostics show a rather well defined minimum SSQ response-curve for all age-indices except age-index 1 (Acoustic Survey in Division IIIa+IVaE) that is somewhat flat (Figure 3.6.5). The minimum SSQ for the Acoustic Survey in SD 22-24 (age-index 2) finds an intermediate compromise between the high F of age-index 1 (Acoustic Survey in Division IIIa+IVaE) and the low F of age-index 3 (IBTS Kattegat Q3). The stock summary is shown in Figure 3.6.6 and Table 3.6.9.

The marginal totals of residuals between the catch and the separable model are overall small, with almost no residuals for younger ages and slightly larger residuals at older ages 4-7 as well as a reasonably trend-free separable period (2000-2004). Year effects repeat the somewhat large positive and negative values for 2001 and 2003 respectively (see Figure 3.6.7), but as already noted in last years assessment most of the year effects are again caused by 0-ringers that are down-weighted in the analysis but still appears with full weight in the residual plots of the ICA diagnostics. For values see Table 3.6.12.

The diagnostics for the three surveys repeat the trend of low acoustic and high IBTS residuals for 2003 seen in last years assessment, whereas values for 2004 are much closer to model predictions although they reflect the same type of balance between acoustic and IBTS surveys. The Acoustic Survey in Division IIIa+IVaE and the Acoustic Survey in SD 22-24 showed in general negative residuals for 2004 except for 2 ringers in both surveys (Figure 3.6.11). This was balanced by similar sized but positive residuals for all ages in the IBTS Kattegat Q3 survey.

The catch-at-age unweighted variance component is of the same magnitude as the individual acoustic survey variance components and smaller than the IBTS survey component (Table 3.6.16), however in the unweighted statistics down-weighting of the 0-ringers is not accounted for, and this age contribute quite some variation with a C.V. of 50% compared to about 15% for the 2+ groups (Table 3.6.10). After a decrease from a period of high fishing mortality in the mid 1990s, the F_{3-6} values in the recent 5 years are estimated to have decreased from 0.56 to 0.36. The SSB shows a slight increasing trend over the recent years after a marked decline in the mid 1990s.

The fit of the surveys to the population number by age class is similar between the Division IIIa acoustic survey (Figures 3.6.8a-g) and Subdivisions 22-24 acoustic survey (Figures 3.6.9a-f) (FLT1b and FLT2b respectively). Both surveys exhibit the best fit for intermediate ages 3-5 ringers, and neither survey has an annual trend in residuals although Subdivisions 22-24 acoustic survey has lower catchability values than the Division IIIa survey (Table 3.6.11). On the other hand, the Kattegat Q3 IBTS-index (FLT4) shows quite poor fit of catchabilities for the age classes 1-3 ringers but improving for the two oldest ages 4 and 5 ringers in the index (Figures 3.6.10a-e). The reason for the poorer performance of the Kattegat Q3 IBTS survey may be an increased redistribution of immature age-classes into the Kattegat area in the recent two or three years.

Overall trends in the age structured data for the ICA model

Exploring the cohort dynamics by log catch and log survey indices gives an indication of overall mortality and catchability in successive cohorts from year classes 1991-2000 (Figures 3.6.8a-d). Slopes of log catches do not indicate any increasing trend in mortality (Figure 3.6.12a). Slopes from the Division IIIa acoustic survey and from the Subdivision 22-24 acoustic survey are relatively stable (Figure 3.6.12b and Figure 3.6.12c), whereas for IBTS in Kattegat it shows fluctuation with initially increasing negative values followed by decreasing negative slopes from the 1994 cohort (Figure 3.6.12d).

Generally however, the trends may be interpreted as an overall stable to decreasing fishing mortality from 1994. The signal from the catches is relatively stable whereas the survey indices are more scattered and somewhat conflicting, but together provide a compromise in line with the catch information.

3.7 Short-term Projection

The assessment was used to provide a yield-per-recruit plot for WBSS herring in Division IIIa and Subdivisions 22-24 (Figure 3.7.1). The values for $\mathbf{F}_{0.1}$ and \mathbf{F}_{max} are 0.21 and 0.43, respectively.

Short-term predictions were carried out using MFDP v.1a software. ICA estimates of population numbers and fishing mortalities were used except for the numbers of 0-ringers in 2004-2007, where the geometric mean of the recruitment over the period 1993–2002 was taken, and for the numbers of 1-ringers in 2005, where the geometric mean over the period 1994-2003 was used. Mean weights-at-age in the catch and in the stock were taken as a mean for the years 2002–2004. A *status quo* fishing mortality for 2005 onwards was assumed, with values rescaled to the last year estimate. Input data for catch predictions are presented in Table 3.7.1.

Short-term predictions were carried out assuming a *status quo* fishing mortality for 2005 onwards. The single option table is available for 2005 to 2007 (Table 3.7.2).

SCENARIO	2005	2006	2007
1) status quo F	$F_{2005} = F_{2004} = 0.36$	$F_{2005} = F_{2004} = 0.36$	$F_{2005} = F_{2004} = 0.36$
	Status quo F	Status quo F	Status quo F
	Catch = $91,900 \text{ t}$	Catch = $95,400 \text{ t}$	Catch = $101,500 \text{ t}$

The results of the short-term predictions are given in Tables 3.7.2 – 3.7.4. Table 3.7.2 shows single option predictions for 2005-2007 and Table 3.7.3 multiple options for 2006 at *status quo* fishing mortality in 2005. The catches for 2006 and 2007 at *status quo* fishing mortality were predicted to be 95,400 t and 101,500 t, respectively, which is an overall increase in relation to the current catch level of 76,800 t. The SSB is predicted to increase to 220,000 t in 2006 and to 233,000 t in 2007.

Based on *Status quo* F and $F_{0.1}$ (0.36 and 0.21 respectively) the predictions of SSB_{2006} (233,000 t and 266,000 t respectively) are well both above the lowest observed in the time series from 1991-2004 (SSB_{1998} 116,000 t).

3.8 Reference Points

Reference points have neither been defined nor proposed for this stock. The time series is short with revised catch data and reliable splitting factors for only 14 years, the estimated SSB has not been below 116,000 t since 1991 and there is no obvious stock-recruitment relationship.

3.9 Quality of the Assessment

This year's assessment is an update of last year's assessment. Therefore, the assessment has not been explored beyond examining the standard diagnostics.

Three data series are now used in addition to the catch numbers at age. None of these surveys cover the whole distribution area of the stock, but each of them cover areas where it is likely that certain ages are well represented at survey time. The acoustic survey in Division IIIa+IVaE covers fish age 2 and older while the two others largely cover the younger part of the population. Hence, these surveys can be regarded as complementary. All surveys are noisy, with strong year effects. The acoustic survey in Division IIIa+IVaE indicates a higher mortality than the others, but its contribution to the total sum of squares does not have a distinct minimum.

The retrospective errors are small, except in the recruitment. Apparently, the strength of a year class is not firmly estimated before the year class has been followed for 2-3 years. The selection at age in the fishery changes in retrospective runs. This probably reflects a stronger exploitation of younger herring prior to 1999, which in the present assessment is reflected in the VPA part. The selection at age in this year's assessment is virtually equal to that in last year's assessment, and the catch residuals are small. Hence, the separable assumption does not seem to be violated.

Altogether, the current procedure for assessing the stock has given consistent results with respect to fishing mortality and spawning biomass for several years. Compared to last year's assessment, the change in the estimate is +1% for the fishing mortality in 2003 and -2% for the SSB in 2003.

For prediction purposes better indicators of recruitment would be useful. At present, geometric mean recruitment has to be assumed for age 1 in the intermediate year and for later year classes. The larval survey index has been considered previously as a candidate recruitment indicator, but including it in the assessment as another tuning series was not successful. It does identify most strong and weak year classes, however. Using it as a semi-quantitative support for the assumptions about recruitment in the predictions may be considered as an alternative. This would need further exploration with this purpose in mind. It is suggested to search for procedures that give a better predictive power of the recruitment by reducing the impact of outliers, and also to examine the raw data for area subsets that may reflect the year class strength better.

The predictions are made for the Western Baltic Spring Spawning (WBSS) stock, while management is by areas. In Division IIIa, the fishery exploits both WBSS and North sea autumn spawning herring. The Working Group has attempted to outline the consequences for both stocks in fishery in Division IIIa (Section 3.10). This requires insight in both how the catches of WBSS is distributed on areas, and in the proportions of the catches in Division IIIa from each stock. Both these relations change over time, and are influenced both by managers decisions and the abundance of the respective stocks in the area. So far, the only basis has been historical data of catches in biomass by area and species (cfr. Table 2.1.6). A better basis could be achieved by considering catches at age, and through further investigations of how management decisions influence the fishery. This would require inter-sessional work.

The text table below gives an overview of the assumptions made in the 2004 and 2005 assessments and a comparison of the main results.

CATEGORY	PARAMETER	ASSESSMENT 2004	ASSESSMENT 2005	DIFF. (+/-) %
ICA input	No. of years for separable constraints	5	5	No
	Reference age for separable constraint	4	4	No
	Selection to be fixed on last age	1	1	No
	Weighting factor to all indices	1	1	No
	Catch down- weighted to 0.1 for 0- ringer	Yes	Yes	No
	Tuning data	Acoustic Surv. Div. IIIa 2-8+ ringers	Acoustic Surv. Div. IIIa 2-8+ ringers	No
		Acoustic Surv. SDs 22- 24 0-5 ringers	Acoustic Surv. SDs 22- 24 0-5 ringers	No
		IBTS Surv. Quarter 3 1-5 ringers	IBTS Surv. Quarter 3 1-5 ringers	No
ICA results	SSB 2003 F(3-6) 2003	157,600 t 0.385	154,970 t 0.389	-2% +1%

3.10 Management Considerations

Catch options for mixed stocks in Division IIIa based on short term predictions for WBSS

During last year's HAWG management considerations for the Western Baltic spring spawning stock (WBSS) was elaborated taking into account the mixed stock nature of the catches in Division IIIa. Before 2004 the main constraint on the fishery in Division IIIa was the concern for the North Sea autumn spawning herring (NSAS). This situation has changed since the NSAS herring at least at present is in a good state. Hence, quotas in Division IIIa, which include both stocks, may have to be constrained by the need to restrict the exploitation of WBSS, which are taken together with NSAS in this area.

It should, however, be noted that the scope for exploitation is continuously changing due to different population dynamics of the two stocks. In this perspective the WBSS 2003 year-class is indicated to be well above average whereas the three most recent year-classes of NSAS, 2002, 2003, and 2004 appear to be low.

The current fleet definitions are:

North Sea

Fleet A: Directed herring fisheries with purse seiners and trawlers. By-catches in industrial fisheries by Norway are included.

Fleet B: Herring taken as by-catch under EU regulations.

Division IIIa

Fleet C: Directed herring fisheries with purse seiners and trawlers

Fleet D: By-catches of herring caught in the small-mesh fisheries

The WBSS are exploited by other fleets as well, in Subdivision 22-24.

Quotas in Division IIIa

The quota for the C-fleet and the by-catch ceiling for the D-fleet are set for both stocks together. Therefore the implication of the quotas for the outtake of WBSS has to be considered. Furthermore the implication for the outtake of NSAS has to be taken into account when setting fleet wise quotas for that stock (see section 2.7).

In **2004** the agreed TAC for the directed fishery in Division IIIa (C-fleet) was 70,000 t. 500 t for the Faeroes, 60,200 t for the EU of which 50% could be taken in the North Sea, and 9,300 t for Norway of which 100% could be taken in the North Sea. With the regulations allowing these quota transfers from Division IIIa to the North Sea, the incentive to misreport might have decreased. Thus catches in 2004 reported from Division IIIa may in fact be real.

For **2005** the agreed TAC for the directed fishery in Division IIIa (C-fleet) is 96,000 t. This TAC is divided into quotas, 500 t for the Faeroes, 82,700 t for the EU of which all has to be taken in Division IIIa, and 12,800 t for Norway of which 50% can be taken in the North Sea. A by-catch ceiling for Division IIIa herring in the small meshed fishery (fleet-D) is set at 24,150 t for the EU fleet.

It may also be noted that a variable, but relatively small amount (up to about 8,000 t) of WBSS herring is taken in the fishery in Subarea IV (see sec. 2.2.2 and figure 2.2.2 for information about WBSS taken in Divisions IVa and IVb East). This component is accounted for in both the assessments on NSAS and WBSS. The situation is further complicated by misreporting by areas. In recent years, the HAWG in its calculations has assumed that a substantial part of the catch reported as taken in Division IIIa in fleet C actually has been taken in Subarea IV. These catches have been allocated to the North Sea stock and accounted under the A-fleet.

Data used for catch options in 2006

There is no firm basis for predicting the fraction of NSAS in the catches by the C-fleet in future years. It will to some extent depend on the abundance of each stock in the area, which for NSAS is related to the strength of incoming year classes (0-2 ringers), and for the WBSS the late juvenile and adult age classes (2+ ringers), but also to where and when the fishery is conducted.

Hence, to compute the catch of WBSS and NSAS by fleet in Division IIIa corresponding to a given total catch option for WBSS, the first step will be to estimate the amount corresponding to the C- and D- fleets.

However, the proportions of the two stocks as well as the distribution pattern of the fishery in the Eastern North Sea and the Division IIIa is dynamically changing year by year. This is influenced by year-class strength of the two stocks and their relative geographical distributions as well as fleet behaviour reacting on herring availability and management decisions. Directed intersessional work is needed to make further progress regarding catch predictions by stock for the different fleets.

Therefore the information used for catch options in 2006 is based on the 2004 share of the total catch for the involved fleets and the proportions caught of each stock.

The text table below shows the 2004 share of the total catch in t of WBSS by fleet.

WBSS	FLEET C (IIIA)	FLEET D (IIIA)	SD 22-24 + FLEET A (IV)	TOTAL
2004	16,825 (22%)	11,175 (15%)	48,815 (64%)	76,815

Next, this share is translated to total catch of herring of both stocks (NSAS and WBSS) for each fleet by accounting for the fraction of WBSS in the catches by these fleets.

The text table below shows the proportion WBSS in the catches by fleet in Division IIIa as well as for the fleets in SD 22-24.

WBSS	FLEET C	FLEET D	SD22-24 + FLEET A (IV)*
2004	0.56	0.51	1

^{*} Only WBSS caught in Subarea IV are accounted for in the calculations

From this, it also follows the amount of WBSS by each fleet corresponding to a certain catch option for the total catch of the WBSS stock. The algorithm can be outlined as follows:

- Start with a total catch of WBSS
- Allocate this WBSS catch to fleets based on the 2004 share to get the WBSS catch by the C- and D- fleets.
- Translate these fleetwise WBSS catches to catches of both stocks together by the C- and D- fleets, using 2004 data for the proportion of each stock in the C- and D- fleet catches, and further, derive the corresponding catches of NSAS by these fleets.

ICES catch predictions versus management TAC

ICES gives advice on catch options for each stock separately, whereas herring is managed by area (see the following text diagram).

	TAC	BY- CATCH CEILING	TAC	BY- CATCH CEILING	TAC	
	Div. IV	Div. IV	Div. IIIa	Div. IIIa	Sub-div. 22-24	
	Fleet A	Fleet B	Fleet C	Fleet D	All fleets	
ICES Advice	NSAS	NSAS	NSAS	NSAS		
	WBSS	WBSS	WBSS	WBSS	WBSS	ICES Advice

The way it was done in 2004. In response to a special EU request the HAWG2004 calculated the effect of TAC shares for Division IIIa for 2005. ICES in 2004 advised that catches for the total Western Baltic Spring Spawners (WBSS) in Division IIIa, IVa East, and SD 22-24 should not exceed 92,000 t. With the average (2001-2003) share of the WBSS catch taken by the C- and D-fleets of 44% and an amount of WBSS corresponding to its proportion of catches in the C-fleet of 0.58 and D-fleet 0.35 this would lead to a total TAC of 79,400 t in Division IIIa. However, the agreed TAC for 2005 in Division IIIa in the directed fishery (C-fleet) was set to 96,000 t, plus the by-catch ceiling (D-fleet) was set to 24,150, giving a total TAC of 120,150 t.

The HAWG 2005 procedure. Catch options based on presently set TACs in Division IIIa along with different shares expected to be taken in SD22-24 and in Subarea IV are compared with catch options derived from the HAWG2005 short-term predictions for the Western Baltic spring spawners in Division IIIa and SD 22-24.

Catches following present TAC for Division IIIa. Short-term predictions indicate a catch in 2006 of 95,000 t with F_{sq} . However, if a total TAC for 2006 in Division IIIa was to be set at 120,150 t for both stocks combined, as it presently is for 2005, then with the present proportions of WBSS and NSAS in the C- and D-fleet and different shares taken in SD22-24 and Subarea IV, this could lead to scenarios 1-3 in the following text table.

All three scenarios greatly overshoot the predicted catches with amounts depending on the rule of calculating the catch taken in SD 22-24 and Subarea IV:

- 1. using the fixed TAC of 46,000 t in SD 22-24 set by the IBSFC + 7000 t taken in Subarea IV
- 2. using equal shares of WBSS taken in Division IIIa and in SD 22-24 and Subarea IV
- 3. using the 2004 share (64%) of WBSS catches taken in SD 22-24 and Subarea IV

Catches following \mathbf{F}_{sq} . To reach total WBSS catches of 95,000 t in 2006, TACs should be lower than 120,150 t for Division IIIa, with values depending on the expected share of the catch taken in SD 22-24. Scenarios 4-6 in the table below have the same share of SD22-24 catches as 1-3, but Division IIIa TACs are calculated so that they all lead to total catches of 95,000 t. The scenarios are shown as the lower three rows in the text table below (rounded to nearest 100 t).

CATCH OPTIONS IN DIV.IIIA WITH DIFFERENT PROPORTIONS TAKEN IN SD 22- 24 AND SUBAREA IV	TAC DIVIIIA NSAS+WBSS		CHES +WBSS		CHES BSS	CATCHES WBSS	CATCHESTOTAL WBSS	CATCHES NSAS	CATCHES NSAS + WBSS

^a Derived from short term predictions

The bottom shaded row in the above text table (scenario 6), shows the combined TAC for the C- and D-fleets that should be set to remain at predicted total WBSS catches for 2006 at 95,000 t, assuming the present share of the total WBSS herring taken outside Divisiion IIIa (i.e. 64% of WBSS taken in SD 22-24 and IVa East in 2004).

Exploring a range of total WBSS catches

Considering the present high level of the NSAS stock, catch options were explored for the two stocks in Division IIIa at total catches set for the WBSS stock. The settings for scenario 6 above (64% of WBSS taken in SD 22-24 and Subarea IV in 2004), were expanded with different total catches of the WBSS stock. Further the 2004 compositions of NSAS and WBSS in each of the C and D fleets were employed (in Division IIIa).

The text table below gives examples of catch options for the C- and D- fleets at different TACs for the entire WBSS stock between 60,000 and 100,000 t (values rounded to the nearest 100 t). The shaded row in table below corresponds to scenario 6 in table above.

^b Total TAC for DivIIIa as in 2005

^c Backcalculated from short-term predictions of WBSS catch of 2006 (95,000 t)

^d when a fixed TAC in SD22-24 is used a fixed amount of 7,000t in Subarea IV is assumed

	MANAGEMENT C	ONSIDERATIONS I	FOR DIVIIIA BASED O	N SHORT TERM PRE	DICTIONS (2006)	
Western Baltic	Spring Spawn	ers	North Sea Autu	mn Spawners	Both Stocks together		
All fleets total catches	Fleet C (22% of TAC)	Fleet D (15% of TAC)	Fleet C (WBSS/56%)	Fleet D (WBSS/51%)	Fleet C	Fleet D	
60,000	13,100	8,700	10,500	8,400	23,600	17,100	
65,000	14,200	9,500	11,400	9,100	25,600	18,600	
70,000	15,300	10,200	12,200	9,800	27,500	20,000	
75,000	16,400	10,900	13,100	10,500	29,500	21,400	
80,000	17,500	11,600	14,000	11,200	31,500	22,800	
85,000	18,600	12,400	14,900	11,900	33,500	24,300	
90,000	19,700	13,100	15,700	12,600	35,400	25,700	
95,000	20,800	13,800	16,600	13,300	37,400	27,100	
100,000	21,900	14,500	17,500	14,000	39,400	28,500	

For a TAC on catch of NSAS and total catch by the fleets in Division IIIa to be compatible with the advise for WBSS, the numbers derived as above, based on the largest advisable catch of WBSS, are upper bounds on the advisable catches of NSAS by the C- and D- fleets. Thus the resulting catch options were also used as constraints for short term predictions for the NSAS herring (section 2.7).

Consequences of continuing the present transfer of quota from C-fleet to A-fleet

The working group has treated this problem as effectively a partial transfer between fleets, but also to some extent a transfer between stocks, since the C-fleet exploits both North Sea autumn spawners (NSAS) and Western Baltic spring spawners (WBSS).

To calculate possible effects of the present quota transfer, the proportions of the two stocks for the last year, 2004, were used. The text table below shows the percentage of WBSS 2004 catches in two stocks in Division IIIa.

WBSS	FLEET C	FLEET D
2004	0.56	0.51

Thus, one t of C-fleet total quota can be assumed to represent 0.56 t of catch of WBSS. A transfer of one t from the C-fleet to the A-fleet would then imply that the catch of WBSS by the C-fleet is reduced by this amount, while the catch by the A-fleet is increased by a little less than one t, since part of the A-fleet catches are taken in the Eastern part of Subarea IV where they are a mix of NSAS and WBSS herring. Further complications are the previously mentioned misreporting by areas.

The effect of a transfer of 50% of Norwegian catches amounting to 6,400 t and will at the most equal a reduction in outtake of 3,600 t in the exploitation of WBSS, since part of the catches will anyway be taken in the transfer area where WBSS are taken in the 2nd and 3rd quarter. The changes in F and SSB for WBSS will thus be marginal.

Conclusions

- a. The presently set TAC for Division IIIa of 96,000 t in the C-fleet is too high for a sustainable fishery, with the present share taken in SD22-24 and Subarea IV.
- b. A TAC of 37,400 t for the C-fleet is in accordance with F_{sq} predictions of 95,000 t WBSS total, under assumptions of retained catch share among areas and retained proportions among stocks. For the SD 22-24 estimated catches will be 51,600 t, and the WBSS taken in Subarea IV will amount to 8,800 t.

c. Low recruitment of the three most recent NSAS year classes together with an increase in the WBSS stock, is expected to lead to changes in stock composition as well as area distribution and thereby affect near future catch options. Especially consequences for the D-fleet catch options should be closely followed.

Proportions as % are calculated using combined otolith microstructure data from Danish and Swedish catches in 2004.

Age-classes with few analyses were joined into plus-groups with more than 11 individuals and indicated by numbers in italics. In the source column the constructed plus groups are indicated.

In the source column the constructed plus groups are indicated. For 0-ringers in Q3 the proportion from the Acoustic survey in Kattegat was used.

4 CELTIC SEA AND DIVISION VIII HERRING

Introduction

The herring fisheries to the south of Ireland in the Celtic Sea and in Division VIIj exploit autumn and winter spawning components. For the purpose of stock assessment and management, these areas have been combined since 1982. The management unit covers all of Divisions VIIg,h,j and k and the southern part of Division VIIa (Figure 1.5.1). In the recent seasons, Ireland has been almost the only country to exploit the stock.

4.1 The Fishery in 2004-2005

4.1.1 Advice and management applicable to 2004 - 2005

The TAC in 2004, was 13,000 t. In 2004, ICES considered the status of this stock to be uncertain. ACFM advised that catch restrictions in 2005 should be 60% of the average catches in 1997 –2000 corresponding to catches of less than 11,000 t. This was expected to allow SSB to increase. B_{pa} is set at 44,000 t and B_{lim} at 26,000 t. F reference points are not defined for this stock. The TAC is set by calendar year, whilst the assessment of the stock is conducted on a seasonal basis (1st April to 31st March).

The fishing season runs from the 1st April 2003 to the 31st March 2004, though the fishery was traditionally only opened on the 1st October. In the current and previous seasons, the fishery was allowed to remain open throughout. This was to allow vessels to target fish outside the spawning seasons when the fish are of better quality and marketability. The spawning box closures implemented under EU legislation continued. Box A was closed in the 2003-2004 season and Box B was closed in November 2004 (Fig 4.1.1.1). In 2005, Box C will be closed. In addition to these, Box A was voluntarily closed in the recent seasons, being finally reopened in December 2003. This initiative was put in place by the Irish Southwest Pelagic Management Committee to afford extra protection to first time spawners. Areas mentioned in the text are shown in Figure 4.1.1.2.

The Irish Southwest Pelagic Management Committee was established to manage the Irish fishery for this herring stock. This committee, therefore, has responsibility for management of the entire fishery for this stock at present. The committee has the following objectives:

- To build the stock to a level whereby it can sustain annual catches of around 20,000 t.
- In the event of the stock falling below the level at which these catches can be sustained the Committee will take appropriate rebuilding measures.
- To introduce measures to prevent landings of small and juvenile herring including closed areas, and or appropriate time closures.
- To ensure that all landings of herring should contain at least 50% of individual fish above 23 cm.
- To maintain and if necessary expand, the spawning box closures in time and area
- To ensure that adequate scientific resources are available to assess the state of the stock
- To participate in the collection of data and to play an active part in the stock assessment procedure.

Ireland has 86.4% of the quota with, France and the Netherlands having most of the remainder. The Irish quota in 2004 was 11,236 t. This is managed by allocating individual quotas to vessels on a weekly basis. Participation in the fishery is restricted to licensed vessels. The licensing requirements have been changed. Previously, vessels had to participate in the fish-

ery each year to maintain their licence. Now this requirement has been lifted. This has been one of the contributing factors to the reduction in number of vessels participating in the fishery in recent seasons. Fishing is restricted to the period Monday to Friday each week, and vessels must apply a week in advance before they are allowed to fish in the following week.

4.1.2 The fishery in 2004/2005

In recent years, this fishery has been prosecuted entirely by Ireland. The landings in this fishery since 1958 are shown in Figure 4.1.2.1. The fishing season is the same as the assessment period, 1st April to the 31st March the following year. The fishery closed in the last week of January in 2005.

Fishing in 2004 began in the first week of August on offshore marks around the Kinsale Gas Field and the Labadie Bank. Traditionally these offshore fish have been of a superior size and condition to those caught on the inshore roe fisheries. Between August and the start of the traditional roe fishery in October, approximately 3,900 t were landed. Fish were described as being easily located and more available than in the previous two years of this fishery. Participation in the offshore third quarter fishery was limited to those vessels with refrigerated seawater tanks (RSW).

In November fishing switched to the inshore roe and fillet fishery off the Waterford Coast. Fishing was described by fishermen as the best in many years in terms of the early arrival of the fish on the grounds, the size of the fish, and enhanced availability with the result that the annual quota was exhausted by the first week in December. Large aggregations of distinctly smaller fish were reported from the inner harbour and these encouraged the entry of small local dry hold boats to the fishery. In the roe fisheries most of the quota is caught in the first part of the week suggesting that the dense spawning aggregations scatter with the application of effort and re-aggregate as fishing intensity dies down later in the week.

Fishing resumed in January 2005 with the allocation of a quota of 4,000 t which was exhausted by the end of the month. In the latter half of January fishermen reported that the size of fish decreased in VIIa south with the result that the larger RSW component of the fleet, comprising eight vessels moved their effort to the Cork coast at Ballycotton in VIIg where fish of a good size were found to be consistently available. Fishermen report that good catches in this ground maintaining their fishery through the two year box closure brought in by the South West Pelagic Management Committee in 2000 to rest the fishing grounds in VIIa south. In recent years a pot fishery for shrimp has developed in this area and this has curtailed to some extent access to this ground.

Throughout the season occasional catches were made other coastal grounds, mainly in sheltered areas in response to bad weather. The most important of these in the 2004/2005 season were Kinsale and Courtmacsherry harbours in VIIg where approximately 600 t were caught in the third and fourth quarters. A consistent theme in discussion of Irish herring fisheries with fishermen is that the different fishing grounds are characterized by distinctive "stocks" of fish. With respect to Kinsale and Courtmacsherry these components are described as harbour herring, i.e. herrings of small size and inferior condition.

One traditional ground that did not fish well in the 2004/2005 season was the area outside Cork Harbour at the Daunt Rock. Fish were registered here during the acoustic survey but not caught.

Landings from VIIj, traditionally concentrated between Valentia Island and Loop Head, declined in the assessment period and this was attributed to the enhanced availability of fish in VIIg and VIIa south and further north in VII B where increased availability of fish was also reported. VIIj lies between these grounds and the home ports of the RSW component of the

Celtic sea herring fleet and the landings that were reported are described by fishermen as incidental catches made on the way, or returning from the main fishing grounds.

Total landings for the assessment period were about 12,700t. Figure 4.1.1.2. shows the division of catches by statistical rectangle and quarter for the period. As in previous years markets for fillets were adversely affected by the North Sea and Atlanto-Scandian herring fisheries, that have flooded markets in recent years. Landings with roe of suitable quality returned the most value to fishermen.

4.1.3 The catches in 2004/2005

The estimated national catches from 1988–2004 for the combined areas by year and by season (1 April–31 March) are given in Table 4.1.3.1 and Table 4.1.3.2 respectively. The total catches for the fishery over the longer period from 1958 to 2004 are shown in Figure 4.1.3.1 The catch, taken during the 2004/2005 season was about 12,700 t having increased from around 11,000 t during the previous season.

Discards

There are no estimates of discards for this fishery. Anecdotal reports from fishermen suggest that discarding is not a feature of this fishery at present.

4.2 Biological Composition of the Catch

4.2.1 Catches in numbers-at-age

Catch numbers at age are available for the period 1958/1959 to 2004/2005. These data include discards, when estimates were available (until 1997). In 2004/2005, 10% of the catch was composed of 2 ringers compared with 41% in 2003/2004. In 2004/2005, 3-ringers comprise 50% of the catch with 4 and 5 ringers comprising 24% and 9% respectively. This represents a considerable shift towards older fish in the catches from the previous season with little indication of any follow through from younger fish (Table 4.2.1.1). In all 85% of the catch were 3 ringers or older. In 2003/2004 the slightly increased proportion of older fish was explained at least in part by the summer fishery that caught large fish in VIIg and VIIj. The further proportional increase of older fish in 2004/2005 is thought to be due to the steep decline in 2 ringers in the catches. Only in VIIj quarter 4 and to a lesser extent VIIg quarter 4, was the proportion of 2-ringers above 25%. In all other metiers the proportion does not exceed 10% of the catch (Figure 4.2.1.1 and Table 4.2.1.1).

In 2001, VIIa south was voluntarily closed and reopened in early December 2003. Since reopening, catches from this area have been dominated by the 2000/2001 year class. In the current season, 85% of the catches were 3-ring fish or older. This may indicate that the box closure of VIIa south in 2001 was successful as a conservation measure. The 2000/2001 year class dominates the catches in the entire fishery. However the weakness of following year classes is a cause for concern and is the salient feature of the catches for 2004/2005. In 2003/2004 landings from the offshore third quarter fishery were distinguished by the elevated numbers of larger and older fish relative to the inshore roe and fillet fisheries.

In in 2004/2005, 2-ringers were the dominant year class in VIIj, in contrast to the rest of the assessment area. A difference in mean weight at age was also found for herring in this area, in contrast to VIIa south and VIIg indicating that this area may be more similar to VIIb than to the Celtic Sea (Table 4.2.1.2). These differences were noted previously, and it was recommended that the western part of VIIj be removed from this assessment area and combined with VIaS and VIIbc.

4.2.2 Movements of juvenile fish

A recent study on herring otolith microstructure has elucidated several points with respect to the natal origin of juvenile herring in the Irish and Celtic Seas (Brophy and Danilowicz, 2002). The results show that fish spawned in the eastern Celtic Sea are present as larvae in the Irish Sea, where fish of local origin are also found. The fish of Celtic Sea origin then return to that area as 1- and 2-ringers.

Brophy and Danilowicz, (2002) found Celtic Sea herring to have different growth rates depending on whether they resided in nursery areas in the Celtic Sea, the western or eastern Irish Sea. The variability in growth rate patterns occurred mainly in the larval phase and could be attributed to the different temperature regimes of the Celtic and the Irish Seas, suggesting that larval drift into the Irish Sea could be a factor in Celtic Sea recruitment variability. Larval dispersal can further influence maturity at age. In the Celtic Sea faster growing individuals mature in their second year (1 w. ring) while slower growing ones spawn for the first time in their third year (2 w. winter ring). Pre-recruitment dispersal such as into the Irish Sea and subsequent decrease in growth rates could thus determine whether juveniles are recruited to the adult population in the second or third year (Brophy and Danilowicz, 2003).

4.2.3 Quality of catch and biological data

Since 1997 there has been a major increase in the monitoring of landings from this fishery and the management measures were again tightly enforced throughout the season. As a result the accuracy of the landing figures are thought to be considerably better for this period.

Biological sampling of the catches throughout the region were guided by daily appraisals of the fishery supplied by members of the Irish Southwest Pelagic Management Committee, including fisheries officers, fishermen, skippers and processors (Table 4.2.3.1). Due to the close proximity of the working group to the end of the fishing season, in the first quarter of 2005 it was not possible to process samples in time for the assessment for VIIg. Under the DCR the sampling of this stock is relatively good.

4.3 Fishery Independent Information

4.3.1 Acoustic Surveys

Acoustic surveys of this stock have been carried out since 1990, with the exception of 1997. Up until 1996, two acoustic surveys were carried out. In 1997 there was no research vessel available to do the survey. Since 1998, usually only one winter survey was conducted (Table 4.3.1.1). The survey conducted in 2004/2005, was conducted on the Celtic Explorer, for the first time. The abundance estimates produced are presented in Table 4.3.1.2).

The acoustic survey of the 2004/2005 season was carried out in November and December of 2004 (O'Donnell et al. WD, 2005). This single survey was aimed at pre-spawners as they move inshore to spawn. The survey track was begun at the northern boundary of VIIj, and moved south and then eastwards, ending in VIIaS (Figure 4.3.1.1a). The only substantial echo traces of herring were encountered in the bays and inlets of VIIj (Figure 4.3.1.1b). Offshore in VIIg, herring were encountered in a mix with sprat. An acoustic trace registered at the Daunt Rock outside Cork Harbour was not fished but was allocated to herring. In the Baginbun Bay area (eastern VIIaS) herring were encountered close inshore. The survey design of parallel transects, did not allow for the inclusion of these echo traces in the overall survey estimate, because they were located on the inshore inter transect. It was concluded from this information that the survey underestimated the stock size in these areas in 2004/2005.

The commercial fishery was closed in early December, so it is not possible to compare the sparcity of herring echo traces in the main fishing zone (eastern VIIg and in VIIaS) to the ex-

perience of fishermen. However, when the fishery was reopened in January 2005, about 4,000 t of herring were caught in these areas. In the previous season (2003/3004), the geographical positioning of the Sa values obtained along the southwest and south coasts closely matched that of the pattern of fleet activity.

The age compositions of the survey abundance estimate and the commercial catch numbers at age were dissimilar in the 2004/2005 season. In the commercial fishery all metiers displayed a dominance of 3- and 4-ringers, with the exception of VIIj in the 4th quarter (Figure 4.2.1.1). The acoustic abundance estimate was dominated by 2- and 3-ringers, closely mirroring the VIIj fourth quarter fishery only (Figure 4.3.1.2).

The age structured index of biomass and catch numbers from acoustic surveys in this area, is shown in Table 4.3.1.2. The overall biomass estimate (13,000 t) is considerably lower than in the previous season (89,000 t). This is certainly an underestimate of the stock size in the area at this time, and is not a good indicator of abundance in the 2004/2005 season. However, the results of the survey are not inconsistent with the low abundance of 2-ringers in the commercial catches.

The working group estimated the biomass of the herring aggregations in Baginbun Bay, that were not included in the survey estimate. This was accomplished by Kriging the abundance estimate obtained on the inshore intertransects in this area, using the Surfer package. Using the target strength, length weight relationship and same settings as used in the production of the survey estimate, an estimate of 1,500 t was obtained. This suggests that the survey did miss some fish that were present in the area at the time. However, the abundance of these fish was not of sufficient quantity to merit their addition in the survey estimate.

4.3.2 Other surveys

An investigation of the utility of the Irish segment of the western IBTS survey was made (Johnston and Clarke, WD 2005). Gear changes were thought to have accounted for the higher catches in the 2004 survey. Ageing of herring on this survey only began in 2003. It is considered that this survey will be very useful as a recruit index in three years or so, when a time series is achieved. In the meantime the following survey data should be made available to the group as a matter of urgency:

- DARD Groundfish Survey of the Irish Sea, Northern Ireland
- CEFAS Celtic Sea Groundfish Survey, UK, England and Wales.
- EVHOE Groundfish Survey of the Celtic Sea, France.

4.4 Mean weights and maturity-at-age

The mean weights in the catch for this stock over time are presented in Figure 4.4.1. There has been an overall downward trend in mean weights at age since the mid-1980's. The values for 2003/2004 among the lowest in the series. This trend in mean weights at age is similar to those seen in the Irish Sea and to a lesser extent, the North Sea.

For the past two seasons substantial catches were taken outside the spawning season. The spawning season is considered to begin on the 1st October and progresses through to mid February, in a generally west to east direction. For 2003/2004, the mean weights in the stock were calculated from samples taken in VIIg, VIIj and VIIaS from October 2003 to February 2004. Summer samples, and samples from Waterford Harbour were not used in these calculations.

While the maturity-at-age for this stock (Figure 4.4.2) has been assumed to be constant throughout the whole time period (50% of 1 ring fish are assumed to be mature at age 1 and

100% mature at 2 ring), in comparison with other stocks it may not be stable and should now be updated.

4.5 Recruitment

At present there are no recruitment estimates for this stock that can be used for predictive purposes. The 2003 recruitment was estimated as weak in the 2004 assessments, and appears to be the weakest in the series. There is little information in the assessment on the strength of recruitment in 2004, because these 1-ringers are poorly represented in the catches.

In this stock a proportion of juvenile fish are present in the Irish Sea and do not recruit to the Celtic Sea and Division VIIj until they are mature. Therefore neither the numbers of 1-ringers in the stock as estimated from the acoustic surveys nor the numbers in the catches give a reliable indication of year class strength. The relationship between the numbers of 1-ringers taken per hour in the Northern Irish ground fish surveys in the Irish Sea and the numbers of 1-ringers estimated by ICA for the Celtic Sea and Division VIIj was examined in a working document presented to the 1999 WG (Armstrong et al., 1999) and the results suggest that these surveys may become a useful indicator of recruitment to the Celtic Sea and Division VIIj when a longer time-series is established.

4.6 Stock Assessment

4.6.1 Preliminary data exploration

Recent WG's have used the results of the acoustic surveys in the ICA programme but stated that the results should be taken as minimum estimates. In 1998 the WG decided to use the age-disaggregated data but only over the 2 to 5-ringers as a relative index in the ICA programme, and this has been continued. As in the 2004 assessment, this year's assessments used a different proportion of F before spawning (=0.551 in 2004 and 2005) and the different procedure for estimating stock weights (see 4.4.4).

Catch numbers at age from 1958 to 2004 are presented in Figure 4.6.1.1. These numbers were mean standardised and show a pattern of truncation of older ages in the catches during the mid-1970's to the early 1980's. This coincided with impaired recruitment and high fishing mortality, leading to stock collapse. Some stronger year classes restored the stock in the early 1980's. In recent seasons there is evidence of lack of older fish and recent year classes seem to have lower survivorship. The dominance of 3 and 4 ringers in the past two seasons is also apparent.

Catch curves of each individual year class since 1958/1959 are presented in Figure 4.6.1.2. The declining limb of these catch curves can be considered as an indication of total mortality on those year classes, assuming constant catchability. There is a trend towards higher total mortalities for the year classes in the 1970's and 1990's, and lower rates during the 1960's and 1980's. These trends are more apparent with reference to Figure 4.6.1.3, which shows catch curves for several year classes combined.

Log catch ratios ($\ln C_{a,y}/C_{a+1,y+1}$) are presented in Figure 4.6.1.4 and smoothed by 4 year running average in Figure 4.6.1.5. Data for 1-ringers are noisy, because these ages are not fully selected in the fishery. The data for older fish are noisy, particular in later years, reflecting their relative weakness in the catches in recent years. There is a marked trend in log catch ratios. Since 1998/1999 the values have displayed an increasing trend. This may reflect increased mortality. It may also indicate a change in fishing pattern, as landings have decreased over this period.

Catch curves of individual year classes based on the abundance estimates from the acoustic survey are presented in Figure 4.6.1.6 and for several year classes combined in Figure 4.6.1.7.

There is evidence from these data that total mortality has increased on year classes since 1997. Catchability is likely to have changed in the survey series since 1996, the last year that uniform design was used (Tabe 4.3.1.1). The mortality signal produced by the acoustic survey is greater for the recent year classes, than the signal from the commercial data. This may indicate that catch data are poorly underestimated in some years, or that catchability is different in each series. This may also be explained by different catchabilities of the older ages in the fishery, over the time period. It most likely also reflects the discarding of fish in the past. There is less information in the most recent years in these data, because they refer to year classes.

The changes in this fishery in recent seasons have been documented in last year's report. The working group considered that the inability of the assessment model to track changes in the exploitation pattern and the inconsistencies between the survey and the fishery could not be overcome. The working group considers that this stock cannot be assessed using the ICA model as has been done in the past. A particular problem in 2004/2005 has been the acoustic survey. It is considered to underestimate the stock abundance, because of fish being located further inshore than the vessel could cover and because aggregations with strongly contagious distributions were located in these area.

Due to the problems outlined above, it was decided to explore the ICA model using the same procedure as last year, with the 2004/2005 catch and survey data included. Two scenarios were explored:

- 2005a Same procedure as last year with updated catch and survey data
- 2005b Same procedure as last year with updated catch, but not survey data.

The results of the ICA run using the same procedure as last year, with the new catch and survey data are presented in Figures 4.6.1.8 to 4.6.1.12 and Table 4.6.1. The results of the ICA run using the same procedure as last year, with the new catch but excluding the 2004 survey data are presented in Figures 4.6.1.13 to 4.6.1.21 and Table 4.6.2. Comparisons of these two exploratory assessments, along with last year's estimates are presented in Figure 4.6.1.20. A table is given below showing the options used in the assessment since 1998.

Working Group	Age structured acoustic Index (ages 2-5 rings)	Shrinkage	Separable period	
1998	1990-1996	No	1992-1997	
1999	1990-1996, 1998	No	1993-1998	
2000	1990-1996, 1998	Yes (5yr)	1994-1999	
2001	1990-1996, 1998, 2000	No	1995-2000	
2002	1990-1996, 1998, 2000-2001	No	1996-2001	
2003	1990-1996, 1998-2002	No	1998-2003	
2004	1990-1996, 1998-2003	No	1997-2003	
2005a	1990-1996 and 1998-2004	No	1998-2004	
2005b	1990-1996 and 1998-2003	No	1998-2004	

Following the procedure of HAWG in 2003, recruitment in the final year was replaced with geometric mean 1958-2001. The estimates from both exploratory runs are very different with regard to SSB and F. A clear result of both runs is that recruitment in 2003 was at a historically low level. The current observations of this recruitment are considered more reliable than those obtained in 2004.

Exploratory run 2005a displayed very imprecise fit, with poor minimisation (Figure 4.6.1.8). There were high year residuals in recent years and string negative trends in age redisuals for 4-ringers and older. Catchabilities were reasonably estimated. However, the estimate of F in the final year was condidered to be unfeasibly high (Figure 4.6.1.20).

Exploratory run 2005b displayed more precise model fit with a better resolution of the minimisation routine. Ther residuals were lower, though they still displayed a trend. F in the final year was lower than in 2003. Overall the model was more stable, but the working group did not consider it acceptable either (Figure 4.6.1.20).

Due to the incoming 1-ringers being 50% mature, SSB in 2004 was recalculated as:

 Σ N₂₀₀₄ * Stock weight at age₂₀₀₄ * Proportion mature at age₂₀₀₄

SSB has declined since the mid 1990's, in both runs. This downward trend accompanies a decline in the mean weights in the catch (Figure 4.4.1). Including the 2004 acoustic survey produces an estimate of SSB that is declining and below B_{lim} . Excluding the 2004 acoustic survey produces an SSB estimate that is fluctuating around B_{pa} . Uncertainty in the estimates of SSB are presented in Figure 4.6.1.21 (note logarithmic scale). There was huge uncertainty in the estimate of SSB in the late 1990s' especially the 1998 and 1999 estimates. It is clear that the uncertainty has reduced somewhat in recent years, and this may reflect the improved reporting of catches that has taken place in this period, or a strong year effect in the survey.

Including the 2004 acoustic survey produces an unfeasibly high value for mean fishing mortality in 2004, a much higher estimate than in any previous assessment. Excluding the 2004 survey estimates mean F in the range of time series. Very high estimates of F are sometimes a feature of this assessment, when recruitment has been weak. The weak representation of recruits in the modelled population is manifested as an increase in F. This can be considered an artefact of the ICA model formulation as applied to this stock.

The results of these exploratory runs display the sensitivity of the model to the inclusion of the 2004 acoustic survey. The working group felt that both model formulations resulted in poor model fit and unacceptable residual patterns. Consequently, neither was accepted as an assessment of stock status. Instead it was thought necessary to highlight the important information that is known about the stock. There is a lack of older fish in the catches and modelled populations. Fishing mortality has declined since the late 1990's, concomitant with decreased landings. SSB has declined in this period and though there have been some relatively strong year classes, recruitment in this period has been below average strength.

There is a marked absence of 2-ringers in catches, highlighting a recruitment failure of the 2001/2002 year class. There is no evidence from the acoustic survey to contradict this finding. Therefore this pattern in recruitment should be considered relevant. The poor performance of the acoustic survey has been well described. Whether it is excluded, the main signal is the same, that recruitment in 2003 has been very weak. In a fishery that is based on only a few age classes, this is a cause for concern.

4.6.2 Results of the assessment

No final assessment was presented in 2005. The analyses presented in Section 4.6.1, above, are useful as an indicator of trends in the stock development. However, they are not useful for determining SSB or F in the final year.

4.6.3 Comments on the assessment

No final assessment was conducted in 2005.

4.7 Short-term projection

In the absence of an agreed assessment, it was not considered informative to conduct any short term predictions. This is a departure from the routine procedure. However, the changes in the exploitation of the stock have meant that no assessment is informative enough to form the basis of deterministic short-term predictions.

4.8 Medium term projections

Though no final assessment was conducted by the working group in 2005, some exploratory medium term projections were carried out. In particular it was considered relevant to evaluate the current management objective, of building the stock to a level that could produce yields of 20,000 t per year. Simulations were carried out to evaluate the risk of the stock falling below Precautionary Approach reference points, at various levels of TAC. This was accomplished using the FSSSPS, as described in the ICES Study Group on Management Strategies, 2005. This procedure can be considered as a simple hindcast, projecting forward from 2001. The results of these simulations should be treated with caution as the software has not been fully tested as yet. The simulations are based on the trial assessment presented in Table 4.6.1.2, using 2001 as the start point and projecting forward to the end of 2007. The working group landings estimates were set as the yields in the intermediate years. The stock characteristics are such that there is great variation in the system, particularly in recruitment. Recruitment was modelled using a Ricker curve with stochasticity added, based on the CV's from the normal distribution. The input data are described in the text table below. This projection is a preliminary approach to this issue and further development will be conducted in the coming months.

Recruitment Geometric mean 1958 to 2001
Stock recruit relationship Ricker with stochasticity from normal distribution
Catch weights 1-9+ ringers, 2001
Stock weights 1-9+ ringers, 2001
Catches WG estimates up to 2004/2005
M 1-9+ ringers, 2001
F 1-9+ ringers, 2001
Prop. F before spawning 0.2

Figure 4.8.1 shows a projection of the level of SSB at the end of 2007 under a variety of TAC's. The simulation suggests that the system is very noisy, with large 95% confidence limits. The results suggest that even with low TAC's, there is a risk that the stock will collapse. A large proportion of the catch is made up of the incoming year class. If recruitment fails, there is a high probability of stock collapse, under a constant TAC, even if set at a low level. This effect is highlighted in Figure 4.8.2, which shows the probability of the stock being below Precautionary reference points at the end of 2007. Even with zero catch there is a 25% probability of being below B_{pa} (=44,000 t) at end of 2007. These simulations though preliminary in nature, do highlight the danger in having a fixed TAC over a long period. It would seem appropriate to develop a Harvest Control Rule that would limit fishing when recruitment is weak, or at low SSB levels. The sensitivity of such a harvest control rule needs to be evaluated, by way of simulations.

The working group also conducted preliminary evaluations of the stated management objective of changing the exploitation pattern of the fishery. In recent seasons, the management committee and Irish authorities allocated a portion of the quota for fishing in the summer. This change in the selection pattern has adversely effected the assessment. Managers considered that catching the quota in summer would result in lower fishing mortality, because less fish per tonne would be caught. Preliminary yield per recruit analyses were conducted, based on the 2005 exploratory assessment. Further work on this subject will be conducted intersessionally, and presented by the HAWG to ACFM at its May meeting.

4.9 Quality of assessment

The landings in this fishery have been monitored rigorously and management measures tightly enforced, resulting in considerably better accuracy in landings figures. Allied to this there is a comprehensive sampling programme of the landings that has been enhanced through cooperation with the industry. Sampling in this stock continues to be very high for some years and is described in Section 4.2.3. A difficulty arose in processing sufficient samples for VIIg in the first quarter of 2005. This is because this working group takes place in close proximity to the end of the fishery season.

Fishery independent data are provided by the autumn acoustic survey, of which the principle index is the age dis-aggregated numbers. These data are noisy, and therefore the index only uses the mid range of the year cases. There are no estimates of recruitment. In 2004, the survey was considered to be an underestimate of the stock abundance, because fish were distributed inshore, and could not be included in the survey. It is considered by HAWG that alternatives to the current winter survey be explored. This may include conducting the acoustic survey during the feeding period, when fish are more homogeneously distributed offshore.

In 2005, two exploratory assessments were produced, both following the same procedure as last year. The only difference being the inclusion of the 2004/2005 acoustic survey. No final assessment was accepted by the working group, and therefore no short term predictions were carried out.

The group considers that the survey series as currently used in tuning is problematic. In particular, the earlier surveys before 1996 are not comparable with most of those since 1998. This is because in the earlier period, two surveys were conduced each season (Table 4.3.1.1), whilst since 2001, only one pre-spawners survey was conducted. It may be useful to explore the use of only those surveys since 2001 in tuning, in next year's assessment.

The present exploratory assessments is essentially an update on the previous year's assessment, with or without the 2004 acoustic estimate. In recent years, the assessment has become unstable due to problems with acoustic survey numbers at age data and an apparent change in the recruitment levels between 1996 and 1998, which was not detected by the assessments in those years. The uncertainty in the assessment around the mid to late 1990s (partially due to differences in the trends in the acoustic survey and catch data) is reflected in the historical uncertainties (see Figure 4.6.2.23). The group suggests that efforts be made to describe the reasons for this great uncertainty in the assessment over that period.

4.10 Biological reference points

Biological reference points were discussed in detail in the 2000 WG report (ICES 2000/ACFM:10) and in the report of the previous years (ICES 1999/ACFM:12, ICES 1998/ACFM:14). A summary of this discussion was presented in the 2003 HAWG report. \mathbf{B}_{pa} is currently at 44,000t and \mathbf{B}_{lim} at 26,000 t for this stock \mathbf{F}_{pa} and \mathbf{F}_{lim} are not defined. The SGPRP (ICES 2003 ACFM:15) has reviewed the methodology for the calculation of biological reference points, and applying a segmented regression to the stock and recruit data from the 2002 HAWG assessment gave a breakpoint at 61,306 t. This change point appears to be very high with respect to the historical exploitation of the stock. Given that there is a cluster of observations just above this value the sensitivity of the method to these data needs to be further investigated. The HAWG decided that the first priority for this stock should be to achieve a stable assessment and that once this was done the reference points would be reinvestigated (see section 1.4.2). There is still considerable instability in the assessment, so there is no basis for a revision of reference points at this point.

4.11 Management considerations

The current management of this fishery has been described above. The working group encourages the initiatives of the Irish South West Pelagic Management Committee. The group considers that efforts continue and be intensified. In particular, efforts to maintain the good quality of fishery dependent data should continue. A stock that is subject to such variations requires good quality data. The state of the stock is still uncertain, there is no strong evidence that it is recovering, and there is evidence of the weakness of an incoming year class.

No final assessment was conducted in 2005, because of the uncertainties in the basic data. Trial assessments were used to track the trends in the stock development, but give less information on current status. Nevertheless the weakness of the 2001/2002 year class is a cause for concern. This is because the fishery is based on few year classes, and a failure of an incoming cohort could quickly lead to stock decline.

The current assessment procedure is no longer applicable to this stock. Consequently, the cycle of conducting annual VPA assessments, conducting short term predictions and producing annual TAC advice is flawed. The fishery is recruitment driven, and as such has more in common with sardine and anchovy stocks than to any other herring stock in Europe. The distinguishing properties of the fish in this stock include their early age at maturity, the few year classes present and the fluctuations in recruitment.

The working group considers that this stock should be managed using a harvest control rule, that allows managers to react quickly to the fluctuations in the stock. This rule needs to be developed in consultation with stakeholders and scientists. However such a rule should be developed rapidly. Preliminary medium term projections were conducted for this stock in 2005. These projections highlight the danger in having a fixed TAC, that is unreactive to the stock dynamics. This analysis was used by the working group to evaluate the current management plan, though this evaluation was preliminary.

Box Closure

It is difficult to evaluate the effects of closing this box between 2001 and December 2003. However the strongest year class to enter the fishery in recent years was that of 2000/2001. This cohort was strongly dominant in catches from this box, once it was opened in 2003 and dominated catches throughout the Celtic Sea (though not VIIj) in 2004/2005. The box closure must have reduced F on this cohort. The subsequent 2001/2002 year class is estimated to be very weak. This cohort should be fully selected by now. Each recruiting year class is of great importance to the stock composition. Therefore every effort should be made to protect incoming cohorts.

Ability of the stock to produce annual catches of 20,000 t.

It is clear that at present the stock cannot sustain catches at this level. The preliminary simulations conducted by the HAWG suggest that this stock is not suited to having annual TAC's set at a constant level, without a string rule to reduce catches when necessary.

Prevent landings of small and juvenile fish

It would appear that catching the quota during the summer would result in lower fishing mortality, with fewer fish per tonne of landings. However in order to evaluate if the summer fishing strategy is beneficial to the stock it is necessary to consider the effect of removing biomass before spawning, as well as the trade off between growth and mortality. The yield per recruit analyses conducted by the HAWG are preliminary in nature, and further work is required.

The present state of this stock is uncertain. However all available information points to the weakness of the incoming 2001/2002-year class. This fishery is dominated by recruitment;

therefore the failure of an incoming cohort is a cause for concern. ICES advice in the past two years has been for catches not greater than 11,000 t (= 60% of catches in the period 1997-2000). The failure of the incoming year class indicates that advised catches for 2006 should be lower than 11,000 t. The working group notes that the TAC in the past two years has been set at a higher level than that advised by ICES. HAWG considers that this TAC should not be in excess of ICES advice.

Table 4.1.3.1 Celtic Sea and Division VIIh, j and k herring landings by calendar year (t), 1988–2004. (Data provided by Working Group members.) These figures may not in all cases correspond to the official statistics and cannot be used for management purposes.

^{*}November survey only, likely to be an underestimate of stock size.

Additional fish located inshore during the 2004/2005 survey, not included in estimate.

^{**} Poor survey coverage due to bad weather, likely to be an underestimate. This survey is not included in assessment.

Table 4.6.1. Celtic Sea & Division VIIj herring. Results of trial assessment, using the same procedure as last year, with updated catch and 2004 survey data.

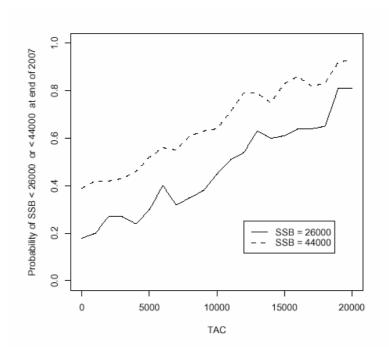

Figure 4.8.2. Celtic Sea and VIIj herring. Results of preliminary stock projection using FSSSPS. Probability that SSB at the end of 2007 being below Precautionary Approach reference points. $B_{pa}=44,\!000$ t and $B_{lim}=26,\!000$ t.

5 West of Scotland Herring

5.1 Division VIa (North) Advice and Fishery

5.1.1 ACFM Advice Applicable to 2004 and 2005

ACFM reported in 2004 that based on the most recent estimates of SSB, ICES classified the stock as having full reproductive capacity. The assessment showed a relatively stable SSB over the last three years, substantially higher than the previous ten years. Fishing mortality has stabilised at a low level. The 1998, 1999 and 2000 year classes are abundant. Current fishing mortality is at a level where the stock remains within PA bounds. Consequently, ACFM recommended that fishing mortality be maintained at *status quo* (=0.19), corresponding to catches in 2005 of 30,000 t.

The agreed TAC for 2005 is 30,100 t. The TAC in 2004 was 30,000 t.

There are no explicit management objectives for this stock. A \mathbf{B}_{lim} of 50,000 t has been agreed by ACFM for this stock.

5.1.2 The VIa (North) Fishery

Historically, catches have been taken from this area by three fisheries.

- A Scottish domestic pair trawl fleet and the Northern Irish fleet operated in shallower, coastal areas, principally fishing in the Minches and around the Island of Barra in the south; younger herring are found in these areas. This fleet has reduced in recent years.
- ii. The Scottish single boat trawl and purse seine fleets, with refrigerated seawater tanks, targeting herring mostly in the northern North Sea, but also operated in the northern part of VIa (N). This fleet now operates mostly with trawls but many vessels can deploy either gear.
- iii. An international freezer-trawler fishery has historically operated in deeper water near the shelf edge where older fish are distributed. These vessels are mostly registered in the Netherlands, Germany, France and England but most are Dutch owned.

In recent years the catch of these last two fleets has become more similar and has been dominated by younger adults resulting from increased recruitment into the stock.

In 2004, the Scottish trawl fleet fished both in areas similar to the freezer trawler fishery, and in the coastal areas in the southern part of VIa (N), unlike the previous year where the Scottish fleet tended to omit these costal areas.

As a result of perceived problems of area misreporting of catch from IVa into VIa (N), Scotland introduced a fishery regulation in 1997 with the aim to improve reporting accuracy. Under this regulation, Scottish vessels fishing for herring were required to hold a license either to fish in the North Sea or in the west of Scotland area (VIa (N)). Only one licensed option could be held at any one time. However in 2004, the requirement to carry only a single licence was rescinded. Area misreporting of catch taken in area IVa into area VIa (N) seems to have increased. In addition some herring caught during the 4th quarter mackerel fishery in VIa (N) was area misreported as IIa herring, presumably because the VIa (N) quota had been exhausted. It is possible that the relaxation of this single area licence has contributed to a resurgence in area misreporting. Reinstating this single area licence requirement should be considered as it appears to be helpful to management for this area.

5.1.3 Catches in 2004 and Allocation of Catches to Area for VIa (North)

In the past, fishery-independent information confirmed that large catches were being reported from areas with low abundances of fish, and informal information from the fishery and from other sources confirmed that most catches of fish recorded between 4°W and 5°W were most probably misreported North Sea catches. The WG considered that the serious problems with misreporting of catches from this stock, with many examples of vessels operating and landing herring catches distant from VIa (N) but reporting catches from that area, had been reducing in recent years, from some 30,000 t to around 5,000 t in 2002 and none reported in 2003, but there appears to be an increase in 2004, with over 6,000 t being area misreported (see section 5.1.2). The problem was detailed in the Herring Assessment WG report in 2002 (ICES 2002/ACFM:12). Reallocation information was obtained from only some of the fleets.

For 2004, the preliminary report of official catches corresponding to the VIa (N) herring stock unit total 29,854 t, compared with the TAC of 30,000 t. The Working Group's estimates of area misreported catches are 6,762 t. An additional 123 t of herring has been reported as discarded. At such a low level currently, discarding is not perceived to be a problem.

The Working Group's best estimate of removals from the stock in 2004 is 23,092 t. Details of estimated national catches from 1983 to 2004 are given in Table 5.1.1.

5.2 Biological Composition of Commercial Catches in VIa(North)

Age composition data, by country and by quarter, are detailed in Table 5.2.1. The number of samples used to allocate an age-distribution for the VIa (N) catches has steadily decreased from 52 in 2002, 37 in 2003 down to 10 in 2004. This is due to two problems;

- i. the difficulty of targeting sampling on vessels that fish in this area because these vessels fish in other herring areas and there may be no prior knowledge of the fishing intentions of the vessel before departure from port.
- ii. the area misreporting recorded of catch taken in other in other areas and reported as VIa (N) can result in successfully collected samples being subsequently reallocated correctly to their true area thus loosing numbers of samples from the sampling program, see sections 5.1.2 and 5.1.3.

Samples were obtained from the Scottish and Netherlands fleets, these were used to allocate a mean age-structure (weighted by the sampled catch) to unsampled catches, in the same quarter, or in adjacent quarters if no samples were available in the corresponding quarter. If no sampling data were available for a quarter, a mean age-structure of all samples from adjacent quarters was used. The allocation of age structures to unsampled catches, and the calculation of total international catch-at-age and mean weight-at-age in the catches were made using the 'sallocl' programme (Patterson, 1998). While only a limited number of samples were obtained, these did come from the major fisheries by fleet area and season and are thought to be representative of the catches.

Catch in number-at-age information is given in Table 5.2.2. Several large yearclasses can be seen clearly at age 2 and older in the catch at age table; the 1995 yearclass age 8 in 2004 and the 1988 yearclass age 5 in 2004. No catch at age 1 ring was seen in any of the samples this year. Age 1 ring herring in the catch are variable and are rarely representative of yearclass strength and are down-weighted in the assessment, see section 5.6

In the past concern has been raised over the quality of sampling of commercial catch. It was suggested in the 2001 ACFM technical minutes that an analysis of catch by quarter and country might shed some light on the variability in the catch information. In practice the fishery is often dominated by a single quarter catch, and a single country dominates sampling. Thus such an analysis is impossible. In 2002 the Working Group conducted an extensive analysis

of the sensitivity of the assessment to missing catch information (Section 5.1.12 in ICES 2002/ACFM:12). Although sampling is relatively poor the analysis indicated that sampling for age information was not the major source of variability in the assessment at that stage.

5.3 Fishery-independent Information in VIa(North)

5.3.1 Acoustic Survey

The 2003 acoustic survey was carried out from 6-25 July using a chartered commercial fishing vessel (MFV *Enterprise*). The total biomass estimate obtained was lower than in the previous year (396,000 t this year compared to 739,200 t in 2003 and 548,800 t in 2002), and is the similar to the 2001 value. Biomass estimated from the acoustic survey tends to be noisy and similar fluctuations have been observed in previous years. The distribution was generally more northerly than in previous years and while herring were found in areas similar to those in 2003, namely south of the Hebrides off Barra Head, west of the Hebrides and along the shelf edge the greater abundance was found in the North. Further details are available in the Report of the Planning Group for Herring Surveys (ICES 2005/G:04). Estimates of abundance by age and in aggregate spawning stock biomass for 2003 and for previous years are given in Table 5.3.1. The same large yearclasses seen in the catch can be seen clearly at age 2 and older in the acoustic survey table; the 1995 yearclass age 8 in 2004 and the 1988 yearclass age 5 in 2004.

5.4 Mean Weight-at-age and Maturity-at-age VIa(North)

5.4.1 Mean Weight-at-age

Weights-at-age in the catches and weights-at-age in the stock from acoustic surveys are given in Table 5.4.1. The weights-at-age in the stock appear to be near or at the long term low. This contrasts with last years weights which were only slightly lower than the long-term mean across the rest of the age range. It's unclear from the data if this is a trend or just measurement error. Further investigations of mean weights from this area is required for the future.

5.4.2 Maturity Ogive

The maturity ogive is obtained from the acoustic survey and collated in Table 5.4.2 for the period 1992 to 2004.

In 2004, maturity for age 2 wr herring is higher than in 2003. This is in contrast to the mean weights at age, which are lower. In the North Sea there is some evidence for a direct relationship between proportion mature at age and growth. This type of relationship is currently not seen in the data for VIa (N).

5.5 Recruitment VIa(North)

There are no specific recruitment indices for this stock. Although both catch and acoustic survey have catches-at-age 1-ring both the fishery and survey encounter this age only incidentally. The first reliable appearance of a cohort appears at 2-ring in both the catch and the stock. Thus in predictions, estimates of both 1- and 2-ring herring numbers from the assessment need to be replaced for prediction years.

5.6 Stock Assessment Vla(North)

5.6.1 Data Exploration and Preliminary Modelling

As last year, an exploratory assessment of the stock was carried out by fitting an integrated catch-at-age model (ICA version 1.4w described in the methods section in the 2003 Working

Group report (ICES 2003/ACFM:17, Section 1.6.1)). An age-structured index was available from the acoustic survey from 1987, 1991-1996 and 1998-2004 (Section 5.3.1).

In 2004 a selection pattern of 8 years 1996-2003 was used, this length of period was found to be sufficiently long to smooth out noise in the data. ICA was then run for the available timeseries, 1957-2004, to compare the model fit for this year with the 2004 working Group assessment.

The residual patterns for the two runs are very similar (Figure 5.6.1). The magnitude and location of residuals shown in the bubble plots are consistent and the year residuals follow the same pattern shifted by one year. The age residuals are more different, with a relatively larger value for 4-ringers this year. However, the age residuals values are small and there are no trends with age.

The selection pattern for the 2005assessment is essentially identical to the two previous years (Figure 5.6.2). It was concluded that as ACFM recommended an update assessment was appropriate for this stock.

5.6.2 Stock Assessment

This is an update assessment using the same settings as in 2004, with the 8 year separable period moved forward one year from 1995-2003 to 1996 to 2004.

Assessment of the stock was carried out by fitting an integrated catch-at-age model (ICA version 1.4w). The model settings are the same as for 2003 and 2004. The run log for the assessment is shown in Table 5.6.1. The catch and survey data were down-weighted for 1-ring herring (see the 2001 Working Group assessment report (ICES 2001/ACFM:12)). The input data are given in Tables 5.6.2 to 5.6.8. The output data are given in Tables 5.6.9 to 5.6.18. The assessment results in an SSB for 2004 of 124,000 t and a mean fishing mortality (3-6 ringers) of 0.17 (Table 5.6.14). The model diagnostics (Tables 5.6.13 to 5.6.18 and Figures 5.6.3 to 5.6.14) show that the total residuals by age and year between the catch and the separable model are reasonably trend-free and small. The acoustic survey age and year residuals patterns are trend-free. The acoustic survey residuals are of similar magnitude to the catch model residuals but show more evidence of year effects. This year's estimate of SSB in 2003 (155,000 t) shows a small decrease in biomass from last year's estimate (162,000 t). The large 1998 yearclass is still seen as a peak in numbers of 5-ringers in 2004 in the assessment the catch and acoustic survey data. The 2000 year class is abundant as 3-ringers in the acoustic survey. The 2001 yearclass is seen to be small in both the survey and the catch data. Initial indications of the 2002 yearclass are that it is not small, but the data available to estimate this is rather poor.

The assessment is consistent with last year assessment and shows a drop in SSB, though the stock is still substantially higher than during the period 1997 to 2000. Fishing mortality has stabilised at a low level.

Figure 5.6.15 shows the trajectories of 5, 25, 50, 75 and 95 percentiles from the estimates of historical uncertainty of F, SSB and recruits produced in the final assessment. These are based on 1000 bootstrapped samples of residuals. Uncertainty in the 2004 Working Group assessment is comparable to that in the 2003 Working Group assessment. In 2003 uncertainty was found to be considerably reduced from previous years (ICES 2003/ACFM:17), reflecting the stability of the input data over the final two or three years to that date. The greatest uncertainty in F is in 1997/98 when catch data were poorly sampled due to area misreporting. This year area misreporting has increased again, see section 5.2. and only 10 samples of catch at age were obtained, suggesting that the catch might be poorly evaluated. However, the stability of the selection pattern seen in the assessment suggests that the poor sampling may not have

had a bad affect on the assessment. Figure 5.6.16 shows the same uncertainty data for the terminal year plotted as F against SSB.

5.7 Harvest Control rule options for the management of VIa (north) herring

The review and development of medium term management options for VIa herring has been carried out following the structure contained in the SGMAS report (ICES 2005). The review concentrates on management options for medium term exploitation of herring in this area and considers in detail the implications of the productivity of the stock, or more explicitly the possible range of stock relationships and their influence on management choices.

A.a Broad objectives

There are no explicit management objectives for this stock but the implied objectives are to obtain maximum stable yield within the precautionary approach.

A.b Operational Objectives

The operational objectives are to keep the stock above B_{lim} , which is currently estimated to be 50,000 t (see section 5.8). Yield requirements include consideration of year-to-year stability and maximising long term yield.

B. Conformity of a HCR to the management strategy

The stock is currently managed with a TAC. It is thought that this type of management, backed up with enforcement is applicable for this fishery.

An HCR with an F target and year on year restrictions on changing TAC would therefore be an appropriate choice of HCR.

The current assessment provides a reasonable basis for evaluation of an HCR.

The stock was depleted in the 70s and has never recovered to the SSB seen in the 1960s. The stock recruit relationship observed in recent years may be different from the one describing the full time-series. For management there is a need to consider if there is a requirement to allow the possibility that the stock will recover to biomass levels seen in the 60s. If this option is selected as a management objective, this will then require selection of a long term F that will allow this to happen. In this context an explicit biomass target for the stock may not be appropriate because the biomass levels seen in the early 60s may be unachievable. In addition to this criteria, management should be based on currently observed levels of recruitment and annual growth.

TAC implementation and management control in for this stock is variable, the main problem is area misreporting of catch in such a way that catches have often been less that the TAC and rarely more. Discarding in the herring fishery is low through some discarding of herring may occur in the mackerel fishery in the same area and there may be some high grading in the freezer trawler fleets.

C. HCR simulation parameterisation

C.a Biological operating model

The simulation was carried out using STPR3 and S3S (Skagen 2004) as a simulation program. The chosen model consists of three stages.

1. Depleted stage with fixed F (F1) less than or equal to intermediate F for biomass below Blim of 50,000 t.

- 2. Intermediate stage with a fixed intermediate F (F2) when the biomass is above Blim but below Btrig (B2)
- 3. Long term stage long term F (F3) above a biomass trigger (B2)

This may collapsed to two stages if F1 and F2 are equal (combining stages 2 and 3). The rule may be modified with an option of a year on year constraint on the change in TAC.

C.a.a Selection of Stock / Recruitment relationship.

Data on the state of stock is available from 1957 to 2004, the recruitment in the last 4 years is still uncertain so has been omitted from the study. The stock experienced heavy fishing in the 1960's and the fishery was closed in 1979 / 1980. The SSB during the period 1957 to 1975 is greater in every year than the SSB during the subsequent period 1976 to 2000. This could be due to a number of possibilities

- reduced productivity in the area,
- the average fishing mortality at mean F = 0.35 is too high to allow recovery.
- The stock depletion removed some important component of the stock.
- Area closure of 50% of the spawning grounds may have caused excess pressure on the remaining 50%

The stock (SSB) and recruitment data are plotted together with fitted models for the period 1976 onwards and for the complete period in Figures 5.7.1 and 5.7.2 respectively. The parameters of the fitted stock recruit relationships are given in Table 5.7.1.

Within each data period, the different models (Figures 5.7.1 and 5.7.2) do not give major differences in perception of the stock. Though there are considerable differences between the stock recruit relationships depending on whether the whole period is considered to be representative of the current situation (statistically / biological stationarity) or if the recent period is regarded as different. The model that fits best in both periods is the Shepherd, as the AIC value is lowest in both cases, implying the increase of parameters is helpful in functionally describing the observed recruitment data. In addition to the low Akaike Information Criteria (AIC) the pattern of residuals around the Shepherd model is perhaps slightly better behaved than for the other models (see Figure 5.7.3 and 5.7.4) but the difference is small. There is however, a biological problem with concluding that the Shepherd reflects the truncated series correctly as this implies reduced recruitment at higher biomass. We know from the longer time-series that increased recruitment at higher biomass has been observed. In order to model the short time period both Shepherd and Change Point models have been used in management exploration. The latter model is preferred as it gives recruitment that does not decrease at higher biomass, and may thus be regarded as compromise option between the Shepherd model for long and truncated data series.

For the simulated recruitment Figures 5.7.5 to 5.7.7 show the comparison of the simulated probability density functions (pdfs) expressed as a cumulative probability distributions and observed recruitment. In all three cases the simulated pdfs area a reasonable representation of the observed recruitment.

C.a.b Natural mortality;

Natural mortality used in the assessment is taken from the assessment of North Sea herring, the adjacent area. This is based on MSVPA run for the North Sea. (Table 5.6.5)

C.a.c Growth;

Growth is obtained as observed weights at age from annual acoustic surveys of the area and is available as individual estimates of growth for each year since 1991and is used as a stochastic variable in the simulation, taking each year as a single set of observations. (Table 5.6.4)

C.a.d Maturity;

Maturity is obtained from annual acoustic surveys of the area and is available as individual estimates of fraction adult for each year since 1991and is used as a stochastic variable in the simulation, taking each year as a single set of observations. (Table 5.6.6).

Maturity and weights at age are selected as an annual set from the same year in the stochastic simulations. So while cohort dependent growth is not fully simulated correlations between weight at age an maturity are included in the simulation.

C.a.e Other issues:

There are no other major issues included in the simulation. There are no major multi-species interactions. There has been some limited spatial restrictions with a spawning area closure, however, it has not been possible to show any benefit to the stock and the extent to which this restriction has actually been operational is unknown. There are no density or growth dependent effects observed with this stock. With the exception of weights and maturities all the variables are treated as independent without correlation or auto-correlation.

C.b The fishery

The fishery is a mostly a directed pelagic trawling fishery which is currently dominated by two fleets of trawlers. There is occasional discard or slippage of herring and limited high grading. Some herring are caught as a by-catch within a seasonal mackerel fishery and either landed or discarded depending on availability of quota. Some of the VIa north herring quota is taken in adjacent areas and misreported as VIa north herring. This aspect has been limited by the use of single area licence restrictions. This was relaxed last year but continuation of this measure is thought to be helpful and is under consideration. The selection pattern for the fishery has been stable for the last 3 years (Figure 5.6.2) and is taken from the ICA assessment (Table 5.6.15).

C.c Representation of the knowledge and decision process in the simulation

The general error levels in measurement and implementation bias and variability are included. However, not all the elements for management are fully included, for example there is no feedback between implementation and implementation error.

C.c.a Observation error on biological parameters

Observation error on growth and maturity is included and characterised as part of the stochastic variability seen in the observed data.

C.c.b Assessment error

Assessment as a source of observation error is implemented as SD of 30% and a bias of 10%, these values are very slightly larger than the observed values taken from the ICES quality control sheets for the period 1995 to 2003.

C.c.c Advice and decision making.

No systematic implementation error is included in the simulation, although there is some evidence for over-reporting of catch due to area-misreporting. However, including systematic under utilisation of quota that cannot be guaranteed into the future is not thought to be applicable. In 2003 implementation of regulations seemed to be reasonably effective, and last years deterioration may have been due to relaxation of regulations. To model some level of implementation error a 10% stochastic variable is used for implementation to reflect the uncertainty in implementation. This may slightly exceed observed variability but may be used to account for some area misreporting.

D Management measures

Management measures currently consist of, a TAC regime and a spawning seasonal closure covering approximately 50% of the spawning area. As this is a largely directed pelagic fishery with a only a small amount of discarding and by-catch a TAC is an appropriate method of setting limits for catch. Only the TAC is simulated.

E The robustness of the management evaluation

The current assessment method is ICA tuned with a single acoustic survey. The assessment is rather noisy, and precision and bias in the assessment has been taken into account in two ways.

- i. The current state of the stock is used as a starting point using variance covariance matrix obtained from ICA. As indicated above the historic time-series of assessments suggests that a precision of 30% is appropriate.
- ii. The method has been checked for sensitivity to the precision of the estimation by using other error levels (20% and 40%) and although, the level of risk is sensitive to this no major differences occur.

Sensitivity of the HCR to assessment bias has been examined by using different values, the current bias of 10% slightly over estimates the values observed from about 8 years ago. The assessment bias was more severe in the earlier years (1994-1997) but has been less severe after this (1998-2000). It is possible that the stability of the bias is dependent on stock and regulations applied but there is insufficient data to establish this.

Sensitivity to management failure is considered through examination of recent implementation. Current management is through a role-over TAC and there has been little change in recent years. Implementation failure has been associated with under shooting the TAC through area misreporting rather than over exploitation. Any undeclared landings that are occurring are not included in the data and the simulations assume these will be stable. There are area restrictions due to a spawning season closure but they may not be fully effective and the stock has shown no signs of benefiting from the closure. Stock productivity was higher before the closure was implemented.

F Results

The sensitivity of the HCR to the S/R relationship is the critical aspect of management for this area. Figure 5.7.8, 5.7.9 and 5.7.10 summarise the range of possible yield and risk for different values of long term F from 0.2 to 0.6. Included in this set of evaluations is a full range of values of intermediate and depleted F (F1 and F2), trigger biomass (B2) and year on year constraint on TAC. The colour of the symbol indicates the risk of SSB falling below Blim. Risk is dealt with in 5 classes, 0-1%, 1-2.5%, 2.5-5%, 5 to 10% and >10% risk if SSB falling below Blim at least once in the 10 years of the simulation. For clarity the strategies with risk less than 5% are shown separately in the lower panel of each figure. It is not intended that these plots are examined in detail, it is the broad areas of colour that indicate the main possibilities.

The maximum achievable median yield for each long term F (F3) with a risk less than 5% are given separately for each stock recruit relationship in Figure 5.7.11 to show how the different stock recruitment relationships affect the results. The difference between the two models for the truncated period (1976 to 2000) is small, it is difficult to say which of these models is correct, though there is a small statistical preference for selecting the Shepherd model over the change-point model. However, the Shepherd model implies reduced recruitment at an SSB 150,000 t. This is in contrast to the longer time-series which gives a model delivering elevated recruitment at these SSBs. The Change Point model which gives no reduction in recruitment at higher biomass is therefore preferred though not on statistical grounds.

The implications for management of the long series is illustrated in two ways.

- i. Figure 5.7.12 illustrates that all three S/R models explain the current state of the stock quite well. Using historic exploitation: at F=0.355 with a standard deviation of 0.248. This conforms to the observed conditions for the last 30 years. As can be seen from this figure exploitation in this way delivers a stock at a level close the current SSB. This supports the view that the current state of the stock does not preclude the longer series model being appropriate.
- ii. The development of median yield and SSB and median recruitment and SSB are shown in figure 5.7.13a and b respectively for different values of long term F from 0.2 to 0.4. From this it can be seen that the most probable direction for the development of the stock depends on whether F long term is above or below 0.35

The value of long term F 0.35, which is to be used as guidance, should not be regarded as a precise value that can be used as an exact management target but rather as a general indication of where this change in exploitation occurs.

Example Selection of HCR.

- 1) Potential increase in biomass and yield from a large stock is to be allowed. F long term selected as 3.0 or below. Table 4.7.2 indicates that F=0.3 gives rather low potential increase, a reduction of F to 0.25 gives approximately 1,000 t reduction in catch but a much higher potential increase in SSB. A further reduction to F=0.2 with 2,000 t reduction seems to great. So long term F is chosen to be F=0.25. Some reduction is required in the even for stock decline so F2 is selected as F=0.2
- 2) Figure 5.7.2 panel b illustrates the trade off between yield, year-on-year given the choice from (1) above F3 = 0.25 an F2=0.2. The risk of SSB falling below Blim in the options illustrated in this panel is always under 1% so all options may be judged precautionary. Maximum yield is seen to occur at two locations on the panel, at
 - a. B2 = 75,000 t and catch constraint (CC) of 1,000 t.
 - b. B2 = 120,000 t and CC = 2,000 t.

At first sight this may seem unusual that there are two maxima, but point (b) occurs with the HCR often giving SSB in stage 2 of the rule and thus F=0.2 where as point (a) is mostly in stage 3. If minimum year-on-year change in TAC is an objective then point (a) gives the maximum yield. Point (a) seems to be the best solution. The chosen HCR becomes:-

F=0.25	if SSB $> 0.75,000 \text{ t}$ year.	TAC changes by less than 1000 t each
F=0.2	if SSB < 0.75,000t	No constraint on TAC.

G Conclusions

There is one major management option to be considered first. Should management choose a strategy that has some reasonable probability for the stock to expand to the levels observed in the 70s? Exploitation at an F of over 0.35 is thought to have a higher probability of keeping the stock at its current lower level or causing it to decline. Exploitation at F 0.3 or lower is thought have an increased probability of allowing expansion of the stock. So exploitation below this level at say F = 0.25 is recommended if it is considered important to allow the stock to increase. If for biological reasons expansion of the stock is currently not possible then this choice of F < 0.3 delivers a yield that is a little reduced from the maximum. Reduction of F below 0.25 would probably produce even lower yields.

Having already selected the long term F (F3) Figure 5.7.14 illustrated the choice among other parameters in the HCR. These panels show yield, risk, and the range in change in TAC for different values of B trigger (B2) and year on year constraint on change in TAC. This figure needs to be considered only after the decision to exploit above or below F=0.35 has already been taken. The main features of these options are summarised in Table 5.7.2 The Following text box contains an evaluation of the choice of HCR parameter for panel a in Figure 5.7.2.

The WG considers that these simulations provide a good basis for managers to decide on the basic form of a HCR for VIa (N) herring. However, experience with the North Sea suggest that rules that use constraints on year-on-year change in TAC need more detailed evaluation than is provided here. In particular the influence of correlation in recruitment should be investigated further. Managers can use this study to decide on the main elements of the HCR they require such as the most suitable long term F. If there is a wish to have a year-on-year constraint on change in the TAC then the chosen scenario can be evaluated in more detail to ensure it is robust.

H Additional information

The study carried out here has examined assessment precision from 20% to 40% and bias of 0, 10% and 20%, though the results shown here are only for 30% precision and 10% bias. In these simulations implementation error was constrained to be within a 10% SD. Currently the TAC is often not fully taken but should management fail to keep catches in line with the TAC, this suggested HCR may need to be re-examined.

Natural Mortality has been assumed to be known and stable.

Recruitment simulations do not include significant autocorrelation, excluding that resulting from the relationship it's self.

The choices here depend very much on a rather uncertain S/R relationship. Research on the validity of this relationship would be helpful. If the stock continues to provide reduced recruitment at SSBs above 120,000 t the S/R relationship and HCR should be re-evaluated.

Its is suggested that the situation should be reviewed approximately every 5 years.

5.8 Projections

5.8.1 Deterministic short-term projections

Two scenarios for deterministic short-term projections are presented: *status quo* F for 2005 and TAC constraint for 2005. The status quo option is consistent with both the current fishery which did not take the TAC in 2004.

Short-term projections were carried out using MFDP. Input data are stock numbers on 1st January in 2005 from the 2005 ICA assessment (Section 5.6, Table 5.6.11), with geometric mean replacing recruitment at 1- and 2-ring in 2005 and 1-ring in 2004. The retrospective assessment of recruitment in the 2003 Working Group (ICES 2003/ACFM:17) showed the substantial revision of 1- and 2-ring herring abundance in subsequent assessments, justifying the use of geometric means for these ages. The selection pattern used is as estimated by ICA (Table 5.6.13). For the projections, data for maturity, natural mortality, mean weights-at-age in the catch and in the stock are means of the three previous years (i.e., 2002 - 2004) (Table 5.8.1.1). Two examples have been run F *status quo* and a second option with TAC constraint. The results of short-term projection is shown in the text table below, illustrating that at *status quo* F catches can be expected to be stable at around 25,000 t.

SCENARIO	2005	2006	2007
1 – status quo F	$F_{2005} = F_{2004} = 0.19$	$F_{2006} = F_{2004} = 0.19$	$F_{2007} = F_{2004} = 0.19$
	Status quo F	Status quo F	Status quo F
	Catch = $25,057 \text{ t}$	Catch = $26,417 \text{ t}$	Catch = 25,988 t
			SSB = 148,000 t
TAC Constraint	$F_{2005} = 0.2271$	$F_{2005} = F_{2003} = 0.19$	$F_{2006} = F_{2003} = 0.19$
	TAC	Status quo F	Status quo F
	Catch = $30,100 \text{ t}$	Catch = $25,600 \text{ t}$	Catch = $25,382 \text{ t}$
			SSB = 145,000 t

The results of the F *status quo* short-term projections can be seen in Tables 5.8.1.2 - 5.8.1.3. Table 5.8.1.2 shows single option predictions for 2006 and 2007. Table 5.8.1.3 shows the multiple options for 2006. SSB rises from approximately 137,000 t in 2005 to 148,000 t in 2007. The results of the TAC constraint for 2005 short-term projections can be seen in Tables 5.8.1.4 - 5.8.1.4. SSB rises from approximately 133,000 t in 2005 to 145,000 t in 2007.

5.8.2 Yield-per-recruit

A yield-per-recruit analysis was carried out using MFYPR to provide a yield-per-recruit plot for VIa (N) (Figure 5.8.2.1) the values for $\mathbf{F}_{0.1}$ and \mathbf{F}_{med} are 0.16 and 0.27 respectively. These may be compared with the current F (2004 assessment) of 0.19.

5.8.3 Stochastic medium-term projections

Four sets of medium-term projections were carried out on the basis of four selected HCRs evaluated in section 5.7. The main settings are summarised in the table below.

	LONG TERM F (F3)	INTERMEDIATE F (F2)	DEPLETED F (F1)	TRIGGER BIOMASS (B2)	YEAR-ON-YEAR TAC CONSTRAINT
Scenario 1	0.2	0.2	0.2	Not relevant	2,000 t
Scenario 2	0.25	0.2	0.2	75,000	1,000
Scenario 3	0.3	0.25	0.2	120,000	1,000
Scenario 4	0.35	0.25	0.2	105,000	2,000

The method for simulation used is the same as the method described in Section 5.7. The starting numbers in 2005 are taken from the last column of Table 5.6.11 substituting arithmetic mean recruitment at age 1 (1.021 million) and age 2 (388,200) obtained from the period 1976 to 2002. Arithmetic mean values are used here in preference to geometric means used in the short term predictions because the arithmetic mean combined with the stochastic variability gives the correct projections. Weights-at-age catch (Table 5.6.3), and the stock (Table 5.6.4) and maturity at age (Table 5.6.6) were taken stochastically from the observed values from 1991 onwards. Natural Mortality was taken as fixed (Table 5.6.5). The stock-recruit relationship used in the medium-term projection was the Change Point option with simulated recruitment as shown in Figure 5.7.5.

The results of the stochastic medium-term projection are given in Figure 5.8.3.1-4. Scenarios 1 and 2 give a rise in SSB to levels where the stock might expand further if the conditions match those seen in the 1950s and 60s. Scenario 3 shows a small decline and Scenario 4 shows a decline in SSB to levels where further expansion is unlikely

5.9 Reference Points

Only the Blim (at 50,000 t) is defined and agreed reference point for VIa (N) herring. Previously some difficulties were encountered obtaining plausible Flim, Bpa and Fpa values for this stock. The use of HCR simulations presented in Section 5.7 only requires the definition of Blim. The reference point table from ACFM report May 2004 is given below for information.

Reference points – Precautionary Approach points defined in 2004

B _{lim} is considered to be defined at 50 000 t	B _{pa} was proposed as 75 000 t
F _{lim} not defined	F not defined

5.10 Quality of the assessment

The 2002 and 2003 Working Groups inspected a number of possible sources of model uncertainty, including sensitivity to choice of length of separable period and sensitivity to a small number of isolated large cohort estimates in the acoustic survey. They suggested that despite the large noise in the signals, the assessment was consistent and credible, although the choice of the length of the separable period was an important consideration in maintaining consistency. There appears to be much greater stability in the assessment compared to 5-7 years ago and the assumptions used in the ICA model are credible and consistent with the information given in the catch and biological data.

In the late 1990s there was concern about the retrospective error in the assessment, in particular sensitivity to poor sampling of catch. For the 2005 assessment the number of samples used to allocate an age-distribution for the VIa (N) catches has decreased from 52 in 2002 to 10 in 2004. Although this is a rather small number of samples they came from the major fisheries by fleet area and season and are thought to be representative of the catches. This is confirmed by the similarity in selection pattern and residual pattern seen in this years assessment and compared with last years (see section 5.6). Whereas the assessments in current years appears to be more stable, a low level of sampling in coming years could result in problems with the consistency of the model in the near future.

Under- or overestimation of the catches due to area misreporting implies bias on the estimation of stock status, since the stock size is estimated using these catches. Misreporting decreased from 30,000t the mid 1990s to 5,000t in 2002, while in 2003 it was estimated to be effectively zero. However during 2004 area misreporting seems to have increased to 6,000t, possibly to relaxation in the area licence requirements, increasing uncertainty.

Retrospective analyses of the assessment from 2004 to 2000 were carried out. Figure 5.9.1 shows the recruitment, SSB and mean F_{3-6} from ICA assessments, with an 8 year separable period for assessments in 2001 to 2004 and a 7 year separable period in 2000. The retrospective analyses show similar patterns in recruitment from 2002 onwards, but more variable estimates in the years before this period. Estimates of SSB are variable, while estimates of mean F_{3-6} are rather stable.

Analysis of the analytical retrospective for each cohort (Figure 5.9.2) generally showed stability of information once cohorts are full recruited to the fishery at age 4. In some years the estimated fish abundance from some of the smaller cohorts is unstable (1997, 1999, 2001 year-classes), particularly for 1- and 2-ringers. The larger cohorts (1995, 1998 and 2000 year-classes) are estimated more reliably. The 1-ringers are down-weighted in the assessment and the 1- and 2-ringer estimates are not used in the projections (where geometric mean values are used). The retrospective analysis indicates that the problems (raised over the last few years) in estimating catch-at-age in both 1997 and 1998 are now causing little influence to the current assessment.

Generally while this is a noisy assessment, it is sufficiently accurate to confirm the conclusions that the SSB is well above Blim and fishing mortality is low and the assessment provides a suitable basis for the management of the stock and for the HCR evaluation.

5.11 Clyde herring

5.11.1 Advice and management applicable to 2004 and 2005

Management of herring in the Clyde is complicated by the presence of two stocks that are not separated currently; a resident spring-spawning population and the immigrant autumn-spawning component. Management strategies have been directed towards rebuilding the highly depleted spring-spawning component to historical levels.

The measures which remain in force in order to protect the indigenous spring-spawning stock are:

- A complete ban on herring fishing from 1 January to 30 April;
- A complete ban on all forms of active fishing from 1 February to 1 April, on the Ballantrae Bank spawning grounds, to protect the demersal spawn and prevent disturbance of the spawning shoals;
- A ban on herring fishing between 00:00 Saturday morning and 24:00 Sunday night;
- The TACs in 2004 and 2005 were maintained at the same level as in recent years (1,000 tonnes).

5.11.2 The fishery in 2004

Annual landings from 1955 to 2004 are presented in Table 5.10.1. There were no landings recorded in 2004. Along with a reduction in the fishery the number of samples from the fishery have been reduced in recent years (Table 5.10.2), with no fishery this year no samples were collected for Clyde herring in 2004.

5.11.3 Weight-at-age and stock composition

The catch in numbers-at-age for the period 1970 to 2004 is given in Table 5.10.3. Weights-at-age are given in Table 5.10.4. Mean weights in the stock have not been available from research vessel surveys since 1991, therefore the weights in the stock used are the weights-at-age in the catches.

5.11.4 Fishery-independent information

There were no surveys carried out in 2004. Historical estimates from these surveys are tabulated in (ICES 1995/ACFM:13).

5.11.5 Stock Assessment

The structure of the stock in the Clyde remains uncertain. No survey data are available from recent years therefore no assessment could be attempted.

5.11.6 Stock and catch projections

In the absence of an analytical assessment no stock projections can be provided.

5.12 Management Considerations

5.12.1 VIa (N) Management Considerations

In the 1990s management of this stock was complicated by area misreporting from area IVa in particular. Due to changes in the fishery and some management changes (in particular Vessel Monitoring Systems –VMS- and single area licenses) area misreporting into VIa (N) has declined from a high of 30,000t in the mid 1990s to 5000 t in 2002. It was estimated at effectively zero in 2003 but has risen again in 2004 to 6,000 t. However, this followed relaxation of

single area licensing. It is considered that any measures that ensure TACs are taken correctly in the area will improve management.

The assessment presented here is more certain than those from the mid-1990s due to the improvements in the quality of the catch-at-age input data and the longer time-series for the acoustic survey. Current F_{3-6} is thought to be below 0.2 and SSB at 125,000 t is well above the suggested \mathbf{B}_{lim} of 50,000 t. Figure 5.6.15 indicates that SSB than F_{3-6} are similarly uncertain but that this assessment provides a sound basis for assuming that the stock is currently lightly exploited and able to sustain the current fishery. The yield-per-recruit indicates that a fishery at the same or slightly higher level is sustainable the medium-term. Harvest Control Rule simulations provided in section 5.7 give a range of management options, summarised in Table 5.7.2 and figure 5.7.14. Projections (Figure 5.8.3.1-4) are provided to illustrate yield and stock under assumptions of Change Point Stock recruitment. For this stock it is important to remember that F > 0.35 gives low probability of stock moving to higher biomass and if the is desired by managers an F below this level is required. In the short term F = 0.25 (34,500 t) in 2006 compatible with a rising SSB and sustainable in the medium term.

The WG considers that this assessment, while noisy, is sufficiently accurate to confirm the conclusions that the SSB is well above Blim and fishing mortality is low and that it provides a suitable basis for the management of the stock. The WG also considers that the HCR simulations provide a good basis for managers to decide on the basic form of a HCR for VIa (N) herring. However, experience with the North Sea suggest that rules that use constraints on year-on-year change in TAC need more detailed evaluation than is provided here. If managers can use this study to decide on the main elements of the HCR they require such as the most suitable long term F then the chosen scenario can be evaluated in more detail for year-year change.

5.12.2 Clyde herring Management Considerations

In the absence of surveys and catches, nothing is currently known about the state of the spring-spawning stock. All the management measures, currently in force, need to remain. TACs should remain at the current low level until more is known about the dynamics of this stock.

          Enter estimates of the extent to which errors
          in the age-structured indices are correlated
          across ages. This can be in the range 0 (independence)
          to 1 (correlated errors).
Enter value for FLT01: West Scotland Summer Acoustic Sur-->
                                                                        1.0000000000000000
           Do you want to shrink the final fishing mortality (Y/N) ?-->N
          Seeking solution. Please wait.
          Aged index weights

Gamma				4.62E-01				2.63		
AIC	82.04	79.37	78.46	74.40	32.13	30.07	31.39	28.22		

^{*} This model was biologically implausible for the data and was therefore not used in the evaluation.

Table 5.7.2. Herring in VIa (N) summary of general outcomes for different options of long term exploitation F from 0.2 to 0.4. Showing a small range of harvest options, effect on SSB if the long period S/R relationship holds, and yield options under the short term period S/R relationship. For more details of the latter see figure 5.7.14.

F3	F2	Stock Recruit		Stock Recruit period 1976-2000						
(Long term)	(intermediate)	period 1957- 2000	Range of Median Yield	B2 (B trigger)	Year on Year Constraint	Risk (falling below Blim)				
0.2	0.2	Median SSB increases by approx. 95 % over 10 year period	37,300t unless stock increases	Not relevant	Highest yield at 2000 t constraint	0				
0.25	0.2	Median SSB increases by approx. 44 % over 10 year period	38,400 to 39,400t unless stock increases	Max yield at 75,000t	Lowest yield at 4000 t Highest at 1000 t constraint	Less than 1%				
0.3	0.25	Median SSB almost stable	39,300 to 40,800t	Max yield at 120,000t	Lowest yield at 4000 t+, Highest at 1000 t constraint	Less than 1%				
0.35	0.25	Median SSB decreases by approx. 18 % over 10 year period	40,100 to 41,600t	Max yield at 105,000t	Lowest yield at 6000 t+, Highest at 2000 t constraint	0.7% to 1.6%				
0.4	0.25	Median SSB decreases by approx. 35 % over 10 year period	33,400 to 43,000t	Max yield at 95,000t	Lowest yield at 6000 t, Highest at 2000 t constraint	1.3% to 4.0%				

Table 5.8.1.1 Herring in VIa (N). Input data for short-term predictions, numbers at age from the assessment with ages 1 and 2 replaced by geometric mean values - natural mortality (M), proportion mature (Mat), proportion of fishing mortality prior to spawning (PF), proportion of natural mortality prior to spawning (PM), mean weights at age in the stock (SWt), selection pattern (Sel), mean weights at age in the catch (CWt). All biological data are taken as mean of the last 3 years. VIa (N) herring appears to have considerable annual variability in mean weights and in faction mature. Last years values are not applicable. N.B. In this table "age" refers to number of rings (winter rings in the otolith).

¹Calculated from estimates of weight per box and in some years estimated by-catch in the sprat fishery

³Based on sampling.

²Reported to be at a low level, assumed to be zero, for 1989-1995.

⁴Estimated assuming the same discarding rate as in 1986

Table 5.11.2 HERRING from the Firth of Clyde. Sampling levels 1988-2004.

Year	Reported catch (tonnes)	No. of samples	No. of fish measured	No. of fish aged	Discards

Short Series Changepoint All Risks

Less than 5% Risk

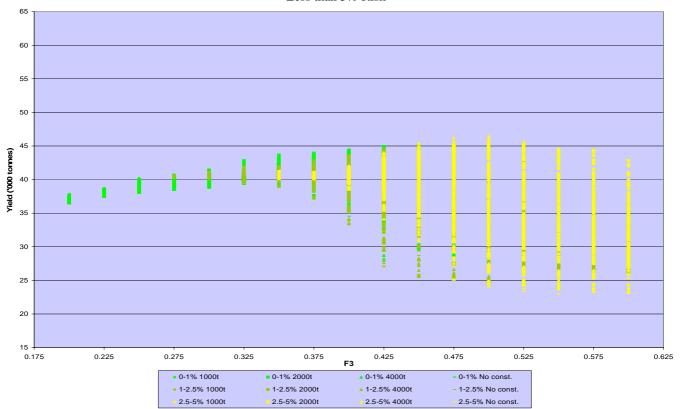

Figure 5.7.9 Herring in VIa (N), median yield in year 10 for Short time-series Change Point S/R relationship; yield verses long term F for the full range of HCRS studied, the colour indicates risk of SSB falling below Blim. Upper panel includes all risks, lower panel shows only risks less than 5%.

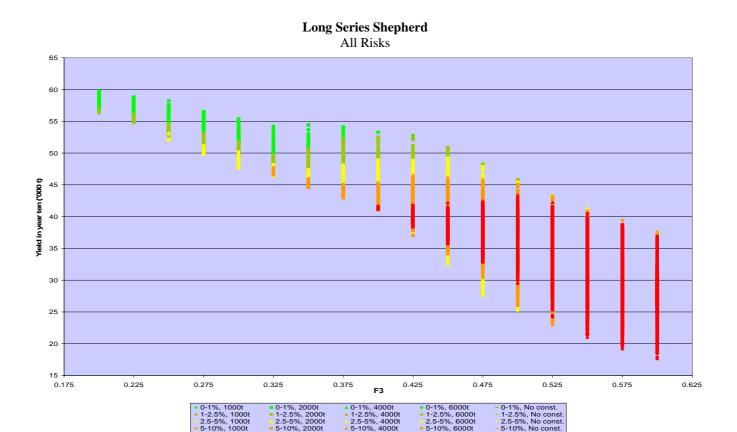

Figure 5.7.10 Herring in VIa (N), median yield in year 10 for long time-series Shepherd S/R relationship; yield verses long term F for the full range of HCRS studied, the colour indicates risk of SSB falling below Blim. Upper panel includes all risks, lower panel shows only risks less than 5%. Note the rise in yield with lower F.

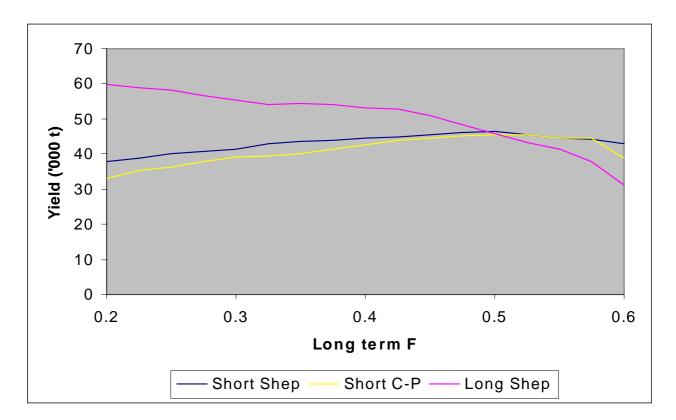

Figure 5.7.11 Herring in VIa (N), the maximum median yield in year 10 obtained for all HCRs with risk of SSB < Blim of less than 5% (Fig 8 to 10 lower panels) plotted against long term F for the three S/R relationships studied. Showing similarity for the two models for the truncated time-series and the higher yields at lower F for the longer time-series.

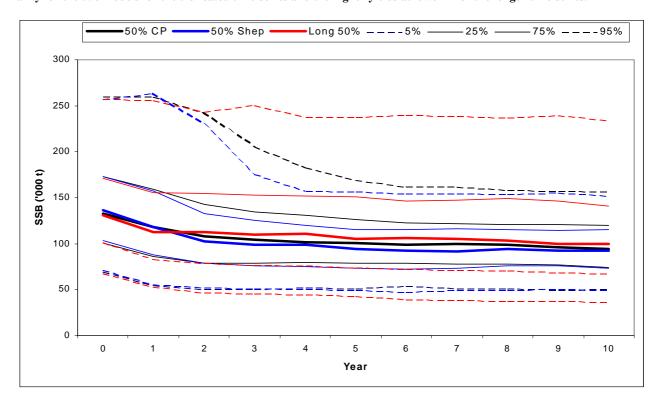

Figure 5.7.12 Herring in VIa (N), comparison of stock trajectory (5,25,50,75,95 percentiles) from current state of the stock assuming exploitation equivalent to the mean (0.36) and standard deviation (0.25) of the exploitation experienced since 1976. For the three main Stock Recruit relationships studied, truncated data series Change Point (CP) and Shepherd (Shep), and long data series Shepherd (Long). Showing that the expected state of stock depends little on the choice of stock recruit relationship if exploitation is at this level.

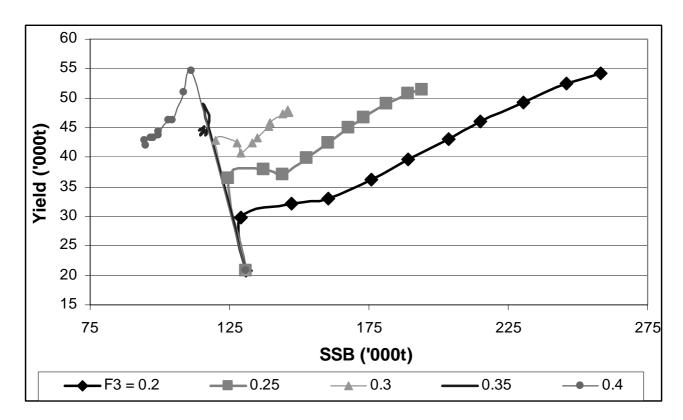

Figure 5.7.13a Herring in VIa (N), illustration of stock exploitation expressed as median yield v. median SSB for different long term Fs assuming the long time-series S/R model. Exploitation at F =0.35 gives approximate stability.

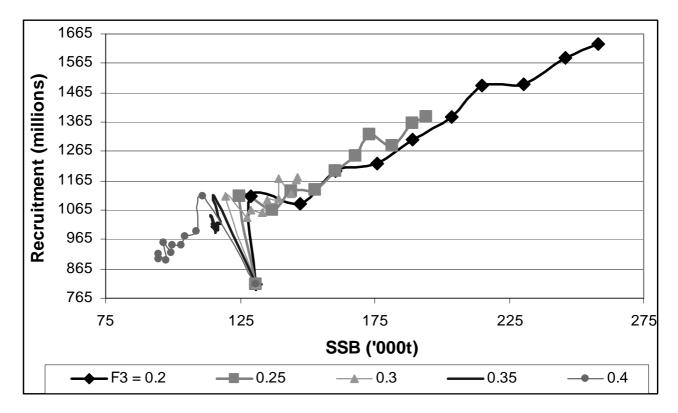

Figure 5.7.13b Herring in VIa (N), illustration of stock development expressed as median recruitment v. median SSB for different long term Fs assuming the long time-series S/R model. Exploitation at F=0.35 gives approximate stability.

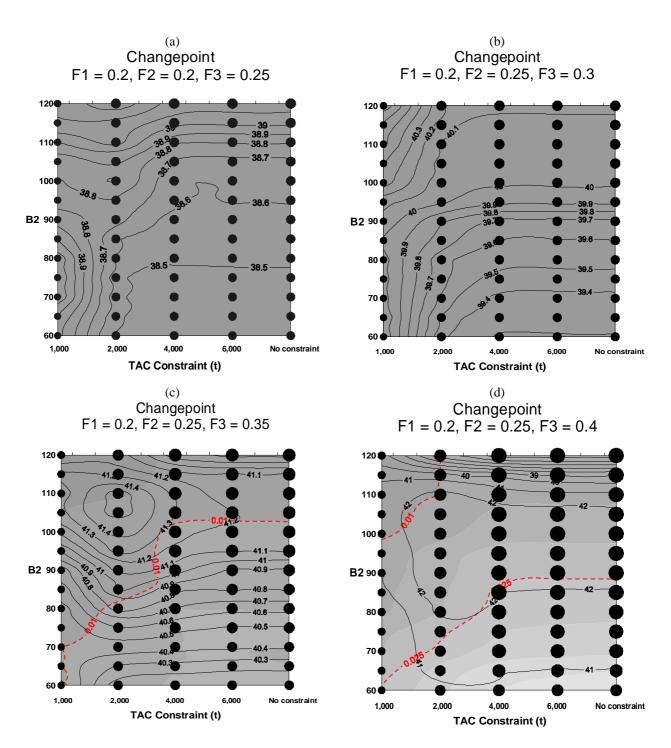

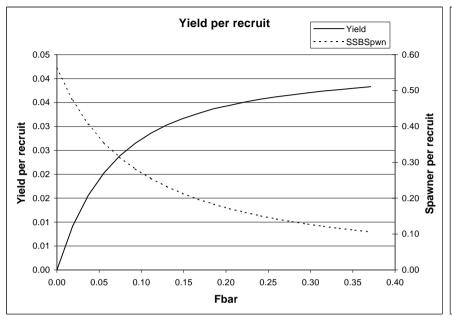

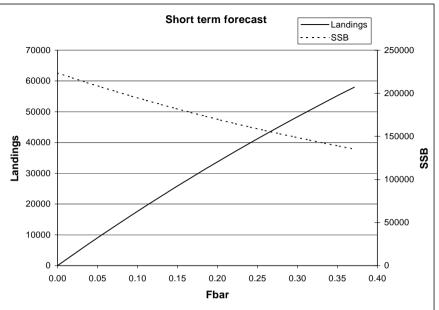

Figure 5.7.14 herring in VIa (N), comparison of yield (black contours), risk of SSB falling below Blim (colour dark grey low (0%), pale grey higher (5%)), and 5% to 95% spread of year to year change in TAC (black circles) for: F3 = 0.25 (panel a), F3= 0.30 (panel b), F3= 0.35 (panel c) and F3= 0.4 (panel d). Each panel is for values of biomass trigger (B2 in '000 t) on the vertical axis and for constraints in year to year change in TAC on the horizontal axis. The dotted contour lines represent risk values of 1% and 2.5%, panels a and b both fall below the 1% risk level, hence no dotted contour line present. There is an increase in risk from the top left corner of the panels to bottom right. This is clearly observed in panel d, where there is a low risk (<1%) in the upper left corner, increasing to 4% in the lower right.

The range of year on year change in TAC (black circles) goes from 1,700 t for the smallest circles up to 3,800 t for the largest.

The larger cohorts (1995, 1998 and 2000) are estimated more reliably.

6 Herring in Divisions VIa (South) and VIIb,c

6.1 The Fishery

The TAC for this area for 2004 was 14,000 t. This was the same TAC as the previous 6 years. For 2004, ICES advised that catches should not exceed 14,000 t. In 2004 ACFM considered the state of the stock to be unknown with respect to safe biological limits because estimates of SSB and fishing mortality were highly uncertain over the previous 2-3 years. The final year SSB was unknown but thought likely to be below B_{pa} (110,000 t). For SSB to be above B_{lim} (81,000 t) there would have to have been very strong recruitment in recent years but no evidence has been found for such year classes. The recent TAC's are approximately 50% of the average catches taken in the 1970's when the productivity of the stock was comparable to the present. ACFM considered that if SSB is not reliably found to be increasing, further catch reductions will be necessary, and that in the meantime, the fishery should not be allowed to expand.

In 2000, the Irish North West Pelagic Management Committee was established to deal with the management of this stock. The committee has the following objectives:

- To rebuild this stock to above the B_{pa} level of 110,000 t.
- In the event of the stock remaining below this level, additional conservation measures will need to be implemented.
- In the longer term it is the policy of the committee to further rebuild the stock to the level at which it can sustain annual catches of around 25,000 t.
- Implement a closed season from March to October.
- Regulate effort further through boat quotas allocated on a weekly basis in the open season.

This committee manages the whole fishery for this stock at present, given that Ireland currently accounts for the entire catch.

6.1.1 Catches in 2004

The working group estimates of landings from this fishery in 2004 are given in Table 6.1.1.1. Ireland is the dominant country in this fishery. Irish catch estimates for this WG have been based on the preliminary official reported data from the EU Logbook Scheme. The total Irish catch for 2004 was around 12,200 t, compared with almost 12,900 t in 2003. These data are an underestimate of the landings over this period September to December 2004. They are included for reasons of consistency with the time series of catches in this fishery (see Stock Annex, section B.1.).

The catches and landings recorded by each country fishing in this area from 1988–2004 are shown in Table 6.1.1.1. and the total catches from 1970 to 2004 are shown in Figure 6.1.1.1. There were no estimates of discards reported for 2004 and anecdotal reports from the industry are that discarding is not a major problem at the moment. The Irish catches by statistical rectangle in these areas are shown in Figure 6.1.1.2.

6.1.2 The fishery in 2004

The number of Irish vessels that participated in the fishery has remained static in recent years and fall into three categories. These are refrigerated seawater (RSW) vessels >40m, RSW vessels between 25 and 40m, and dry hold vessels all of which are under 25m in length. Quotas are allocated on a fortnightly basis and there is some capacity to carry unused allocation into the following fortnight with overruns being deducted. Most fish are landed into Killybegs with smaller amounts going to Rosaveal and Dingle further south. As in the Celtic Sea the grounds furthest offshore are the preserve of the larger RSW vessels and this applies in particular to those grounds on the borders of VIa north and VIa south. In the case of larger boats there may also be a tendency to prioritise effort for mackerel and horse mackerel and take their herring allocations opportunistically. The dryhold boats, not having the same access

to these stocks direct all their effort at herring until the fisheries close. About thirty vessels participated in the fishery in 2004.

The great majority of fish in VIIbc and VIa south are landed in the first and fourth quarter from grounds around the northern boundary of VIIb along the north Connacht coast, the southern boundary of ICES division VIa south around Donegal Bay, and off Co. Donegal from off Tory Island to Inishtrahull. In 2004 fishermen reported that the fishing in the fourth quarter improved from the first quarter in terms of the availability of fish. In particular they remarked on the strength and resilience of herring marks on the traditional inshore grounds around Counties Donegal and Mayo. Figure 6.1.1.2 shows the distribution of catches by statistical rectangle and quarter and Figure 6.1.2.1 shows the herring spawning grounds of north west Ireland.

The pattern of this fishery has changed over time. In the early part of the 20th Century the main spawning components were the winter spawners off Co. Donegal, and this was where the main fishery took place. In the 1970's and 1980's the west of Ireland autumn spawning components were dominant and the fishery was mainly distributed along west Connacht, in Counties Galway and Mayo. More recently the northern grounds are more important again with most of the catches from VIIb concentrated between Clew Bay and Killala near to the boundary of VIa south.

In 2004 there was a greater range of lengths in fish caught in the fourth quarter than in the first (Table 6.1.2.1). A particular aspect of the first quarter fishery in VIa S has been the appearance of large fish off the north Donegal coast in February. These fish are usually over 31 cm TL.

6.2 Biological composition of the catch

6.2.1 Catch in numbers-at-age

The catches-at-age for this fishery since 1970 are shown in Table 6.2.1.1. In recent years the catch numbers at age have been derived from Irish sampling data. The dominant year classes in 2004 were the 2, 3, and 4 ringers accounting for 18% and 38% and 23% respectively. In the short term the relative proportions of 2, 3 and 4 ringer fish have remained quite stable. However over the entire life time of the data series the relative proportions of 2, 3, and 4 ringers in the catches have shown an increasing trend. The percentage contribution of 6 ringers and older has declined over the time series (Table 6.2.1.2).

6.2.2 Quality of the catch and biological data

The management of the Irish fishery in recent years has tightened considerably and the accuracy of reported catches is also believed to have improved. The numbers of samples and the associated biological data are shown in Table 6.2.2.1. Changes in targeting by sections of the fleet mean that there is now a need to get more samples from the larger RSW vessels and from the opportunistic catches that occur in south VIIb. It is worth noting that sampling in this fishery relies heavily on the small RSW and dry hold sector which concentrate on the inshore grounds. This might lead to the proportion of older ages being underestimated in the sample data

6.3 Fishery Independent Information

6.3.1 Ground Fish Surveys

There are currently no recruitment indices available for this stock. However an Irish ground fish survey conducted in the area since the early 1990's regularly catches herring. Preliminary investigations show that this survey is of little utility as a herring recruit index, because gear, timing and survey vessel changed throughout. However, the western IBTS, may be useful, when a time series becomes available.

6.3.2 Acoustic Survey

The total biomass estimate for the area surveyed was 41,693 with a SSB of 41,300, the highest in the series, and much higher than 10,300 t biomass t and 9500 t SSB in 2003. The 2005 survey estimate is still in preparation, but it is highly likely that it will produce a higher estimate of SSB. This is because good registrations of herring were obtained, see below. However both surveys did not fully contain the stock, and are thus underestimates of stock size. In 2006, the usefulness of this acoustic time series will be explored. At that point, an 8 survey series should be available.

In the mid 1990's, surveys were carried out in summer, however since 1999, surveys of this stock have been carried out in winter. A description of acoustic surveys in this area is presented in Table 6.3.2.1. The 2004 survey was carried out on the RV *Celtic Explorer*, and was the first such survey on the new vessel. It took place from the 5th to the 20th January 2004. The survey covered an area extending from Inishtrahull to west of Glen Bay, from close inshore to up to 50 nm (nautical miles) offshore, the northern limits of Sub-Division VIaS. Survey track and trawl positions are shown in Figure 6.3.2.1 and S_A values and their distribution on the survey track are shown in and Figure 6.3.2.2. A persistent challenge of the winter acoustic survey series has been synchronising the survey with the peak spawning event to ensure containment of the stock within the survey area.

Spawning is thought to proceed in a succession of waves with older fish being the first to arrive on the spawning grounds. The maturity stages encountered and the size composition of the survey catches were taken as an indication that the stock may not have been fully contained by the survey and that the first wave of spawning had been completed at the time of the survey. The majority of fish recorded during the survey were ripe, accounting for 56% of the biomass and 53% of the numbers. Spent fish accounted for 43% of the total biomass and 45% of the total numbers. The catches in the survey were characterised by the high numbers of older fish especially compared to the commercial catches (Figure 6.3.2.3). Fishing success was reasonably good, although the majority of the estimate was attributed to "herring in a mixture" and "probably herring". Anecdotal information from fishermen suggests peak spawning time now occurs between January and February.

Age distributions and abundance estimates for acoustic surveys are shown in Table 6.3.2.2. The age distributions of the abundance estimate from the survey and of the commercial fishery in 2004 along with abundance estimates for the 2003 and 2004 surveys and the raw estimates for the 2005 survey, are presented in Figure 6.3.2.3. The dominant ages in the acoustic survey in 2004 were the 3 to 6 ringers compared to 2, 3 and 4 ringers for the fishery over the whole season. When the survey age distribution is compared with that portion of the fishery that took place in the same quarter the lag in ages is even greater, as the proportion of two year olds in the fishery is even more pronounced in this quarter than in the year as a whole. This might be a further indication that the stock is not contained in the survey.

In 2005, the VIaS and VIIb winter acoustic survey was conducted on the Celtic Explorer from the 5th to 26th January. There were severe storms for the first week and in addition, a breakdown kept the vessel in port for part of the survey. However this allowed for a high degree of consultation with the fishermen and the survey track was then adapted to obtain the best coverage of fish distribution.

In contrast to the 2004 survey, in 2005 most of the herring traces were assigned as "definitely herring" and were associated with large homogeneous schools. Fishing success was high with many hauls of mostly herring. On the Mayo coast the fish were mostly spent (stage 7), this area is of autumn and winter spawners. Off Donegal the majority of fish were ripe or running (stages 5 and 6). This indicates that the timing coincided well with the full range of the spawning season, having covered the western fish before they dispersed and the northern fish just as they were arriving at the beds. The abundance and biomass estimates are in preparation. However it is clear that this survey will produce the highest estimate of stock size yet. This experience is in line with the very good fishing reported by the fishing industry in 2004 and 2005.

6.4 Mean weights-at-age

The mean weights (kg) at age in the catches in 2004 are based on Irish catches and are very similar to 2004 for ringers 1-6 (Table 6.4.1). These mean weights in recent years display quite a stable pattern over the time series. Though there appears to be a slight increase in mean weights in the past three years (Figure 6.4.4.1).

The mean weights in the stock at spawning time have been calculated from Irish samples taken during the main spawning period that extends from October to February (Table 6.4.2). As in the mean weights at age, in recent years mean weights in the stock appear quite stable for the majority of age groups (Figure 6.4.4.2.). However a more pronounced increase in size among the older groups may indicate there have been changes in targeting in the fishery.

6.5 Recruitment

There is little information on recruitment in the catch at age data and there are as yet no recruitment indices from the surveys.

6.6 Stock Assessment

There is no reliable tuning series for this stock, and tuned assessments have not been carried out for a number of years. Recently, the group has carried out separable VPA's, screening over a range of terminal F's. This approach allows for a study of the development of the stock, but prevents any conclusions being made about stock status in the most recent years.

6.6.1 Data exploration and preliminary assessments

6.6.1.1 Trends and patterns in basic data

There have been no obvious year class effects in the catch at age matrix since the mid nineteen nineties (Table 6.2.1.1 and Figure 6.6.1.1).

From around 1985 to 1995 older fish, 5 rings and older, dominated the catches. Prior to that the age profile of the catches was relatively stable. Since 1998, when catches attained 38,000 t, younger fish, i.e. <5 ring,s have dominated the age profile of the catches.

This pronounced shift in the age composition of the catches from old fish to young fish has been maintained, and 2, 3 and 4 ringers now make up the bulk of the catch.

While the numbers of large fish in the catches have fallen the rate at which they are being removed has remained relatively high. This is reflected in the bunched catch curves in the Log of catch numbers by year class in Figure 6.6.1.2.

There is further evidence in the catch and sampling data to show that the catch rates for older age groups has continued to increase even as their proportion in the total catch decreases. See log catch ratios and smoothed log catch ratios in Figure 6.6.1.2. These show an upward trend for all fully recruited year classes in the last three years with the exception of 3 to 4 ringers. Overall, the catch sample data show a diminishing range of ages in the catches and older fish are at their lowest levels in the catches since the time series began.

It is unclear from our understanding of current understanding of fleet dynamics as to whether older fish have been fished out or if changes in targeting have shifted the selection pattern to younger fish.

Comparison of acoustic survey and fisheries data show differences in the relative strength of year classes. (Fig 6.3.2.3). There are also strong year effects in the acoustic survey data that do not appear in the fishery data. These are the 2 and 5 ringers in years 2002 and 2004 (Table 6.3.2.2).

A separable VPA was used to screen over three terminal fishing mortalities, 0.2, 0.4 and 0.6. This was achieved in the Lowestoft VPA software (Darby and Flatman, 1994). Reference age for calculation of fishing mortality was 3-7 and terminal selection was fixed at 1, relative to age 4 (winter rings). Default downweighting was chosen. This assessment is still experimental, and no assessment has been accepted by ACFM in recent years.

6.6.2 Results of the assessment

Three assessments are presented, based on the three choices of terminal F. Without access to a sufficient time series of tuning data, the group was unable to make an informed choice between them. The general development of the stock is presented in Figure 6.6.2.1. Last year's results are included in this figure, for comparative purposes. This figure is more informative for earlier years, but in most recent years has little information on the situation. Outputs from separable VPAs with terminal F's of 0.2, 0.4 and 0.6 are presented in Tables 6.6.2.1, 6.6.2.2 and 6.6.2.3 respectively. Residual plots for the three trial assessments are presented in Figures 6.6.2.2 to 6.6.2.4, respectively.

Under the two more optimistic scenarios of terminal F, the current assessment suggests declining fishing mortality since 2001. However, using a terminal F of 0.6 suggests an increase in fishing mortality in 2004. The landings have been declining slightly since 2000, and this may provide evidence that terminal F's in the range 0.2 to 0.4 are more realistic.

Recruitment appears to have remained stable at a low level, under the more pessimistic scenarios, or increased very slightly. These results are consistent with the preliminary data screening, that shows no stronger year classes in the fishery in recent years (Section 6.6.1). Using a terminal F of 0.2, produces a slight increase in recruitment in 2004. However these 1-ringer fish are poorly selected in the fishery and thus there is little information in the catch at age matrix on their strength in the final year. This can be seen with reference to the residual plots (Figure 6.6.2.2)

SSB is either stable at a low level or declining slightly, assuming terminal F of 0.6. If SSB is stable, it is stable at the lowest level in the series. In interpreting these data, it should be noted that herring is not entirely a target fishery in this area at present.

6.7 Stock Forecasts and Catch Predictions

In the absence of an agreed assessment, it was not considered informative to carry out any predictions.

6.8 Medium Term Projections

No medium term projections were carried out for this stock because of the absence of information. A management plan is currently being implemented to rebuild this stock.

6.9 Reference Points

As this assessment is still uncertain there was no revision of the precautionary reference points. The precautionary reference points for this stock were discussed in the 1999 Working Group Report (ICES 1999 ACFM:12). The present analysis, although uncertain, presents a similar picture of the stock as that shown in recent years. The SGPRP (ICES 2003/ACFM: 15) has reviewed the methodology for the calculation of biological reference points, and applying a segmented regression to the stock and recruit data from the 2002 HAWG assessment showed that the fit to the stock and recruit data for this stock was not significant. The stock is still likely below Bpa (110,000 t) but the fishing mortality has been reduced, since 1998.

6.10 Quality of the Assessment

The assessment presented was based on the results from a separable VPA without a tuning index, therefore the estimates of SSB and F for recent years depend on the choice of terminal F. Although landings seem to have been low and stable in recent years the real F cannot be determined. Therefore the VPA was run for a range of terminal F values and the current per-

ception of the stock would be highly influenced by that choice. Further, there is no information on recent recruitment levels both because the selectivity of the fishery appears to be low for the juveniles and for the lack of a recruitment index.

As some of the components of the fishery are opportunistic changes in fishing patterns are to be expected. Consequently catch at age data is likely to be a poor indicator of cohort decline. A consistent time series of fishery independent data would provide a tuning fleet that would improve the assessment.

The group considers that the survey series available since 1999 is problematic because the surveys before 2001 were targeting autumn spawners, and those afterwards were targeting winter spawners. In 2006, five winter surveys will be available as a time series and this should be considered in tuning the assessment.

Unallocated/misreported catches are not considered to have a large effect on the assessment at present.

6.11 Management Considerations

The results of the non-tuned assessment suggest that the sharp decline in SSB may have stopped but the current level of SSB is uncertain. There is no evidence that large year classes have recruited to the stock in recent years and F appears to have been reduced due to the reduction in catch. The management of the Irish fishery (which takes most of the catch) has improved in recent years and catches have been considerably reduced since 1999. The reduced catches over this period have resulted in a reduction in fishing mortality, although it is not possible to be precise about the current levels.

SSB may be stable at an historic low level or declining slightly. Though the peak in SSB in the 1980's may have been an isolated event the HAWG suggests that this stock should be exploited with great caution. F appears to have been substantially reduced since 1998. Though little information on recruitment is available, it is unlikely that it is above average. Certainly every effort should be taken to maintain catches at or below the current level. In particular the HAWG commends the tight enforcement of catch quotas, and this should be continued and if necessary intensified.

The opportunistic nature of the fishery means that there is a lack of information in the data and this impedes the provision of more accurate perceptions of stock status. There are essentially two fleets exploiting this stock, the smaller dry hold vessels tend to target the stock more than the larger boats. The HAWG notes that increased accuracy in the catch data over the past 3 years gives a greater confidence in the perception of stock development. It will be necessary to collect biological data from each fleet separately, in order to refine the information from catch at age data. In order to obtain a proper assessment of this stock for the most recent years, reliable survey data are required. The current acoustic survey index dates from 1999. By the next working group, 8 years of data will be available and it should be possible to use this a tuning index. However the timing of the surveys means that they only cover part of the stock.

Anecdotal information and observations by scientists shows that industrial fisheries have been in operation in the area just north of the boundary of VIaN and VIaS. The Stanton Bank, in this area, is known as a juvenile herring area and as an area for feeding of VIaN, VIaS and VIIaN herring. The by-catch of herring in industrial fisheries in this area should be evaluated.

7 Irish Sea Herring [Division VIIA(North)]

7.1 The Fishery

7.1.1 Advice and Management Applicable to 2003 and 2004

ACFM did not accept the HAWG 2003 and 2004 assessments due to conflicting signals in the survey data, a lack of a recruitment index, and the possibility of more than one stock in the management area. HAWG noted that although only juveniles from different stocks mix in the Irish Sea, the stock identity of the adults is clear. ACFM commented in 2004 that current exploitation levels appear to give a relatively stable stock. The advice was a TAC equal to that in 2004 (4,800 t). This TAC was subsequently adopted for 2005. This was partitioned as 3,550 t to the UK and 1,250 t to the Republic of Ireland.

7.1.2 The fishery in 2004

The catches reported from each country, for the period 1986 to 2004 are given in Table 7.1.1 and total catches from 1961 to 2004 in Figure 7.1.1 (catch-at-age in Figure 7.2.1). Reported international landings in 2004 for the Irish Sea amounted to 2531 t. The UK took only 50% of its quota for 2004, whilst the Republic of Ireland took 60% of its quota.

As in recent years, very few vessels targeted herring in the Irish Sea in 2004. 70% of the total international catch was taken during the 3rd and 4th quarters of the year by a single team of pair-trawlers from Northern Ireland. These vessels commenced fishing in mid August and made their final landing of herring at the end of October.

Closed areas for herring fishing in the Irish Sea along the east coast of Ireland and within 12 nautical miles of the west coast of Britain were maintained throughout the year. The area to the east of the Isle of Man, encompassing the Douglas Bank spawning ground (described in ICES 2001, ACFM:10), was closed from 21 September to 15 November. Boats from the Republic of Ireland are not permitted to fish east of the Isle of Man.

7.2 Biological composition of the Catch

7.2.1 Catch in numbers

Catches in numbers-at-age are given in Table 7.2.1 for the years 1972 to 2004 and a graphical representation is given in Figure 7.2.1. The predominant year class in 2004 was the 2- ringers (2002-year class), with the relatively strong 1996 year-class still detectable. The catch in numbers at length is given in Table 7.2.2 for 1990 to 2004.

7.2.2 Quality of catch and biological data

There are no estimates of discarding or slippage of herring in the Irish Sea fisheries that target herring. Biological sampling was carried out on seven out of the 18 landings (1,770 t) made by the Northern Ireland pair-trawlers. Two landings into the Republic of Ireland (from a total of 749 tonnes landed) were sampled.

7.3 Fishery-independent information

7.3.1 Acoustic surveys

The information on the time-series of acoustic surveys in the Irish Sea is given in Table 7.3.1. As in last year's assessment, the SSB estimates from the survey are calculated using the same

(annually varying) maturity ogives that are input to ICA (see Table 7.4.3; estimated from the commercial catch data).

The acoustic survey in 2004 was carried out over nine days in the period 6 to 29 September, with poor weather stopping the survey from 17 –27 September. A survey design of stratified, systematic transects was employed, as in previous years. Very few trawl catches of adult herring have been made off the Irish and English coasts over the time-series of the surveys, and a more intensive survey of these regions, at the expense of time spent around the Isle of Man, remains unwarranted at present. In general, there are few samples on the age composition of the herring in the acoustic survey data. The survey followed the methods described in Armstrong et al., 2005 WD 23; see Annex 7).

The bulk of the acoustic scatter attributed to pelagic fish was identified as sprat, which were abundant around the periphery of the Irish Sea (Fig. 7.3.1.1.B). Mixed herring targets were detected at a number of locations off the west and south coasts of the Isle of Man (Fig.7.3.1.2.A). Trawl samples taken inshore off the west coast of the Isle of Man contained predominantly 1-ringers or a mixture of predominantly 1 – 4 ringers with some older fish. Variable size/age composition was also recorded in two trawl catches inshore off the NE coast of the Isle of Man. The distribution of 1+ ring herring around the Isle of Man was similar to the pattern observed by a team of commercial pair trawlers operating at the same time. Herring mixed with sprat were predominantly 0-ringers, and these were most prevalent in the identification trawls made off the northwest coast of the Isle of Man (Fig. 7.3.1.2.B).

As in previous years, no herring schools were detected in the area immediately north of the Isle of Man, despite an abundance of early-stage larvae in this area in November (Figure 7.3.2). It is possible that spawning in this area only commences after the date of the acoustic survey.

The estimate of herring SSB of 21 kt for 2004 was slightly above the average for the series up to 2003 (20 kt) (Table 7.3.1.1). The approximate coefficient of variation of 0.41 was close to the average for the series of surveys. The biomass estimate for 1+ ringers (34 kt) was slightly above the average for 1994-2003 (33 kt), whilst the approximate CV of 0.41 for the stratified mean estimate was above-average for the series. Given the approximate CVs of the estimates, it is not possible to discern any trend in 1+ biomass or SSB since 1999.

The estimated age composition of the herring population, excluding 0-ring fish, is given in Table 7.3.1.2.

7.3.2 Larvae surveys

A larvae survey was undertaken by Northern Ireland (30 October - 3 November 2004) but there was no survey by the Port Erin Marine Laboratory. The survey followed the methods and designs of previous surveys in the time-series (see Annex 7). The production estimate for 2004 in the NE Irish Sea was slightly below the average for the previous years (Table 7.3.2). As in recent years, there were very few larvae caught off the Mourne coast (Northern Ireland), Figure 7.3.2.

7.3.3 Groundfish surveys of Area VIIa(N)

Groundfish surveys (see Annex 7), carried out by Northern Ireland since 1991 in the Irish Sea, were used by the 1996 to 1999 Herring Assessment Working Groups to obtain indices for 0-and 1-ring herring in the Irish Sea. These indices have performed poorly in the assessment and have not been used since 1999. Indices for 1991 – 2003 are shown in Table 7.3.3. The 2004 indices were not available at the time of the WG.

7.4 Mean length, weight, maturity and natural mortality-at-age

Mean lengths-at-age were calculated using the catch data and are given for the years 1985 to 2004 in Table 7.4.1. In general, mean lengths have been relatively stable over the last few years.

Mean weights-at-age in the catch are given in Table 7.4.2. Mean weights-at-age of all ages were still generally low compared with previous years. There has been a change in mean weight over the time period 1961 to the present (ICES 2003 ACFM:17). Mean weights-at-age increased between the early 1960s and the late 1970s whereupon there was been a steady decline to the early 1990s. In the assessment, mean weights-at-age for the period 1972 to 1984 are taken as unchanging. In extending the data series back from 1971 to 1961, mean weights-at-age in the catch were taken from samples recorded by the Port Erin Marine Laboratory (see ICES 2003 ACFM:17).

Mean weights-at-age in the third-quarter catches (for the whole time-series 1961 to present) have been used as estimates of stock weights at spawning time. There was some uncertainty in the mean weights-at-age for 2003 presented to the WG last year, and consequently the WG replaced these with the average mean stock weights-at-age for the preceding five years (1998 – 2002). There was no further information this year to improve the 2003 values, and these remain as the 5-year mean.

Maturity-at-age (in the catches) for each year (1961 to 2004) are given in Table 7.4.3. Due to inconsistencies in the maturity data collected in 2003, last year's WG used a mean maturity ogive for the preceding nine years for 2003. The rationale for the 9 years was that there appeared to be a shift in the maturity ogive around 1993. As with the stock weights, the figures used last year have not been revised. Both mean weights and maturity at age for 2004 were based on 2004 biological samples.

As in previous years, natural mortality per year was assumed to be 1.0 on 1-ringers, 0.3 for 2-ringers, 0.2 for 3-ringers and 0.1 for all older age classes. These are based on the natural mortality rates estimated for herring in the North Sea using MSVPA.

7.5 Recruitment

An estimate of total abundance of 1-ringers is provided by the Northern Ireland acoustic survey. However, there is evidence that a fraction of those is of Celtic Sea origin. Separation of the trawl catches of juveniles into autumn and winter spawning components, based on otolith microstructure and/or length composition, could result in a survey index of recruitment for the Irish Sea stock that could be used directly in the assessment.

7.6 Stock Assessment

7.6.1 Data exploration and preliminary modelling

This year previous ICA assessment was updated and no extensive exploration of alternative assessment models was carried out. In 2004 three fishery independent survey indices were used as tuning indices to run ICA: Douglas Bank larvae abundance (DBL), Northern Irish larvae production (NINEL) and the age dis-aggregated abundance index from the acoustic survey (ACAGE). Also, the preliminary modelling used catch-at-age data derived from the official landings, extended back to 1961.

This year new data were added to the Northern Irish larvae series (NINEL) and to the Northern Irish acoustic survey (total biomass, SSB and age-structured indices). No new data were added to the Douglas Bank larvae series (DBL). Due to the problems associated with mixing of Irish Sea and Celtic Sea juveniles none of the groundfish surveys were considered suitable

tuning fleets. The survey series available for inclusion in an assessment using the ICA package are documented in Appendix 7.

Initial fits within integrated catch-at-age analysis (ICA), were performed with DBL, NINEL and ACAGE. The following model settings were used:

- Separable constraint over the last 6-years (weighting = 1.0 for each year)
- Reference age = 4
- Constant selection pattern model
- Selectivity on oldest age = 1.0
- First age for calculation of mean F = 2
- Last age for calculation of mean F = 6
- Weighting on 1-rings = 0.1; all other age classes = 1.0
- Weighting for all years = 1.0
- All indices treated as linear
- No S/R relationship fitted
- Lowest and highest feasible F = 0.05 and 2.0
- All survey weights fitted by hand i.e., 1.0 with the 1-rings in the acoustic survey weighted to 0.1.
- Correlated errors assumed i.e., = 1.0
- No shrinkage applied

The initial fit corresponds to the same procedure as last year (SPALY).

Examination of the sum of squares surface from SPALY indicated that the Douglas Bank larvae index (DBL) was having no influence in the assessment estimates for the current year. Therefore, the WG agreed on removing DBL from the analysis. Examination of the SSQ surface (Fig. 7.6.1) shows a relatively clear minimum where both indices coincide. Estimates of uncertainty from the ICA bootstrapped mean F and SSB for SPALY and the NINEL-ACAGE run are shown in Figure 7.6.2. The comparison highlights a gain in precision for both F and SSB in the NINEL-ACAGE run. Comparison with similar plots produced in 2004 (not shown) indicates an increase in precision in the 2005 assessment compared to 2004.

Examination of the exploitation rate estimated as the ratio of the catch to the acoustic estimated 1+ biomass carried out in 2004, suggested an increase from 1995 to 1998 and a relatively lower exploitation rate over the period 1999 to 2003, suggesting that the fishing mortality had probably been relatively stable over this time period. The analysis was not repeated this year but uptake in 2004 has been low and preliminary calculations result in a similar exploitation rate to the ones computed for 2002 and 2003. Moreover, the fleets did not take their full quota (4,800 t) in 2004, therefore there is every possibility that fishing mortality in 2004 did not rise dramatically. These low levels of fishing should allow the stock to maintain a status quo SSB, if not allow the SSB to rise.

Two-stage biomass model

An Assessment of Irish Sea VIIa herring using a Two-Stage Biomass model given additional variance in the recruitment index was presented by Roel and De Oliveira (2005 WD10). The authors further developed the two-stage biomass model they presented in 2004. This year, a more constrained model (e.g. not allowing the recruitments to vary so freely) with only one catchability parameter was attempted to address concerns of over-parameterisation. Also, estimation of the component of the variance resulting from the occurrence of juvenile Celtic Sea herring mixed with Irish Sea herring in the survey area was attempted by introducing an extra parameter: the additional variance (λ^2). A better fit to the data was obtained when recruit-

ment was allowed to vary more freely which is to be expected. However, in that case the estimated additional variance which could reflect the variability related to the Celtic sea recruits is practically zero which is an unlikely outcome. Alternatively, when recruitment variability is further constrained the additional variance, although imprecise, represents a large component of the total 1 year-old biomass variability. On the basis of these results the authors concluded that additional information on the variability of Irish Sea herring recruitment is required to estimate additional variance in the context of the two-stage biomass model presented.

Conclusion to explorations

The results from the exploratory runs carried out with ICA using NINEL and ACAGE as tuning indices indicate an increase in precision compared to 2004. Moreover, the clear minimum in the SSQ surface graph suggests good consistency between the separable model and the indices. Therefore results from the assessment are presented in this report.

7.6.2 Stock Assessment

The results presented correspond to ICA runs using the acoustics data as an age-structured index (ACAGE) and the Northern Ireland larval survey (NInel) as an index of biomass. The model settings are the same as for 2004. The run log for the assessment is shown in Table 7.6.1. The output from ICA assessment, the residuals and fitted values are given in Tables 7.6.2 - 19. The SSQ for the index shows a clear minimum at a relatively low level of fishing mortality (Figure 7.6.1). The model diagnostics (Figure 7.6.3) show that the total residuals by age between the catch and the separable model are reasonably trend-free, however although the sum of the year residuals are small, they show a negative pattern. The estimate for $F_{(2-6)}$ for 2004 was 0.18 (Table 7.6.15) with a corresponding SSB estimate of approximately 11,100 tonnes, well above Bpa = 9500 tonnes.

The assessment results do suggest that the stock has been relatively stable in recent years. A slight increase in SSB is shown in 2004 (Fig 7.6.4). This increase is not the result from the increase in the 2004 larvae index, which is below the estimated trend in SSB (Fig. 7.6.5). Rather it appears linked to the large estimate of numbers of 2 years-old in the ICA assessment. Further, the acoustic survey estimated large numbers of 2 year-olds and as this information was not in contradiction with the catch data, ICA fitted the acoustic data closely, resulting in the increase in SSB mentioned above (Fig. 7.6.6). This year-class is fully mature (Table 7.4.3) so it will be contributing substantially to the SSB.

The log-residual plot for the separable period (Fig. 7.6.3) suggests variability in the selectivity for the separable period probably related to a predominance of young fish in the catches compared to previous years. However, there is no direct information of a major shift in selection pattern within this fishery in recent years. Comparison between the selection pattern estimated in the current assessment and the SPALY run in 2004 (Fig. 7.6.7) show differences in selection regarding the younger years which illustrates de level of uncertainty in the estimates.

7.7 Stock and Catch Projection

7.7.1 Deterministic short-term predictions

Two scenarios for deterministic short-term predictions are presented: $F_{status\ quo}$ for 2005 and TAC constraint = 4800 tonnes. This is because the current effort in the fishery results in underfishing of the TAC. Short-term projections were carried out using MFDP. Input data are the historic time series used in the ICA assessment with geometric mean (1980-2002) replacing recruitment 1-wr in 2005 and 2006. 2-wr in 2005 resulted from assuming geometric mean recruitment in 2004 and taking into account mortality. Input data is shown in Table 7.7.1. The

selection pattern used is as estimated by ICA. For the projections data for maturity, mean weights-at-age and natural mortality are the means of the three preceding years.

The results of the short-term projections are shown in Tables 7.7.1. to 7.7.3. The short-term forecast for landings and SSB at status quo F is shown in Fig 7.7.1. Results from short-term predictions suggest that regardless of the constraints assumed for 2005 ($F_{st quo}$ or TAC), estimates of SSB in 2006 are well above Bpa = 9,500t. Assuming $F_{st quo}$ in 2005, SSB remains at about 14,000 tonnes in the short-term.

7.7.2 Yield-per-recruit

A yield-per-recruit analysis was carried out using MFYPR to provide a yield-per-recruit plot for VIIa (N) (Fig. 7.7.1). The values for F0.1 and F35% SPR are 0.16 and 0.14 respectively. These may be compared with the current F of 0.18 as estimated by the assessment.

7.8 Medium-term predictions of stock size

The Working Group decided that there was no basis for undertaking medium-term projections of stock size until there is agreement that advice based on the assessment can be provided.

7.9 Reference points

The estimation of \mathbf{B}_{pa} (9,500 t) and \mathbf{B}_{lim} (6,000 t) were not revisited this year. There were no new points to add to the discussions and deliberations presented in 2000 (ICES 2000/ACFM:12).

7.10 Quality of the Assessment

Retrospective analysis of the assessment with data from 2001 to 2004 was carried out. Figure 7.9.1 shows the retrospectives for SSB and F_{2-6} from the ICA assessment (NINEL + ACAGE) with a 6-year separable period. These retrospectives show rather stable estimation of SSB at a level just below B_{pa} and though there was a tendency to over-estimate SSB in the last assessment year, adding data in 2005 practically did not revise the 2004 estimates. The retrospective pattern of F_{2-6} is relatively stable and although there was a tendency to revise F upwards for 2003 and 2002, the addition of data in 2005 had very little effect on the 2004 estimates. F_{2-6} is likely to be at a lower level than during the mid 1990's and seems to have stabilized at this low level in the past 4 years.

The very large deviation seen in the recruitment retrospective results from the extremely high estimate of recruitment in 2002 (Figure 7.9.1). As information on recruitment is downweighted in both the catch at age and the survey, that is not surprising.

For some years, the assessment for this stock has not been accepted by ACFM. Both the catches and survey data are noisy. This year the assessment seems to have improved as more years are added to the acoustic survey series, and the conflicting signals in survey data seen in previous assessments are not observed in this assessment. Given the noise in the data it is difficult to detect abrupt changes in the stock dynamics. Nevertheless some inferences can be made that are quite robust, even though the absolute estimates of SSB and fishing mortality may be less reliable. In particular, it seems likely that the stock is relatively stable at a level close to Bpa, and that the fishing mortality has been low since the late 1990's. Therefore, an advice to maintain catches at the current level is supported by the assessment.

7.11 Spawning and Juvenile Fishing Area Closures

The arrangement of closed areas in Division VIIa(N) prior to 1999 are discussed in detail in ICES (1996/ACFM:10) with a change to the closed area to the east of the Isle of Man being altered in 1999 (see ICES 2001/ACFM:10). The closed areas consist of: all year juvenile clo-

sures along part of the east coast of Ireland, and the west coast of Scotland, England and Wales; spawning closures along the east coast of the Isle of Man from 21st September- 15th November, and along the east coast of Ireland all year round. The Working Group recommends that any alterations to the present closures are considered carefully, in the context of this report, to ensure protection for all components of this stock.

7.12 Management considerations

The different survey series for Irish Sea herring are characterized by generally poor precision caused by the very patchy distribution of the fish as well as assumptions inherent in the methods (e.g. target strength, larval growth and mortality; relationship between larval production and SSB). Nonetheless, there is evidence of some coherence between the longer-term signals in the different survey series. The acoustic survey provides estimates of abundance at age but the juveniles in the area are a mixture of two adjacent stocks (Celtic Sea and VIIa(N)). Separation of trawl catches of juveniles into autumn and winter spawning components, based on oto-lith microstructure and/or length composition, could result in acoustic and trawl survey indices of juveniles appropriate for the Irish Sea assessment.

The catches have been low in recent years and there are no indications of problems in the catch-at-age for this stock. An improvement in precision was noted in this assessment and SSB is estimated to be above B_{pa} . However, analytical retrospectives show that considerable downward revision of SSB took place in subsequent assessments in recent years. The current assessment indicates that SSB is relatively stable. Further, a broad range of year classes is present in the stock. Therefore, the maintenance of recommended catch levels of approximately 5,000 t, in the short-term, should not be detrimental to the stock.

Enter new weights for specified years and ages if needed
Is the last age of FLT01: Northern Ireland acoustic surveys a plus-group (Y--
You must choose a catchability model for each index.
Models:
        A Absolute: Index = Abundance . e
        L Linear: Index = Q. Abundance . e
                    Index = Q. Abundance^ K .e
  where {\tt Q} and {\tt K} are parameters to be estimated, and
  e is a lognormally-distributed error.

8 Sprat in the North Sea

8.1 The Fishery

8.1.1 ACFM advice applicable for 2004 and 2005

ACFM advised that a catch of 257,000 t in 2004 would allow the SSB to remain near or above the long-term average. This was based on the historic relationship between survey and catch. From 2002 to 2005 the TAC set by management for Subarea IV (EU zone) and Division IIa (EU zone) has been 257,000 t.

8.1.2 Total landings in 2004

Landing statistics for sprat for the North Sea by area and country are presented in Table 8.1.1 for 1987–2004. As in previous years, sprats from the fjords of western Norway are not included in the landings for the North Sea. Landings from the fjords are presented separately (Table 8.1.2) due to their uncertain stock identity. Table 8.1.3 shows the landings for 1994–2003 by year, quarter, and area in the North Sea. The Norwegian vessels are not allowed to fish in the 2nd and 3rd quarter in the EU and the Norwegian zone and not allowed to fish in the Norwegian zone until the quota has been taken in the EU-zone.

The landings in 2004 were 194,000 t. This was an increase compared to the landings in 2003 (176,500 t.) and 2002 (143,600 t.). This increase was due to an increase in landings during the 4th quarter by the Danish fleet. Anecdotal information states that in November and December the sprat stock was not as widely spread as in previous years facilitating sprat catches without large by-catches of herring. The Norwegian fishery in 2004 was insignificant. Neither Denmark nor UK (England and Wales) took their quota in 2004. The Danish fishery took all catches in the second and third quarter.

No sprat by-catches were reported in the landings from the Norwegian or the Swedish small-meshed fishery targeted at sandeel and Norway pout.

The quarterly and annual distributions of catches by rectangle for Subarea IV are shown in Figures 8.1.1–8.1.2.

8.2 Biological Composition of the Catch

8.2.1 By-catches in the North Sea sprat fishery

Data on the species composition of the by-catch is given in Table 8.2.1. Only data on by-catch from the Danish fishery were available to the Working Group. In general, more than 80% of the catches consist of sprat and in 2004 close to 90% of the catch consisted of sprat. The amount of herring caught as by-catch in the sprat fishery in 2004 is less than 5% of the total catch. This herring by-catch is the lowest since 1999.

8.2.2 Catches in number

The estimated quarterly catch-at-age in numbers for the years 1995 to 2004 is presented in Table 8.2.2. Denmark provided age composition data of commercial landings in 2004 for third and fourth quarter. The catches in the first quarter was predominantly taken during January and assuming little or no growth during winter, Danish samples from December 2003 were used to raise the catches in quarter 1 2004, only adding a year to the age-groups. For the second quarter age-length keys from July have been applied to the actual length distributions. Danish samples were used to raise the catches from Norway, England and Wales.

1-ringer sprat dominates the catches over all the years although the relative importance does vary with year. 0-ringer sprat catches in 2004 were only slightly lower compared to 2003, however still being slightly above the average for the whole time period. The majority of the total sprat catches are taken during the fourth quarter.

8.2.3 Quality of catch and biological data

The sampling intensity for biological samples, i.e., age and weight-at-age, is given in Table 8.2.4. The sampling level in 2004 is lower than in previous years. In Denmark the provisions in the EU regulation 1639/2001 have been implemented. This provision requires 1 sample per 2000 tonnes landed. This sampling level is lower than the guidelines (1 sample per 1000 tonnes) previously used by the HAWG, but as the fishery was carried out in a limited area and a limited season, the recommended sampling level can be regarded as adequate.

The Danish monitoring schemes for management purposes for species composition in the Danish small-meshed fisheries has worked well in 2004. A total of 834 samples were collected from landings taken in the North Sea by Danish vessels. The sampling figure for 2003 was 900 samples. The total landings from the Danish small mesh fishery in 2004 were 531,924 t (all species) compared to 506,000 t in 2003. This small increase is mainly due to changes in the sandeel fishery. The recommended sampling levels for species composition were achieved. The species composition in the Danish sprat fishery is shown in Table 8.2.1.

8.3 Fishery-independent information

The acoustic surveys for the North Sea Herring in June-July have estimated sprat abundance since 1996. In June-July 1998, sprat was mainly detected west of 1°W (R/V Tridens) (Simmonds et al, 1999). The acoustic estimates of sprat biomass in 1996-1998 were in the range of 40,000 t to 210,000 t. In 1999 the acoustic estimate of sprat was very low. The low value was not thought to be representative mainly due to inappropriate coverage of the south-eastern area (ICES 2000/D:07), the area expected to have the highest abundance of sprat in the North Sea. In 2000 the survey was extended by 30 n.mi to the south and covered for the first time the south-eastern area considered to have the highest abundance of sprat in the North Sea. By doing so, the estimate of sprat increased significantly. This year, there are indications that an area with higher density was encountered further north than in 2003. The estimated number of sprat increased by nearly 80% compared to 2003. The total sprat biomass estimated for the North Sea, was 360,000 tonnes (ICES 2005/G:04). In the eastern - south eastern area of the North Sea small 0-group sprat (<5-6 cm) accounted for 34% of this years total abundance. This is the first time that 0-group sprat have been recorded by this survey since 1998. It is, however, not clear whether the component of 0-ringer is recruiting from autumn spawning sprat or from an early spring spawning component (ICES 2004/AFM:18). The length distribution indicates that only the largest of this age group have been sampled and the abundance of 0-group sprat is thus considered an underestimate.

8.4 Mean Weight-at-age and Maturity-at-age

Mean weights (g) at age in the catches during 2004 are presented by quarter in Table 8.2.3. The table includes mean weights-at-age for 1995-2003 for comparison.

During the Working Group in 2002, data on maturity and age were compiled from the Danish commercial catches during quarters 1, 3 and 4 in 2001. Data on maturity were provided from the German Acoustic surveys in June-July during 1996-2001. No other countries contributed with data on maturity. No new data on sprat maturity has been available since 2001 and thus the time-series was not updated during the Working Group 2005.

8.5 Recruitment

The IBTS (February) sprat indices (no. per hour) in IVb (sprat standard area) are used as an index of abundance. The historical data were revised in 1995 (ICES 1995/Assess:13) and 1999 (ICES 1999/ACFM:12). The IBTS Working Group redefined the sprat index to be calculated as an area weighted mean over means by rectangles for the entire North Sea sprat stock. Based on this, the IBTS WG asked ICES Secretariat to carry out new calculations in 2001 (ICES 2000/D:07), which are the ones used in the present report. The old and the revised IBTS index is available in the Working Group report from 2003 for comparison (ICES 2003/ACFM:17). The fishing method (gear) in the IBTS-survey was standardised in 1983 and the data series from 1984, are comparable. The IBTS-indices for 1984–2005 are shown in Table 8.5.1 for age groups 1–4, 5+ and total. The index of 1-group increased significantly and is the highest in the whole time-series. The total-abundance index is at the level of the highest in the whole time-series. This is driven by the high abundance of age group 1 (2004 year class). The old IBTS-indices are available in ICES 2001/ACFM:12.

The IBTS data by rectangle are given in Figure 8.3.1a-c for age groups 1, 2 and 3+. Age 1-group was again found to be concentrated in the south-eastern areas of Division IVb and Division IVc. The mean lengths (mm) of age group 1 by rectangle are presented in Figure 8.3.2.

8.6 State of the Stock

8.6.1 Data Exploration and Preliminary Modelling

Sprat is a relatively short-living species and the catches consisting mostly of 1 and 2 year-olds. In addition, there are difficulties in age reading resulting in unreliable estimates of numbers-at-age both from the surveys and the commercial catches. Given those limitations a data exploration using Catch-Survey Analysis (CSA) was carried out. The Catch-survey Analysis and the inputs, were described in the working group report in 2003 and 2004 (ICES 2003/ACFM:10 and ICES 2004/ACFM:18). The model assumes that the population consists of two stages: the recruits (preferably a single year class which corresponds to the 1 year-old) and the fully recruited ages (the 2+ group).

Model input data consisting of the time-series of catch numbers for each stage, mean weight for each stage in the stock at the start of the year and the 1st quarter IBTS index of abundance for the 1 year-old sprat and older than 2 years-old are shown in Table 8.6.1 Given low sampling levels in years previous to 1995 and low inter-annual fluctuations in weight-at-age, constant weight-at-age based on commercial data from the 1st quarter was assumed for the whole period (1984-2004). Reservations regarding the ability of the IBTS 1-year-old index to fully reflect strong and weak cohorts for sprat were expressed in previous Working Group reports (see ICES 1998/ACFM:14). Those were linked to difficulties in age reading and/or a possible prolonged spawning and recruitment season. Another problem identified in some surveys was related to large catches in small areas, which could have been very influential on the results.

In 2003 the Working Group examined the biomass and the 1 year-old index trajectories and concluded that the data suggests that observed fluctuations in overall biomass are related to a large extent to observed fluctuations in the 1 year-old index. This is to be expected in a population where the recruits account for a large proportion of the stock, so a model that takes into account recruitment in the dynamics, is required

CSA requires a value for the instantaneous rate of natural mortality (M) and a parameter *s* corresponding to the ratio of the survey catchability of the recruits to the fully recruited ages which are fixed externally. The value of natural mortality is based on predation mortality estimates from a multispecies VPA (ICES 2002 /D:04). Estimates of predation mortality at-age and 90% confidence intervals representing the variation over time of the M values from the MSVPA were presented in last years report (ICES 2004/ACFM:18).

Model fits for M=0.7 to the IBTS indices are shown in Figure 8.6.1. An observation-error only model which estimates catchability of the fully recruited stage by close-form solution $q_n = \exp(mean(Log(n_t/N_t)))$ was implemented. Numbers at the start of the year of fish >2-year-old in the first year of data and all the recruit numbers were estimated by least-squares minimisation. The recruits corresponding to the last year in the series were computed from the survey index and the recruitment catchability. The model is sensitive to the choice of the M and s parameters. Given the constraints of the model which in its present form does not allow variations of M over time the model was run for M = 0.7 and 0.8. The input data used by this working group is shown in Table 8.6.1. In the absence of data that would support an alternative value s was equated to 1. Model output is shown in Table 8.6.2 for M = 0.7.

The model does not fit well the high IBTS 2+ index in 1998 given a low recruitment index in 1997; this could be an example of a late recruitment scenario where IBTS underestimated total recruitment (Figure 8.6.1). Estimated numbers of recruits and fully recruited and total biomass are shown in Figure 8.6.2. Examination of the residuals suggests patterns in the fit to the recruits index, but less so in the case of the fully recruited. (Fig. 8.6.3). Confidence intervals for the parameters were estimated by means of non-parametric bootstrapping. Biomass point estimates and 95% confidence intervals are shown in Figure 8.6.4 for M=0.7 together with the estimated biomass for M=0.8. The biomass trajectory estimated by using M=0.8 falls close to the confidence intervals for M=0.7.

Results from a retrospective analysis are shown on Figure 8.6.5 suggesting a recent period of negative bias preceded by a long period where the biomass was revised upwards. The Working Group concluded that the retrospective bias was relatively small.

The WG still regards this present assessment as exploratory.

8.7 Projections of Catch and Stock

The Working Group in 2004 considered that previous SHOT-approach is inappropriate for a short-lived species like sprat. Therefore the projection was based on the results from CSA. Biomass projections for 2005 and 2006 assuming median recruitment in 2006 and assuming annual catches in 2005 and 2006 which corresponds to the same exploitation rate as in 2004. This is shown in Figure 8.7.1. The biomass trajectories suggest that the stock, depending on 2005 recruitment, would remain relatively stable under that level of exploitation.

A catch prediction for assessment year was provided in the past on the basis of a linear regression of catch versus IBTS estimated biomass. The results for 2005 are shown on Figure 8.7.2 and corresponds to a catch for 2005 of 244 000 t (agreed TAC for 2005 is 257 000 t).

8.8 Quality of the Assessment

Trends in the mean weights-at -age during the first quarter used to compute the biomass index from the IBTS was reviewed in 2004. No trend was observed in the mean weights-at-age over time, therefore an average over all the years was used to compute stock biomass using the Catch Survey Analysis. The model fits time-series of abundance for 2 stages in the stock: the recruits and the fully recruited to the fishery. The IBTS indices for the 1st quarter were used as indicators. The Working Group is aware of problems associated with sprat in the IBTS (February) which may have hatched in autumn. However examination of the residuals from the model fit suggests that the problem results in additional noise in the data but the model still attains a reasonably good fit to the data. The results are sensitive to the value assumed for the catchability ratio *s*, the estimated biomass being scaled accordingly. Therefore, when examining the model output, emphasis should be placed on stock trends rather than on absolute values until an independent estimate of *s* becomes available.

Given the dynamics of this short-living species recent estimates of biomass are likely to correspond to the trajectories derived from M=0.7. Likewise, a value of s=1 for IBTS is compatible with perceptions that catchability of recruits is no different from the one of the fully recruited. The Working Group agreed that an approach like CSA seemed a promising tool to assess sprat in the North Sea. Further, the method, although not specifically designed for short-lived species, does show potential for assessment in that context and therefore it is recommended that the Working Group of Methods again considers assessment methods for short-lived species in the light of recent developments.

8.9 Management Considerations

The sprat stock shows signs of being in good conditions as the biomass appears to be increasing. One of the highest IBTS (February) 1-gr indices in the time series is seen in the 2005-indices recruiting to the 2005 fishery. The fishery in a given year is very dependent on that year's incoming year class; therefore a catch projection for 2005 assuming average recruitment is meaningless. Despite the short-comings of the exploratory assessment presented here there are indications that the stock is lightly exploited.

There are indications that larvae from autumn spawning will over-winter as larvae and metamorphose the year after. Therefore, better knowledge of spawning seasons and recruitment from a possible autumn spawning is required.

Table 8.1.1. Sprat in the North Sea. Catches (' 000 t) 1987-2004. Catch in fjords of western Norway excluded. (Data provided by Working Group members except where indicated). These figures do not in all cases correspond to the official statistics and cannot be used for management purposes.

Samples are not comparable to biological sampling tables for herring as many samples are from by-catch of sprat in other fisheries.

9 Sprat in Divisions VIId,e

9.1 The fishery

9.1.1 ACFM advice applicable for 2004

The TAC for this fishery was set to 9,600 t for 2003, 2004 and for 2005. No ACFM advice has been provided in recent years.

9.1.2 Catches in 2003

Table 9.1.1 shows the nominal landings in 1985–2004. The landings in 2004, as reported by UK (England and Wales) decreased and were the lowest for the period. Monthly catches for the Lyme Bay sprat fishery in the period from 1991 to 2002 are shown in Table 9.1.2. For 2003-2004 catch data per quarter were available to the working group.

9.1.3 Catch Composition

No data for the period 1999-2003 have been available to the working group. Data on catch compositions and the mean weights for 1991–1998, can be seen in the 2004-report (ICES 2004/ ACFM.18).

10 Sprat in Division IIIa

10.1 The Fishery

10.1.1 ACFM advice applicable for 2004 and 2005

The ACFM advice on sprat management is that exploitation of sprat will be limited by the restrictions imposed on fisheries for juvenile herring. This is a result of sprat being fished mainly together with juvenile herring. The sprat fishery is controlled by by-catch ceilings of herring as well as by-catch percentage limits. No ACFM advice on sprat TAC has been given in recent years. The sprat TAC for 2004 was 50,000 t, with a restriction on by-catches of herring not exceeding 21,000 t. For 2005 the same value of TAC was set, with a restriction of a by-catch ceiling of herring of 24,150t has been set for the EU fleet. This was based on scientific information regarding the prevailing abundance of herring in relation to sprat in Div. IIIa.

10.1.2 Landings

The total landings for Division IIIa by area and country are given in Table 10.1.1 for 1974 - 2004. The total landings increased by 33% from 2003 to 2004. This increase in landings was from Skagerrak where the total landings were doubled from 5,600 t to 11,800 t. In Kattegat, the landings were approximately at the same level as in 2003. The Norwegian and Swedish landings include the coastal and fjord fisheries.

Landings by countries and by quarter are shown in Table 10.1.2. There were landings taken in all quarters. Approximately 50% of the total catch was taken in the 4th quarter. Only minor landings were taken in the 2nd. Denmark has a total ban on the sprat fishery in Division IIIa from May to September.

The Danish monitoring schemes for management purposes for species composition in the Danish small-meshed fisheries has worked well in 2004. A total of 293 samples were collected from landings taken in Division IIIa by Danish vessels. The sampling figure for 2003 was 309 samples. The total landings from the Danish small mesh fishery in 2004 were 52,100 t (all species) compared to 52,600 t in 2003.

10.1.3 Fleets

Fleets from Denmark, Norway and Sweden carry out the sprat fishery in Division IIIa.

The Danish sprat fishery consists of trawlers using a 16 mm-mesh size codend and all landings are used for fishmeal and oil production. Some of the sprat landings from Denmark and Sweden are by-catches in the herring fishery using 32 mm mesh-size cod ends.

There is a Swedish fishery directed at sprat with by-catches of herring. There is also a fishery carried out with small purse seiners at the West Coast of Sweden for human consumption.

The Norwegian sprat fishery in Division IIIa is a coastal purse seine fishery for human consumption.

10.2 Biological Composition of the Catch

10.2.1 Catches in number and weight-at-age

The numbers and the mean weight-at-age in the landings from 1995 to 2004 are presented in Table 10.2.1 and Table 10.2.2, respectively. Landings, for which samples were collected, were raised using a combination of Swedish and Danish samples, without any differentiation in

types of fleets. Quarterly and annual distributions of catches by rectangle are shown in Figures 8.1.1–8.1.2.

10.2.2 Quality of catch and biological data

In 2004 Denmark has provided biological samples from all the quarters where there were landings. Sweden provided biological samples from 1st and 4th quarter in Skagerrak and only one in the 4th quarter in Kattegat. No Norwegian samples were collected. The required level of one sample per 1,000 t landed was more than met in 2004 with 59 samples from a total landing of 14,390 tonnes.

The samples were used to estimate the numbers of sprat-at-age and the mean weight-at-age, in all sprat landings (Tables 10.2.1 and Table 10.2.2 respectively). The sample size (71 samples) has decreased compared to the level in 2003 (87 samples). Thus the decrease in sampling level, the level is more than adequate. As in previous years, no samples of sprat were taken from the fisheries for human consumption. Therefore, data from the industrial landings were used for the estimation of numbers of sprat-at-age and the mean weight-at-age. Details on the sampling for biological data per country, area and quarter are shown in Table 10.2.3.

10.3 Fishery-independent information

Acoustic estimates of sprat have been available from the ICES co-ordinated Herring Acoustic surveys in Div. IIIa since 1996. In 1996 the total estimate was 7.9 x 10⁸ fish or 14,267 tonnes. About 95 % of the biomass was recorded in Kattegat. There were very low estimates of sprat from 1997 to 2002, but the estimates increased to 15,000 tonnes in 2003. In 2004 the abundance was estimated to be 1,090 million individuals or 15,000 tonnes. Again sprat was only encountered in the south eastern Kattegat (ICES CM 2005/G:04). No sprat has been reported from the survey in Skagerrak in the last years.

10.4 Mean weight-at-age

Mean weights-at-age (g) in the catches during 2004 are presented, by quarter, in Table 10.2.2. The table includes mean weights-at-age for 1995-2003 for comparison. These have been very variable over time, but whether this is due to actual variation in mean weight or difficulties in ageing of sprat is uncertain.

10.5 Recruitment

The IBTS (February) sprat indices for 1984-2005 are presented in Table 10.5.1. The IBTS data are provided by rectangle in Figure 8.3.1 for age groups 1, 2 and 3+, and the mean length (mm) of 1-ringer sprat in Figure 8.3.2. The indices are calculated as mean no./hr (CPUE) weighted by area where water depths are between 10 and 150 m (ICES 1995/Assess:13). The indices were revised in 2002 (ICES 2002/ACFM:12) based on an agreement in the IBTS WG in 1999, where it was decided to calculate the sprat index as an area weighted mean over means by rectangles for the IIIa (ICES 1999/D:2). The old time-series of IBTS indices (from 1984-2001) is shown in ICES 2001/ACFM:10.

The total IBTS index for 2005 is much higher than the total index in 2004, and the second highest since 1996. In 2004 all the indices were among the lowest for the period. The 1-group and the 2+ indices in 2005 are well above the average for the period 1984-2004. The procedure for the 2005 survey did not differ from previous years. The indices does not fully reflect strong and week cohorts in sprat. This was also expressed in previous working group report (ICES 1998 ACFM :14). This can still be linked to difficulties in age determination

10.6 State of the Stock

No assessments of the sprat stock in Division IIIa have been presented since 1985 and this year is no exception. A Schaefer model was fit to the data in 1999 (ICES 1999/ACFM:12) but that attempt was not successful and was subsequently abandoned. In 2003 the Working Group agreed to explore the data for sprat in Division IIIa by means of Catch-Survey Analysis (CSA) as performed for sprat in the North Sea (ICES 2003/ACFM:17). This was re-done this year with the time series 1995-2004. The mean weights used for recruitment and fully recruited, were the same as used for the North Sea. There is a pattern in the residuals with a negative trend in the 1-group but they are small values. The estimated biomass for 2004 was about 900,000 tonnes which is considered very high for the area. It also contradict biomass estimates from the acoustic survey and the exploratory SHOT-estimate. This suggests that there may be a scaling problem with in the model which has not been solved by the working group.

The signal in the IBTS (February)-index for 2005, is an increase in the sprat stock from last year and appears to be at a level above the average for the time-series 1984-2004.

10.7 Projection of Catch and Stock

There is no relationship between the IBTS (February) index (no./h) and the total catch in the same year and the index was not considered useful for management of sprat in Division IIIa.

The estimated yield for 2005 using the total IBTS index was at the level of 30,000 tonnes (Table 10.6.1) in a SHOT-estimate (Shepherd, 1991). This is one of the highest estimated yield for the period; however, this method is not considered to provide any reliable projection under the present management regime and the IBTS index is poor for this particular stock (Figure 10.7.1).

10.8 Reference Points

There are no reference points for this stock.

10.9 Management Considerations

Sprat in Division IIIa is short-lived with large inter-annual fluctuations in stock biomass. The natural inter-annual variability in stock abundance, mainly driven by recruitment variability, is high and does not appear to be strongly influenced by the observed levels of fishing effort.

The sprat has mainly been fished together with herring, except for 1994 and 1995 when a directed sprat fishery was carried out with low by-catches of herring. The human consumption fishery takes only a minor part of the total catch. With the current management regime, where there is a by-catch ceiling limitation of herring as well as by-catch percentage limits, the sprat fishery is controlled by these factors. Attempts to assess this stock have demonstrated the need for:

- Development of a suitable biomass index
- Improvement of the ageing techniques

There is also a need for better knowledge of spawning seasons and possible recruitment from the North Sea stock.

Table 10.1.1 Division Illa sprat. Landings in ('000 t) 1974-2004. (Data provided by Working Group members). These figures do not in all cases correspond to the official statistics and cannot be used for management purposes. In the period from 1982 to 1992 Sweden only reported total catches from division Illa.

11 Working Documents

- The spawning origin of herring in the Dutch catches from 2003 to 2004. Mark Dickey-Collas, Cindy van Damme, Lotte Worsøe Clausen.
- 2. Dutch discard programme. Olvin van Keeken
- 3. The current state of knowledge on the ecology and interactions of North Sea herring within the North Sea ecosystem. Mark Dickey-Collas
- 4. ICES coordinated acoustic survey of ICES divisions IIIa, IVa, Ivb, IVc AND VIa (North) 2004 Results. John Simmonds
- 5. Spatial Distribution of the German Pelagic Freezer Trawler Fleet's Activity in 2003 and 2004 obtained by VMS. Jens Ulleweit, Christopher Zimmermann
- 6. Herring Discards in the German Pelagic Freezer Trawler Fleet in 2004. Kay Panten, Jens Ulleweit, Christopher Zimmermann
- HAWG Definitions for the new ICES InterCatch Database. Christopher Zimmermann
- 8. Report of the herring larvae surveys in the North Sea in 2004/2005. Norbert Rohlf, Joachim Gröger
- 9. Fisheries & Stock assessment data in the Western Baltic in 2004. Tomas Gröhsler
- 10. A Two-Stage Biomass model given additional variance in the recruitment index. Beatriz Roel, Jose De Oliveira
- 11. The EU-Project HERGEN. Dorte Bekkevold
- 12. An Initial analysis of Harvest Control Rules for VIa north herring: Sensitivity to S/R relationships and management options. John Simmonds, Stephen Keltz
- 13. Present State of the EU-Project WESTHER on Separation of Western Herring Stocks. Emma Hatfield, Christopher Zimmermann
- 14. Informative diagrams on the quality of both analytic and historic retrospective assessments. Guus Eltink, Mark Dickey-Collas
- 15. Exchange of photos for determination of maturity stages in herring. Else Torstensen
- 16. Report of the Workshop on age readings of sprat, 14-17 December 2004. Else Torstensen
- 17. Report of the Acoustic survey of herring in VIaS and VIIbc in 2004. Karen Griffin, Maurice Clarke
- 18. Report of Celtic Sea Acoustic survey 2004. Ciaran O'Donnell, Karen Griffin, Maurice Clarke, Deirdre Lynch, Jenny Ulgren, Lonneke Goddijn, David Wall, Mick Mackey
- 19. Sampling and fishery dependent data for herring in Ireland in 2004. John Boyd, Maurice Clarke, Deirdre Lynch, Liz McArdle, John Molloy, Niamh Slattery, David Stokes
- 20. An exploration of the Irish Groundfish Survey as a recruit index for Celtic Sea herring. Graham Johnston, Maurice Clarke
- 21. The Production of Herring. Mark Dickey-Collas, Richard Nash
- 22. Preliminary investigation of the Dynamics of North Sea herring using SURBA, a survey only stock assessment model. John Simmonds
- 23. Survey indices of abundance for herring in the Irish Sea (Area VIIaN): 1992 2004. Beatriz Roel
- 24. Comparison of North Sea herring management 1962 to 1978 and 1987 to 2003. John Simmonds
- 25. MIK distributions and hydrography. Peter Munk
- 26. Proposed population management units and supporting data collection needs. Emma Hatfield, Dorte Bekkevold, John Simmonds

Appendix 2 - Stock Annex

Quality Handbook

ANNEX: hawg-her47d3

Stock specific documentation of standard assessment procedures used by ICES.

Stock: North Sea Autumn Spawning Herring

(NSAS)

Working Group: Herring Assessment WG for the Area south

of 62°N

Date: 17 March 2005

Authors: C. Zimmermann (ed.), J. Dalskov, M.

Dickey-Collas, H. Mosegaard, P. Munk, J. Nichols, M. Pastoors, N. Rohlf,

E.J. Simmonds, D. Skagen

A. General

A.1. Stock definition: Autumn spawning herring distributed in ICES area IV, Division IIIa and VIId. Mixing with other stocks occurs especially in Division IIIa (with Western Baltic Spring Spawning herring).

A.2. Fishery

North Sea Autumn Spawners are exploited by a variety of fleets, ranging from small purse seiners to large freezer trawlers, of different nations (Norway, Denmark, Sweden, Germany, The Netherlands, Belgium, France, UK, Faroe Islands). The majority of the fishery takes place in the Shetland-Orkney area in the 2nd and 3rd quarter, and in the English Channel (Division VIId) in the 4th quarter. Juveniles are caught in Division IIIa and as by-catch in the industrial fishery in the central North Sea. For management purposes, 4 fleets are currently defined: Fleet A is harvesting herring for human consumption in IV and VIId, but includes herring by-catches in the Norwegian industrial fishery; fleet B is the industrial (small mesh, <32 mm mesh size) fleet of EU nations operating in IV and VIId. North Sea Autumn spawners are also caught in IIIa in fleets C (human consumption) and D (small mesh).

A.3. Ecosystem aspects:

Herring is the key pelagic species in the North Sea and is thus considered to have major impact as prey and predator to most other fish stocks in that area.

The North Sea is semi-enclosed and situated on the continental shelf of North-western Europe and is bounded by England, Scotland, Norway, Sweden, Denmark, Germany, the Netherlands, Belgium and France. It covers an area of 745,950 km² of which the greater part is shallower than 200 m. It is one of the most diverse coastal regions in the world, with a variety of coastal habitats (fjords, estuaries, deltas, banks, beaches, sandbanks and mudflats, marshes, rocks and islands), and four ecological seasons. It is a highly productive (>300 gC m⁻² yr⁻¹) ecosystem but with primary productivity varying considerably across the sea. The highest values of primary productivity occur in the coastal regions, influenced by terrestrial inputs of nutrients, and

in areas such as the Dogger Bank and tidal fronts. Changes observed in trophic structure are indicative of a trend towards a decreasing resilience of this ecosystem. This trend is partially a response to inter-annual changes in the physical oceanography of the North Atlantic.

Herring are an integral and important part of the pelagic ecosystem in the North Sea. As plankton feeders they form an important part of the food chain up to the higher trophic levels. Both as juveniles and as adults they are an important source of food for some demersal fish and for sea mammals. Over the past century the top predator, man, has exerted the greatest influence on the abundance and distribution of herring in the North Sea. Spawning stock biomass has fluctuated from estimated highs of around 4.5 million tonnes in the late 1940s to a lows of less than 100,000 tonnes in the late 1970s. The species has demonstrated a robustness in relation to recovery from such low levels once fishing mortality is curtailed in spite of recruitment levels being adversely affected.

Their spawning and nursery areas, being near the coasts, are particularly sensitive and vulnerable to anthropogenic influences. The most serious of these is the ever increasing pressure for marine sand and gravel extraction. This has the potential to seriously damage and destroy the spawning habitat and disturb spawning shoals and destroy spawn if carried out during the spawning season. Similarly, trawling at or close to the bottom in known spawning areas can have the same detrimental effects. It is possible that the disappearance of spawning on the western edge of the Dogger bank could well be attributable to such anthropogenic influences.

In more recent years the oil and gas exploration in the North Sea has represented a potential threat to herring spawning although great care has been taken by the industry to restrict their activities in areas and at times of known herring spawning activity.

By-catch and Discard

By-catch consists of the retained 'incidental' catch of non-target species and discard is a deliberately (or accidentally) abandoned part of the catch returned to the sea as a result of economic, legal, or personal considerations. This section therefore deals with these two elements of the fishery, looking specifically at fishery-related issues. Cetacean, seabird and other threatened, rare and iconic species which may form part of a by-catch are considered separately in the next section.

Incidental Catch: The incidental catch of non-target species in the North Sea pelagic herring fishery in general is considered to be low. A recent study (Pierce et al, 2002) investigated incidental catch from commercial pelagic trawlers over the period January to August 2001. The target species, herring, accounted for 98% by weight of the overall catch with an overall incidental catch of 2.3%. Mackerel, which are known to occur in mixed schools with herring in division IVa was the main by-catch species, accounting for 69% of by-catch by weight. Haddock (25.7% of by-catch by weight), horse mackerel *Trachurus trachurus* (4.8%) and whiting *Merlangius merlangus* (0.4%) were all present in samples. However, onboard sampling over 2002 by Scottish and German observers found substantial discards of herring, taken as by-catch in the mackerel fishery over the 3 rd and 4th quarters, after herring quotas had been exhausted.

Discards and slipping: The indications are that large-scale discarding is not widespread in the directed North Sea herring fishery. A number of direct-observer surveys have recently been conducted on Scottish and Norwegian pelagic trawlers, based on observation of 222 hauls catching 9,889 tonnes fish (Napier et al, 2002) over 2000 - 2002. The overall discard rate was 4.2%, although that from pelagic trawlers of 6.6% was substantially higher than that from pursers (0.6%). These discard rates were higher than the overall figure of 2.8% recorded in an earlier study (Napier et al, 1999) which were evenly distributed between pursers and trawlers. This indicates that the different discard rates between the different fishing types in the later study were more a function of fishing location and stock size compositions rather

than any gear-specific size selectivity. Some discarding, in the form of wastage (i.e. fish left meshed in the net or in the cod-end of trawls), was associated with almost all pelagic catches but the actual quantities of fish involved were low (2% of total discarded fish). In both studies by Napier et al., most of the observed discarding occurred through slipping, i.e. opening the net and releasing the fish before they were pumped on-board. This occurred when catch volumes were too small, or the size of fish was too small or the fish were poor in quality. For both pursers and trawlers 'poor' fish quality was a significant cause of discarding. The size of the catch was also a significant cause of discarding from trawlers, either because the catch was too small or too large, with boats either discarding a small proportion or all of the catch. The recent influence of strong herring year classes was apparent in the composition of discards with smaller, younger fish accounting for a high proportion of the fish discarded in 2001. However surveys on the reasons why vessels discarded fish showed that larger discarding events (i.e. those >500 kg) were equally likely to the fish being of poor quality (trawlers) or the catch exceeded the vessel's capacity or market requirements (pursers). No data on survival of discarded fish has been collected but it is considered likely that mortality rates will be significant.

Ecosystem Considerations. The incidental non-target fish catch by directed North Sea herring fisheries appears to be low (ca. 2%), mainly consisting of mackerel when fishing mixed shoals. This infers that the ecosystem level implications of incidental fish catches are negligible. The discard of unwanted herring, mostly in the form of high-grading to improve catch quality and grade sizes of fish between 2-4 years of age (see Section above) is also low, being around 3,250 tonnes (2000) and 750 tonnes (2001) for the Scottish and Norwegian and Scottish pursers and refrigerated seawater tank (RSW) pelagic trawlers operating in ICES division IVa. For both years, this was equivalent to about 10.4% by weight of the total landings. Of more concern are discards of herring from other pelagic fisheries, especially that for mackerel, where more substantial discarding of herring occurs when quotas for herring are exhausted. National reports to ICES over 1996 to 2002 suggest that total herring discards have varied between 1,500 tonnes to an unprecedented 17,000 tonnes in 2002 (reflecting onboard sampling by Scotland and Germany that observed substantial discards of herring in the mackerel fishery in the 3rd and 4th quarter in Division IVa (W)). Assuming a distribution and yield of the international mackerel fishery in IVa in 2002 to be similar to that in 2001, herring discards of all fleets could be as high as 50,000 t. This would increase the total catch in the North Sea by almost 15% and would certainly have an influence on the North Sea autumn spawning stock assessment and the perception of stock size. Discarding behaviour appears to have changed again in 2003, when herring TAC has been increased by 50%, and at the same time the mackerel TAC has been reduced by more than 5%.

Interactions with Rare, Protected or Icon Species: Interactions between the directed North Sea herring fishery with rare, protected or icon species are, in general, considered to be exceptional. Species which may interact with the fishery are considered below.

Cetacean by-catch: Since 2000, the Sea Mammal Research Unit (SMRU) of St. Andrew's University in Scotland, under contract to DEFRA, has carried out a number of surveys to estimate the level of by-catch in UK pelagic fisheries. SMRU, in collaboration with the Scottish Pelagic Fishermen's Association, placed observers on board thirteen UK vessels for a total of 190 days at sea, covering 206 trawling operations around the UK. To date, no cetacean by-catch has been observed in the herring pelagic fishery in the North Sea. There is currently an ongoing observer programme in the UK monitoring cetacean by-catch rates in pelagic trawl fisheries with results due at the end of September 2003 and it is understood that this confirms that cetacean by-catch by the pelagic trawl fishery is negligible (Northridge, pers. comm.). Pierce (2002) also reports that no by-catches of marine mammals were observed over 69 studies hauls and considers that the underlying rate for marine mammals in the pelagic fisheries

studies (pelagic trawls in IVa and VIa) is no more than 0.05 (i.e. five events per 100 hauls) and may well be considerably lower than this.

Other than the above, there are no reliable estimates of by-catch for pelagic trawl fisheries, though observations have been made and by-catch rates have been established for several fisheries. Kuklik and Skóra (2003) refer to a single record of a harbour porpoise (*Phocoena phocoena*) bycaught in a herring trawl in the Baltic. Observations in several other pelagic trawl fisheries were reported by Morizur et al. (1999) and Couperus (1997). All appear to agree that incidental catches of cetaceans in the Dutch pelagic trawl fishery are largely restricted to late-winter/early-spring in an area along the continental slope southwest of Ireland.

On 24 July 2003 the European Commission issued a proposal for a Council Regulation to address the problem of cetacean by-catch in various fisheries. For the North Sea (ICES IV) 5% of pelagic trawl fisheries would have to be monitored by observers. In the eastern channel 5% of pelagic trips would have to be monitored from April to November but 10% from December to March. The Commission has asked the Council to adopt this proposal by 1 July 2004.

Seal by-catch: The by-catch of seals in directed pelagic herring fishery in the North Sea is reported to be "very rare" (Aad Jonker, pers. comm.). Independent verification also confirms this to be so, with perhaps one animal being caught by the whole North Sea fleet a year (Bram Couperus (RIVO), pers. comm.). Northridge (2003) observed 49 seals taken in 312 pelagic trawl tows throughout UK waters and reports that the fishery in North-western Scotland has the highest observed seal by-catch levels of UK pelagic trawl fisheries, possible amounting to dozens per year. Although not confirmed, it was assumed that the majority were grey seal *Halichoerus grypus*. This species is mainly distributed around the Orkneys and Outer Hebrides – out of a UK population of 129,000, only around 7,000 and 5,900 are distributed off the Scottish and English North Sea coasts respectively (SCOS, 2002), and so by-catch rates in the North Sea are likely to be substantially less than off the NW Scottish coast. The eastern Atlantic population of the Grey seal is not considered to be threatened.

Other by-catch: Sharks are occasionally caught by pelagic trawlers in the North Sea, although this is rare with a maximum of two fish per trip (Aad Jonker, pers. comm.). Survival rates are apparently high, with sharks being released during or after the cod-end is being emptied. The species are unknown, although blue shark *Prionace glauca*, which preys primarily upon schooling fishes such as anchovies, sardines, herring, are known to have been caught by pelagic trawls off the SW English coast (Bram Couperus (RIVO), pers. comm.). Gannets (*Morus bassanus*), which frequently dive at and around nets, were observed by Napier et al. (2002) entangled in the nets but were not present in samples. Actual mortality rates of caught gannets have not been assessed in detail, and some have been observed alive after release from the gear. An extrapolation from observed mortalities corresponds to around 560 gannet deaths per year, although this is based on a relatively low sample frame. Seabird by-catch in the North Sea is considered to be comparatively rare compared to the NW Scotland where 1-3 birds may be caught, esp. in grounds off St. Kilda (Aad Jonker (former freezer trawler skipper), pers. comm.). RIVO observers in the North Sea only recorded one incident of seabird by-catch over 10 trips (Bram Couperus (RIVO), pers. comm.).

B. Data

B.1. Commercial catch:

Commercial catch is obtained from national laboratories of nations exploiting herring in the North Sea. Since 1999 (catch data 1998), these labs have used a spreadsheet to provide all necessary landing and sampling data, which was developed originally for the Mackerel Working Group (WGMHSA) and further adapted to the special needs of the Herring Assessment Working Group. The current version used for reporting the 2003 catch data was v1.6.4. The majority of commercial catch data of multinational fleets was provided on these spreadsheets

and further processed with the SALLOCL-application (Patterson, 1998). This program gives the needed standard outputs on sampling status and biological parameters. It also clearly documents any decisions made by the species co-ordinators for filling in missing data and raising the catch information of one nation/quarter/area with information from another data set.

Transparency of data handling by the Working Group. The current practice of data handling by the Working Group is that the data received by the co-ordinators is available in a folder called "archive". These high-resolution data are not reproduced in the report. The archived data contains the disaggregated dataset (disfad), the allocations of samples to unsampled catches (alloc), the aggregated dataset (sam.out) and (in some cases) a document describing any problems with the data in that year.

Current methods of compiling fisheries assessment data. The species co-ordinator is responsible for compiling the national data to produce the input data for the assessments. In addition to checking the major task involved is to allocate samples of catch numbers, mean length and mean weight-at-age to unsampled catches. There are at present no defined criteria on how this should be done, but the following general process is implemented by the species co-ordinators. Searches are made for appropriate samples by gear (fleet) area quarter, if an exact match is not available the search will move to a neighbouring area if the fishery extends to this area in the same quarter. More than one sample may be allocated to an unsampled catch, in this case a straight mean or weighted mean of the observations may be used. If there are no samples available the search will move to the closest non-adjacent area by gear (fleet) and quarter, but not in all cases.

The Working Group acknowledges the effort some members have made to provide "corrected" data, which in some cases differ significantly from the officially reported catches. Most of this valuable information is gathered on the basis of personal knowledge of the fishery and good relations between the scientist responsible and the fishermen. The WG is aware of the problem that this knowledge might be lost if the scientist leaves, and asks the national laboratories to ensure continuity in data provision. In addition the Working Group recognises and would like to highlight the inherent conflict of interest in obtaining details of unallocated catches by country and increasing the transparency of data handling by the Working Group. This issue will have to be carefully considered in light of any future development by ICES of a standard platform to store all fisheries disaggregated data, particularly with regard to confidentiality.

The WG considered the need of a **long-term data storage** for commercial catches and sampling, and the documentation of any primary data processing of these data. From 2000 on (catch data for 1999), the latest (consistency checked) versions of the input files together with standard outputs and a documentation of filling-in decisions made by the co-ordinators, ideally in the SALLOC-formats, are stored in a separate "archive" folder. This is updated annually, and the complete collection (which is supposed to be kept confidential as it will contain data on misreporting and unallocated catches) will be available for WG members on request. As there was very little historical information available, WG members were asked to provide as much as possible national catch and historical data sets in any available format which is then stored in a "~historic" folder within "Archive". They will be consistency checked and transferred into a database system as soon as this is available.

B.2. Biological

Catch-at-age data (catch numbers-at-age, mean weights-at-age in the catch, mean length-at-age) is derived from the raised national figures received from the national laboratories. The data is obtained either by market sampling or by onboard observers, and processed as de-

scribed above. For information on recent sampling levels and nations providing samples, see Sec. 2.2. of the most recent HAWG report.

Mean weights-at-age in the stock and proportions mature (maturity ogive) are derived from the June/July international acoustic survey (see next paragraph).

B.3. Surveys

B.3.1 Acoustic: ICES Co-ordinated Acoustic Surveys for herring in North Sea, Skagerrak and Kattegat

The ICES Coordinated acoustic surveys started in 1979 around Orkney and Shetland with first major coverage in 1984. An index derived from that survey has been used in assessments since 1994 with the time-series data extending back to 1989. The survey was extended to IIIa to include the overlapping Western Baltic spring spawning stock in 1989, and the index has been used with a number of other tuning indices since 1991. The early survey had occasionally covered VIa (North) during the 1980s and was extended westwards in 1991 to cover the whole of VIa (North) annually since 1991, and provides the only tuning index for VIa (North) herring, By carrying out the co-ordinated survey at the same time from the Kattegat to South of the Hebrides all herring in these areas are covered simultaneously, reducing uncertainly due to area boundaries as well as providing input indices to three distinct stocks. The surveys are co-ordinated under ICES Planning Group for Herring Surveys ICES PGHERS.

At present, six surveys are carried out during late June and July covering most of the continental shelf north of 52°N in the North Sea and to the west of Scotland to a northern limit of 62°N. The eastern edge of the survey area is bounded by the Norwegian and Danish, Swedish and German coasts, and to the west by the shelf edge between 200 and 400 m depth. The surveys are reported individually in the report of the planning group for herring surveys, and a combined report is prepared from the data from all surveys. The combined survey results provide spatial distributions of herring abundance by number and biomass at age by statistical rectangle; and distributions of mean weight and fraction mature at age.

The acoustic recordings are carried out using Simrad EK60, EK500 and EY500 38 kHz sounder echo-integrator with transducers mounted on the hull, drop keel or towed bodies. Further data analysis is carried out using either BI500, Echoview or Echoann software. The survey track is selected to cover the area giving a basic sampling intensity over the whole area based on the limits of herring densities found in previous years. A transect spacing of 15 nautical miles is used in most parts of the area with the exception of some relatively high density sections, east and west of Shetland, in the Skagerrak where short additional transects were carried out at 7.5 nmi spacing, and in the southern area where a 30 nmi transect spacing is used.

The following target strength to fish length relationships have been used to analyse the data:

herring $TS = 20 \log L - 71.2 dB$ $sprat \qquad TS = 20 \log L - 71.2 dB$ $gadoids \qquad TS = 20 \log L - 67.5 dB$ $mackerel \qquad TS = 21.7 \log L - 84.9 dB$

Data is reported through standardised data exchange format and combined at FRS Marine Lab Aberdeen. The exchange format currently holds information on the ICES statistical rectangle level, with at least one entry for each rectangle covered, but more flexible strata are accommodated by allowing multiple entries for abundance belonging to different strata. Data submitted consists of the ICES rectangle definition, biological stratum, herring abundance by

proportion of Autumn spawners (North Sea and VIa North) and Spring spawners (Western Baltic, age and maturity, and survey weight (survey track length). Data are be presented according to the following age/maturity classes: 1 immature (maturity stage 1 or 2), 1 mature (maturity stage 3+), 2 immature, 2 mature, 3 immature, 3 mature, 4, 5, 6, 7, 8, 9+. In addition to proportions at age data on mean weights and mean length are reported at age/maturity by biological strata. Data is combined using an effort weighted mean based on survey effort reported as number of nautical miles of cruise track per statistical rectangle. A combined survey report is produced annually. Apart from the Biomass index for 1-9+-ringers,mean weights at age in the catch and proportions mature are derived from the survey to be used in the NSAS assessment.

B.3.2 International Bottom Trawl Survey:

The International Bottom Trawl Survey (IBTS) started out as a Young Herring Survey (IYHS) in 1966 with the objective of obtaining annual recruitment indices for the combined North Sea herring stocks. It has been carried out every year since, and it was realized that the survey could provide recruitment indices not only for herring, but for roundfish species as well. Examination of the catch data from the 1st quarter IBTS showed that these surveys also gave indications of the abundances of the adult stages of herring, and subsequently the catches have been used for estimating 2-5+ ringer abundances. The surveys are carried out in 1st quarter (February) and in 3rd quarter (August-September) using standardized procedures among all participants. The standard gear is a GOV trawl, and at least two hauls are made in each statistical rectangle.

In 1977 sampling for late stage herring larvae was introduced at the IBTS 1st quarter, using Isaccs-Kidd Midwater trawls. These catches appeared as a good indicator of herring recruitment, however examination of IKMT performance showed deficiencies in its catchability for herring larvae, and a more applicable gear, a ring net (MIK) was suggested as an alternative gear. Hence, gear type was changed in the mid 90'ies, and the MIK has been the standard gear of the program since. This ring net is of 2 meter in diameter, has a long two-legged bridle, and is equipped with a black netting of 1.5 mm mesh size. Oblique hauls are made during night in at least two statistical rectangles.

Indices of 2-5+ ringer herring abundances in the North Sea (1st quarter). Fishing gear and survey practices were standardised from 1983, and herring abundance estimates of 2-5+ ringers from 1983 onwards has shown the most consistent results in assessments of these age groups. This series is used in North Sea herring assessment. The catches in DivisionIIIa is not included in this index. Table 2.3.3.1 in the HAWG report shows the time series of abundance estimates of 2-5+ ringers from the 1st quarter IBTS for the whole period.

Index of 1-ringer recruitment in the North Sea (1st quarter). The 1-ringer index of recruitment is based on trawl catches in the entire survey area, hence, all 1-ringer herring caught in Div IIIa is included in this index. Indices are calculated as an area weighted mean over means by ICES statistical rectangle, and are available for year classes 1977 to recent (Table 2.3.3.3 of HAWG report). The Downs herring hatch later than the other autumn spawned herring and generally appears as a smaller sized group during the 1st quarter IBTS. A recruitment index of smaller sized 1-ringers is calculated using the standard procedure, but solely based on abundance estimates of herring <13 cm (see discussion of procedures in earlier reports (ICES CM 2000/ ACFM:10, and ICES CM 2001/ ACFM:12).

MIK index of 0-ringer recruitment in the North Sea (1st quarter). The MIK catches of late stage herring larvae is used to calculate and 0-ringer index of autumn spawned herring in the North Sea. A flowmeter at the gear opening is used for estimation of volume filtered by the gear, and using this information together with information on bottom depth, the density of herring larvae per square meter is estimated. A mean herring density in statistical rectangles is

raised to mean within subareas, and based on areas of these subareas an index of total abundance is estimated (see also ICES 1996/Asses:10). The series of estimates for subareas as well as the total index are shown in the actual report's Table 2.3.3.4.

B.3.3. Larvae:

Surveys of larval herring have a long tradition in the North Sea. Sporadic surveys started around 1880, and available scientific data goes back to the middle of the 20th century. The coordination of the International Herring Larvae Surveys in the North Sea and adjacent waters (IHLS) by ICES started in 1967, and from 1972 onwards all relevant data are achieved in a data base. The surveys are carried out annually to map larval distribution and abundance. Larval abundance estimates are of value as relative indicators of the herring spawning biomass in the assessment.

Nearly all countries surrounding the North Sea have participated in the history of the IHLS. Most effort was undertaken by the Netherlands, Germany, Scotland, England, Denmark and Norway. A number of other nations have contributed occasionally. A sharp reduction in ship time and number of participating nations occurred in the end of the 1980s. Since 1994 only the Netherlands and Germany contribute to the larvae surveys, with one exception in 2000 when also Norway participated.

Larvae Abundance Index (LAI): The total area covered by the surveys is divided into 4 sub areas corresponding to the main spawning grounds. These sub areas have to be sampled in different given time intervals. The sampling grid is standardized and stations are approximately 10 nautical miles apart. The standard gear is a GULF III sampler or one of its national modifications. Newly hatched larvae less than 10 mm total length (11 mm for the Southern North Sea) are used in the index calculation. To estimate larval abundance, the mean number of larvae per square meter obtained from the Ichthyoplankton hauls is raised to rectangles of 30x30 nautical miles and the corresponding surface area. These values are summed up within the given unit and provide the larval abundance per unit and time interval.

Multiplicative Larval Abundance Index (MLAI): The traditional LAI and LPE (Larval Production Estimates) rely on a complete coverage of the survey area. Due to the substantial decline in ship time and sampling effort since the end of the 80s, these indices could not be calculated in their traditional form since 1994. Instead, a multiplicative model was introduced for calculating a Multiplicative Larvae Abundance Index (MLAI, Patterson & Beveridge, 1995). In this approach the larvae abundances are calculated for a series of sampling units. The total time series of data is used to estimate the year and sampling unit effects on the abundance values. The unit effects are used to fill unsampled units so that an abundance index can be estimated for each year.

Calculation of the linearised multiplicative model was done using the equation:

ln(Indexyear,LAI unit) = MLAIyear + MLAI_{LAI} unit + uyear, LAI unit

where MLAIyear is the relative spawning stock size in each year, MLAI_{LAI} unit are the relative abundances of larvae in each sampling unit and year, LAI unit are the corresponding residuals. The unit effects are converted such that the first sampling unit is used as a reference (Orkney/Shetland 01-15.09.72) and the parameters for the other sampling units are redefined as differences from this reference unit. The model is fitted to abundances of larvae less than 10 mm in length (11 mm for SNS). The MLAI is updated annually and represent all larval data since 1972. The time series is used as a biomass index in the herring assessment.

B.4. Commercial CPUE

Not used for pelagic stocks.

B.5. Other relevant data

B.5.1 Separation of North Sea Autumn Spawners and IIIa-type Spring Spawners

North Sea Autumn Spawners and IIIa-type Spring Spawners occur in mixtures in fisheries operating in Divisions IIIa and IVaE (ICES, 1991/Assess:15): mainly 2+ ringers of the Western Baltic spring-spawners and 0-2-ringers from the North Sea autumn-spawners, including winter-spawning Downs herring. In addition, several local spawning stocks have been identified with a minor importance for the herring fisheries (ICES, 2001/ACFM 12).

The method of separating herring in Norwegian samples, using vertebral counts as described in former reports of this Working Group (ICES 1990/ Assess:14) assumes that for autumn spawners, the mean vertebral count is 56.5 and for Spring spawners 55.80. The fractions of spring spawners (fsp) are estimated from the formula (56.50-v)/(56.5-55.8), where v is the mean vertebral count of the (mixed) sample with the restriction that the proportion should be one if fsp>=1 and zero if fsp<=0. The method is quite sensitive to within-stock variation (e.g. between year classes) in mean vertebral counts.

Experience within the Herring Assessment Working Group has shown that separation procedures based on size distributions often will fail. The introduction of otolith microstructure analysis in 1996-97 (Mosegaard and Popp-Madsen, 1996) enables an accurate and precise split between three groups, autumn, winter and spring-spawners; however, different populations with similar spawning periods are not resolved with the present level of analysis. Different stock components that are not easily distinguished by their otolith microstructure (OM), are considered to have different mean vertebral counts (vs) as, e.g., winter-spawning Downs herring: 56.6 (Hulme, 1995), and the small local stocks, the Skagerrak winter/springspawners: 57 (Rosenberg and Palmén, 1982). Further, the estimated stock specific mean vs count varies somewhat among different studies; North Sea: 56.5, Western Baltic Sea: 55.6 (Gröger and Gröhsler, 2001) and North Sea: 56.5, Western Baltic Sea: 55.8 (ICES 1992/H:5). Comparison between separation methods using frequency distributions of vertebral counts and otolith microstructure showed reasonable correspondence. Using this information the years from 1991 to 1996 was reworked in 2001, applying common splitting keys for all years by using a combination of the vertebral count and otolith microstructure methods (ICES, 2001/ACFM:12). From 2001 and onwards, the otolith-based method only has been used for the Division IIIa.

Different methods of identifying herring stocks in the Division IIIa and Subdivisions 22-24 were recently evaluated in a EU CFP study project (EC study 98/026). The study involved several inter-calibration sessions between microstructure readers in the different laboratories involved with the WBSS herring. After the study was finished a close collaboration concerning reader interpretations has been kept between the Danish and Swedish laboratories. Subsamples of the 2002 and 2003 Danish, Swedish, and German microstructure analyses were double-checked by the same Danish expert reader for consistency in interpretation. The overall impression is an increasingly good agreement among readers.

New molecular genetic approaches for stock separation are being developed within the EU-FP5 project HERGEN (EU project QLRT 200-01370). Sampling of spawning aggregations during spring, autumn and winter has been carried out in 2002 and in 2003 in Division IIIa and in the Western Baltic at more than 10 different locations. Preliminary results point at a substantial genetic variation between North Sea and Western Baltic herring.

After the introduction of otolith microstructure analysis in 1996 it was discovered that in the western Baltic a small percentage of the herring landings might consist of autumn-spawners

individuals. Before molecular genetic methods became available for Atlantic herring the existence of varying proportions of autumn spawners in Subdivisions 22-24 in different years was considered a potential problem for the assessment.

C. Historical Stock Development

Model used:

Details on input parameters and model setup for the final ICA assessment are presented in Table 2.6.2.1. of the most recent HAWG report. The assessment has the same set-up and basic assumption as the assessment that was carried out last year. Input data are given in Tables 2.6.2.2. The ICA program operates by minimising the following general objective function:

$$\sum_{\substack{a=0, y=1997\\ \lambda_a \in \mathbb{N}}} \lambda_c \left(C - \hat{C}\right)^2 + \sum_i \lambda_i \left(I - \hat{I}\right)^2 + \sum_i \lambda_i \left(R - \hat{R}\right)^2$$
 which is the sum of the squared differences for the catches (separable model), the indices

(catchability $\frac{1}{2} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}} \sqrt{\frac{1}{2}$

The final objective true took assessment assessment was:

$$\sum_{a=1,y=1989}^{a=9+,y=2002} \lambda_{a,acoust} (\ln(q_{a,acoust}.\hat{N}_{a,y}) - \ln(ACOUST_{a,y}))^2 +$$

** except for $\sum_{v=1977}^{v=1979} \lim_{mik} \text{ which runs from 1979 and } y^2 +$

with the following variables: $\sum_{\substack{y=2002\\ 3,\overline{y}}}^{y=2002} \lambda_{ssr} \left(\ln(\hat{N}_{gs}) - \ln \frac{\alpha S\hat{S}B_y}{\beta + S\hat{S}B_y} \right)^2$

D. Short-Term Projection

The short-term prediction method was substantially modified in 2002. Following the review by SGEHAP (ICES 2001/ACFM:22), which recommended that a simple multi-fleet method would be preferable, the complex split-factor method used for a number of years prior to 2002 has not been used since. The multi-fleet, multi-option, deterministic short-term prediction programme (MFSP) was accepted by ACFM and was developed further last year. It is intended to continue to use this programme in the future. The good agreement between predicted biomass for the actual year and SSB taken from the assessment for the most recent year one year after demonstrates that the current prediction procedure for stock numbers is working well. In 2004, the Working Group has included prediction of low maturation into projections for 2005 and expects to monitor growth and maturation of North Sea herring carefully in the future and when deemed necessary will include these changes in predictions in the future.

Model used: Age-structured model, by fleet and area fished

Software used: MFSP

Initial stock size: output from ICA

Maturity: average of the two most recent years used

F and M before spawning: 0.67 for both (assumes spawning starts around September)

Weight at age in the stock: from last year in assessment (already smoothed, see assessment data description)

Weight at age in the catch: average of last two years BY FLEET

Exploitation pattern:

Intermediate year assumptions: Status quo F

Stock recruitment model used: Recent average recruitment (arithmetic, recent 10 years) is used, (unless there is some strong reason for using something else, e.g. if SSB is very low, we may use a prediction from the stock-recruit relationship)

Procedures used for splitting projected catches:

There are 4 values input for this parameter:

- IBTS 1-ringer proportion in last assessment year (y) is used for 1-ringers in y
- b. IBTS 1-ringer proportion in y+1 is used for 1-ringers in y+1, AND for 0-ringers in y.
- GLM (between MIK index and IBTS 1-ringer proportion) is applied to MIK index in y+1 to predict proportion for 1-ringers in y+2, AND for 0-ringers in y+1

GLM, as in (c), is applied to the Average MIK index for 1981 to year y to predict proportion for 1-ringers in y+3 (not relevant), AND for 0-ringers in y+2 (relevant)

G. Biological Reference Points

There is a well functioning harvest control rule in place for this stock, and apart from B_{lim} , the current reference points are derived from this HCR. The target F in the HCR was adopted by ACFM as the F_{pa} , while the trigger point at which F should be reduced below the target is adopted as B_{pa} . The HCR was briefly revisited in 2004, and the results support the initial definitions of limits.

Reference points currently in use are: B_{lim} is 800 000 t (below this value poor recruitment has been experienced); B_{pa} be set at 1.3 mill. T (as part of a harvest control rule based on simulations); F_{lim} is not defined, F_{pa} be set at $F_{ages\ 0-1}=0.12$, $F_{ages\ 2-6}=0.25$ (as part of a harvest control rule).

H. Other Issues

H.1 Biology of the species in the distribution area

The herring (*Clupea harengus*) is a pelagic species which is widespread in its distribution throughout the North Sea. The herring's unique habit is that it produces benthic eggs which are attached to a gravely substrate on the seabed. This points strongly to an evolutionary history in which herring spawned in rivers and at some later date re-adapted to the marine environment. The spawning grounds in the southern North Sea are in fact located in the beds of rivers which existed in geological times and some groups of spring spawning herring still spawn in very shallow inshore waters and estuaries. Spawning typically occurs on coarse gravel (0.5-5 cm) to stone (8-15 cm) substrates and often on the crest of a ridge rather than hollows. For example, in a spawning area in the English Channel, eggs were found attached to flints 2.5-25 cm in length, where these occurred in gravel, over a 3.5 km by 400m wide strip.

As a consequence of the requirement for a very specific substrate, spawning occurs in small discrete areas in the near coastal waters of the western North Sea. They extend from the Shetland Isles in the north through into the English Channel in the south. Within these specific areas actual patches of spawn can be extremely difficult to find.

The fecundity of herring is length related and varies between approximately 10,000 and 60,000 eggs per female. This is a relatively low fecundity for teleosts, probably because, in evolutionary terms, the benthic egg is a potentially less hazardous phase of development compared with the planktonic egg of most other teleosts. The age of first maturity is 3 years old (2 ringers) but the proportion mature at age may vary from year to year dependent on feeding conditions. Over the past 15 years the proportion mature at age 3 years (2 ringers) has ranged from 47% to 86% and for 4 year old fish (3 winter ringers) from 63% to 100%. Above that age, all are considered to be mature.

The benthic eggs take about three weeks to hatch dependant on the temperature. The larvae on hatching are 6mm to 9mm long and are immediately planktonic. Their yolk sac lasts for a few days during which time they will begin to feed on phytoplankton and small planktonic ani-

mals. Their planktonic development lasts around three to four months during which time they are passively subjected to the residual drift which takes them to various coastal nursery areas on both sides of the North Sea and into the Skagerrak and Kattegat.

Herring continue to be mainly planktonic feeders throughout their life history although there are numerous records of them taking small fish, such as sprat and sandeels, on an opportunistic basis. Calanoid copepods, such as *Calanus*, *Pseudocalanus* and *Temora* and the Euphausids, *Meganyctiphanes* and *Thysanoessa* still form the major part of their diet during the spring and summer and are responsible for the very high fat content of the fish at this time.

In the past, herring age has been determined by using the annual rings on the scales. In more recent years the growth rings on the otolith have proved more reliable for age determination. Herring age is expressed as number of winter rings on the otolith rather than age in years as for most other teleost species where a nominal 1 January birthdate is applied. Autumn spawning herring do not lay down a winter ring during their first winter and therefore remain as '0' winter ringers until the following winter. When looking at year classes, or year of hatching, it must be remembered that they were spawned in the year prior to their classification as '0' winter ringers.

North Sea herring comprise both spring and autumn spawning groups but the major fisheries are carried out on the offshore autumn spawning fish. The spring spawners are found mainly as small discrete coastal groups in areas such as The Wash and the Thames estuary. Juveniles of the spring spawning stocks found in the Baltic, Skagerrak and Kattegat may also be found in the North Sea as well as Norwegian coastal spring spawners.

The main autumn spawning begins in the northern North Sea in August and progresses steadily southwards through September and October in the central North Sea to November and as late as January in the southern North Sea and eastern English Channel. The widespread but discrete location of the herring spawning grounds throughout the western North Sea has been well known and described since the early part of the 20 th Century. This led to considerable scientific debate and eventually to investigation and research on stock identity. The controversy centred on whether or not the separate spawning grounds represented discrete stocks or 'races' within the North Sea autumn spawning herring complex. Resolution of this issue became more urgent as the need for the introduction of management measures increased during the 1950's. The International Council for the Exploration of the Sea (ICES) encouraged tagging and other racial studies and a review of all the historic evidence to resolve this problem. The conclusions were the basis for establishing the working hypothesis that the North Sea autumn spawning herring comprise a complex of three separate stocks each with separate spawning grounds, migration routes and nursery areas, illustrated in the figure below.

The three stock units are:

- The Buchan or Scottish group which spawn from July to early September in the Orkney Shetland area and off the Scottish east coast. Nursery areas for fish up to two years old are found along the east coast of Scotland and also across the North Sea and into the Skagerrak and Kattegat.
- The Banks or central North Sea group, which derive their name from their former spawning grounds around the western edge of the Dogger Bank. These spawning grounds have now all but disappeared and spawning is confined to small areas along the English east coast, from the Farne Islands to the Dowsing area, from August to October. The juveniles are found along the east coast of England, down to the Wash, and also off the west coast of Denmark.
- The Downs group which spawns in very late Autumn through to February in the southern Bight of the North Sea and in the eastern English Channel. The drift of their larvae takes them

north-eastwards to nursery areas along the Dutch coast and into the German Bight (Burd 1985).

At certain times of the year, individuals from the three stock units may mix and are caught together as juveniles and adults but they cannot be readily separated in the commercial catches. As a consequence, North Sea autumn spawning herring have to be managed as a single unit.

A further complication is that juveniles of the North Sea stocks are found, outside the North Sea, in the Skagerrak and Kattegat areas and are caught in various fisheries there. The proportions of juveniles of North Sea origin, found in these areas varies with the strength of the year class, with higher proportions in the Skagerrak and Kattegat when the year class is good.

H.2 Historic stock development and history of the fishery

Over many centuries the North Sea herring fishery has been a cause of international conflict sometimes resulting in war, but in more recent times in bitter political argument. There have also been fundamental changes in the nature of the fisheries. These have been driven both by changes in catching power and in response to changes in market requirements, particularly the demand for fish meal and oil. Most of these changes have resulted in greater exploitation pressures that increasingly led to the urgent need to ensure a more rational exploitation of North Sea herring. Such pressures really began to exert themselves for the first time during the 1950's when the spawning stock biomass of North Sea autumn spawning herring fell from 5 million tonnes in 1947 to 1.4 million tonnes by 1957. That period also witnessed the decline and eventual disappearance of a traditional autumn drift net fishery in the southern North Sea.

The annual landings from 1947 through to the early 1960's were high, but stable, averaging around 650,000t. Over the period 1952-62 the high fishing mortality (F 0.4 ages 2-6) resulted in a rapid decline in the spawning stock biomass from around 5 million tonnes to 1.5 million tonnes. Recruitment over this period was reasonable, but there were fewer and fewer year classes present in the adult stock, a clear indication that the stocks were being over-fished and that they were also being impacted by the developing industrial fishery in the eastern North Sea.

This period witnessed the complete collapse of the historic East Anglian autumn drift net fishery, which was based entirely on the Downs stock moving south to the Southern Bight and eastern English Channel to spawn. The reasons for that failure have been attributed both to high mortality of the juveniles in the North Sea industrial fisheries, and to heavy fishing by bottom trawlers on the spawning concentrations, in the English Channel, during the 1950's. Such intensive trawling, on vulnerable spawning fish, not only generated a high mortality but also disturbed spawning aggregations, destroyed the spawn and damaged the substrate on which successful spawning depends.

Fishing mortality on the herring in the central and northern North Sea began to increase rapidly in the late 1960's and had increased to F1.3 ages 2-6, or over 70% per year of those age classes, by 1968. Landings peaked at over 1 million tonnes in 1965, around 80% of which were juvenile fish. This was followed by a very rapid decline in the SSB and the total landings. By 1975 the SSB had fallen to 83,500t although the total landings were still over 300,000t. At the same time, spawning in the central North Sea had contracted to the grounds off the east coast of England whilst spawning grounds around the edge of the Dogger Bank were no longer used. This heralded the serious decline and near collapse of the North Sea autumn spawning herring stock which led to the moratorium on directed herring fishing in the North Sea from 1977 to 1981.

International larvae surveys and acoustic surveys were used to monitor the state of the stocks during the moratorium. By 1980 these surveys were indicating a modest recovery in the SSB

from its 1977 low point of 52,000t. By 1981 the SSB had increased to over 200,000t. Prior to the moratorium there had been no control, other than market forces, on catches in the North Sea directed herring fishery. Once the fishery re-opened in 1981 the North Sea autumn spawning herring stock was managed by a Total Allowable Catch (TAC) constraint. It should be noted that the TAC was only applied to the directed herring fishery in the North Sea which exploited mainly adult fish for human consumption. Targeted fishing for herring for industrial purposes was banned in the North Sea in 1976 but there was a 10% by-catch allowance in the fisheries for other species, including the small meshed fisheries for industrial purposes, mainly for sprat. Following the re-opening of the now controlled fishery the SSB steadily increased, peaking at 1.3 million tonnes in 1989. Annual recruitment, measured as '0' group fish, was well above the longterm average over this period. The 1985 year class was the biggest recorded since 1960 and the third highest in the records dating back to 1946. Landings also steadily increased over this period reaching a peak of 876,000 tonnes in 1988. This resulted from a steady increase in fishing mortality to Fages 2-6 = 0.6 (ca. 45%) in 1985 and a high bycatch of juveniles in the industrial fisheries for sprat. Following a period of four years of below average recruitment (year classes 1987-91) SSB fell rapidly to below 500,000 tonnes in 1993. Fishing mortality increased rapidly averaging $F_{ages~2-6}$ =0.75 (ca. 52%) over the period 1992-95 and recorded landings regularly exceeded the TAC. The North Sea industrial fishery for sprat developed rapidly over this period with the annual catch increasing from 33,000 tonnes in 1987 to 357,000 tonnes by 1995. With the 10% by-catch limit as the only control on the catch of immature herring, there was a consequent high mortality on juvenile herring which averaged 76% of the total catch in numbers of North Sea autumn spawners over this period.

During the summer of 1991 the presence of the parasitic fungus *Ichthyophonus* spp was noted in the North Sea herring stock. All the evidence suggested that the parasite was lethal to herring and that its occurrence could have a significant effect on natural mortality in the stock and ultimately on spawning stock biomass. High levels of infection were recorded in the northern North Sea north of latitude 60°N whilst infection rates in the southern North Sea and English Channel were very low. Efforts were made to estimate the prevalence of the disease in the stock through a programme of research vessel and commercial catch sampling. This led to estimates of annual mortality up to 16% (Anon., 1993) which was of the same order as the estimate of fishing mortality at the time. It was recognised that the behavioural changes and catchability of infected fish affected the reliability of the estimate of prevalence of the disease in the population. The uncertainty about the effect on stock size varied between estimates of 5% to 10% and 20%. Continued monitoring of the progress of the disease showed that by 1994 the prevalence in the northern North Sea had fallen from 5% in 1992 to below 1% and confirmed that the infection did not appear to be spreading to younger fish. Ultimately it was concluded that the disease had caused high mortality in the northern North Sea during 1991 and subsequently declined to the point where by 1995 the disease induced increase in natural mortality was insignificant.

The increased fishing pressure during the first half of the 1990's and the disease induced increase in natural mortality led to serious concerns about the possibilities of a stock collapse similar to that in the late 1970's. Reported landings continued at around 650,000 tonnes per year whilst the spawning stock began to decline again from over 1 million tonnes in 1990. The assessments at that time were providing an over optimistic perception of the size of the spawning stock and, for example, it was not until 1995 that it was realised that the SSB in 1993 had already fallen below 500,000 tonnes. This was well below the minimum biologically accepted level of 800,000 tonnes (MBAL) which had been set for this stock at that time.

H.3 Management and ACFM advice

In 1996, the total allowable catches (TACs) for Herring caught in the North Sea (ICES areas IV and Division VIId) were changed mid-year with the intention of reducing the fishing mortality by 50% for the adult part of the stock and by 75% for the juveniles. For 1997, the regu-

lations were altered again to reduce the fishing mortality on the adult stock to 0.25 and for juveniles to less than 0.1 with the aim of rebuilding the SSB up to 1.1 million t in 1998.

According to the EU and Norway agreement adopted in December 1997, efforts should be made to maintain the SSB above the MBAL (Minimum Biologically Acceptable Level) of 800,000 tonnes. An SSB reference point of 1.3 million has been set above which the TACs will be based on an F=0.25 for adult herring and F=0.12 for juveniles. If the SSB falls below 1.3 million tonnes, other measures will be agreed and implemented taking account of scientific advice. Relevant parts of the agreement (last amended Dec. 2001) read:

- Every effort shall be made to maintain a level of Spawning Stock Biomass (SSB) greater than the Minimum Biological Acceptable Level (MBAL) of 800,000 tonnes.
- A medium-term management strategy, by which annual quotas shall be set for the directed fishery and for by-catches in other fisheries as defined by ICES, reflecting a fishing mortality rate of 0.25 for 2-ringers and older and 0.12 for 0-1ringers, shall be implemented.
- 3. Should the SSB fall below a reference point of 1.3 million tonnes, the fishing mortality rates referred under paragraph 2, will be adapted in the light of scientific estimates of the precise conditions then prevailing, to ensure rapid recovery of SSB to levels in excess of 1.3 million tonnes.
- 4. The recovery plan referred to above may, inter alia, include additional limitations on effort in the form of special licensing of vessels, restrictions on fishing days, closing of areas and/or seasons, special reporting requirements or other appropriate control measures.
- 5. By-catches of herring may only be landed in ports where adequate sampling schemes to effectively monitor the landings have been set up. All catches landed shall be deducted from the respective quotas set, and the fisheries shall be stopped immediately in the event that the quotas are exhausted.
- 6. The allocation of the TAC for the directed fishery for herring shall be 29% to Norway and 71% to the Community. The by-catch quota for herring shall be allocated to the Community.
- 7. The parties shall, if appropriate, consult and adjust management measures and strategies on the basis of any new advice provided by ICES including that from the assessment of the abundance of the most recent year class.
- 8. A review of this arrangement shall take place no later than 31 December 2004.
- 9. This arrangement entered into force on 1 January 2002.

Until 2002, the SSB has been below the precautionary level of 1.3 million tonnes (\mathbf{B}_{pa}), and since 1998 other measures taken have consisted of an adoption of a F_{2-6} of 0.2 and a $F_{0-1} < 0.1$ to allow the rebuilding of the spawning biomass to above \mathbf{B}_{pa} .

Since 2002, the SSB is considered to have been above \mathbf{B}_{pa} . From then on, ACFM gave fleetwise catch option tables for fishing mortalities within the constraints the EU-Norway management scheme.

H.4 Sampling of commercial catch

Sampling of commercial catch is conducted by the national institutes. HAWG has recommended for years that sampling of commercial catches should be improved for most of the stocks. In January 2002, a new directive for the collection of fisheries data was implemented for all EU member states (Commission Regulation 1639/2001). The provisions in the "data directive" define specific sampling levels. As most of the nations participating in the fisheries on herring assessed here have to obey this data directive, the definitions applicable for herring and the area covered by HAWG are given below:

AREA	SAMPLING LEVEL PER 1000 T CATCH		
Baltic area (IIIa (S) and IIIb-c)	1 sample of which	100 fish measured and	50 aged
Skagerrak (IIIa (N))	1 sample	100 fish measured	100 aged
North Sea (IV and VId):	1 sample	50 fish measured	25 aged
NE Atlantic and Western Channel ICES areas II, V, VI, VII (excluding d) VIII, IX, X, XII, XIV	1 sample	50 fish measured	25 aged

Exemptions to the above mentioned sampling rules are:

Concerning lengths:

- (1) the national programme of a Member State can exclude the estimation of the length distribution of the landings for stocks for which TACs and quotas have been defined under the following conditions:
 - (i) the relevant quotas must correspond to less than 5 % of the Community share of the TAC or
 - to less than 100 tonnes on average during the previous three years;
 - (ii) the sum of all quotas of Member States whose allocation is less than 5 %, must account for

less than 15 % of the Community share of the TAC.

If the condition set out in point (i) is fulfilled, but not the condition set out in point (ii), the relevant Member States may set up a coordinated programme to achieve for their overall landings the implementation of the sampling scheme described above, or another sampling scheme, leading to the same precision.

Concerning ages:

- (1) the national programme of a Member State can exclude the estimation of the age distribution of the landings for stocks for which TACs and quotas have been defined under the following conditions:
- (i) the relevant quotas correspond to less than 10~% of the Community share of the TAC or to

less than 200 tonnes on average during the previous three years;

(ii) the sum of all quotas of Member States whose allocation is less than 10 %, accounts for less than 25 % of the Community share of the TAC.

If the condition set out in point (i) is fulfilled, but not the condition set out in point (ii), the relevant Member States may set up a coordinated programme as mentioned for length sampling.

If appropriate, the national programme may be adjusted until 31 January of every year to take into account the exchange of quotas between Member States;

The HAWG reviewed the implementation of the new sampling regime for the EU countries in 2003. It was expected that the overall sampling level might be improved, and this was demonstrated e.g. for North Sea herring in 2002 and 2003. However, there is concern that the new regime may lead to a deterioration of sampling quality, because it does not assure an appropriate sampling of different métiers (each combination of fleet/nation/area and quarter). Given the diversity of the fleets harvesting most stocks assessed by HAWG, an appropriate spread of

sampling effort over the different métiers is more important to the quality of catch at age data than a sufficient overall sampling level. The EU data directive appears to not assure this. The WG therefore recommends that all metiers with substantial catch should be sampled (including by-catches in the industrial fisheries), that catches landed abroad should be sampled and information on these samples should be made available to the national laboratories.

H.5 Terminology

The WG uses "rings" rather than "age" or "winter rings" throughout the report to denominate the age of herring, with the intention to avoid confusion It should be observed that, for autumn spawning stocks, there is a difference of one year between "age" and "rings". HAWG in 1992 (ICES 1992/Assess:11) stated that

"The convention of defining herring age rings instead of years was introduced in various ICES working groups around 1970. The main argument to do so was the uncertainty about the racial identity of the herring in some areas. A herring with one winter ring is classified as 2-years-old if it is an autumn spawner, and one-year-old if it is a spring spawner. Recording the age of the herring in rings instead of in years allowed scientists to postpone the decision on year of birth until a later date when they might have obtained more information on the racial identity of the herring.

The use of winter rings in ICES working groups has introduced a certain amount of confusion and errors. In specifying the age of the herring, people always have to state explicitly whether they are talking about rings or years, and whether the herring are autumn- or spring spawners. These details tend to get lost in working group reports, which can make these reports confusing for outsiders, and even for herring experts themselves. As the age of all other fish species (and of herring in other parts of the world) is expressed in years, one could question the justification of treating West-European herring in a special way. Especially with the present trend towards multispecies assessment and integration of ICES working groups, there might be a case for a uniform system of age definition throughout all ICES working groups.

However, the change from rings to years would create a number of practical problems. Data files in national laboratories and at ICES would have to be adapted, which would involve extra costs and manpower. People that had not been aware of the change might be confused when comparing new data with data from old working group reports. Finally, in some areas (notably Division IIIa), the distinction between spring- and autumn spawners is still hard to make, and scientists preferred to continue using rings instead of years.

The Working Group discussed at length the various consequences of a change from rings to years. The majority of the Group felt that the advantages of such a change did not outweigh the disadvantages, and it was decided to stick to the present system for the time being."

The text table below gives an example for the correlation between age, rings and year class for the different spawning types in late 2002:

YEAR CLASS (AUTUMN SPAWNERS)	2001/2002	2000/2001	1999/2000	1998/1999
Rings	0	1	2	3
Age (autumn spawners)	1	2	3	4
Year class (spring spawners)	2002	2001	2000	1999
Rings	0	1	2	3
Age (spring spawners)	0	1	2	3

Stock Western Baltic Spring spawning herring (WBSS)

Working Group: Herring Assessment Working Group for the Area South

of 62° N

Date: 18.03.2004

Authors: M. Cardinale, J. Dalskov, T. Gröhsler, H. Mosegaard,

A. General

A.1. Stock definition

Herring caught in Division IIIa are a mixture of North Sea autumn spawners and Baltic spring spawners. Spring-spawning herring in the eastern part of the North Sea, Skagerrak, Kattegat and SDs 22, 23 and 24 are considered to be one stock.

Catches of herring in the Kattegat, the Skagerrak and the Eastern part of the North Sea are taken from a mixture of two main spawning stocks (ICES, 1991/Assess:15): mainly 2+ ringers of the Western Baltic spring-spawners and 0-2-ringers from the North Sea autumn-spawners, including winter-spawning Downs herring. In addition, several local spawning stocks have been identified with a minor importance for the herring fisheries (ICES, 2001/ACFM 12).

The method of separating herring in Norwegian samples, using vertebral counts as described in former reports of this Working Group (ICES 1991/ Assess:15) assumes that for autumn spawners, the mean vertebral count is 56.5 and for Spring spawners 55.80. The fractions of spring spawners (fsp) are estimated from the formula (56.50-v)/(56.5-55.8), where v is the mean vertebral count of the (mixed) sample with the restriction that the proportion should be one if fsp>=1 and zero if fsp<=0. The method is quite sensitive to within-stock variation (e.g. between year classes) in mean vertebral counts.

Experience within the Herring Assessment Working Group has shown that separation procedures based on size distributions often will fail. The introduction of otolith microstructure analysis in 1996-97 (Mosegaard and Popp-Madsen, 1996) enables an accurate and precise split between three groups, autumn, winter and spring-spawners; however, different populations with similar spawning periods are not resolved with the present level of analysis. Different stock components that are not easily distinguished by their otolith microstructure (OM), are considered to have different mean vertebral counts (vs) as, e.g., winter-spawning Downs herring: 56.6 (Hulme, 1995), and the small local stocks, the Skagerrak winter/spring-spawners: 57 (Rosenberg and Palmén, 1982). Further, the estimated stock specific mean vs count varies somewhat among different studies; North Sea: 56.5, Western Baltic Sea: 55.6 (Gröger and Gröhsler, 2001) and North Sea: 56.5, Western Baltic Sea: 55.8 (ICES 1992/H:5). Comparison between separation methods using frequency distributions of vertebral counts and otolith microstructure showed reasonable correspondence. Using this information the years from 1991 to 1996 was reworked in 2001, applying common splitting keys for all years by

using a combination of the vertebral count and otolith microstructure methods (ICES, 2001/ACFM:12). From 2001 and onwards, the otolith-based method only has been used for the Div. IIIa.

Different methods of identifying herring stocks in the Division IIIa and Subdivisions 22-24 were recently evaluated in a EU CFP study project (EC study 98/026). The study involved several inter-calibration sessions between microstructure readers in the different laboratories involved with the WBSS herring. After the study was finished a close collaboration concerning reader interpretations has been kept between the Danish and Swedish laboratories. Subsamples of the 2002 and 2003 Danish, Swedish, and German microstructure analyses were double-checked by the same Danish expert reader for consistency in interpretation. The overall impression is an increasingly good agreement among readers.

New molecular genetic approaches for stock separation are being developed within the EU-FP5 project HERGEN (EU project QLRT 200-01370). Sampling of spawning aggregations during spring, autumn and winter has been carried out in 2002 and in 2003 in Div. IIIa and in the Western Baltic at more than 10 different locations. Preliminary results point at a substantial genetic variation between North Sea and Western Baltic herring, but significant variation has also been found among spawning populations in DivIIIa and subdiv. 22-24.

For Subdivisions 22, 23 and 24 it is assumed that all individuals caught belong to the Western Baltic spring spawning stock.

After the introduction of otolith microstructure analysis in 1996 it was discovered that in the western Baltic a small percentage of the herring landings might consist of autumn-spawners individuals. Before molecular genetic methods became available for Atlantic herring the existence of varying proportions of autumn spawners in Subdivisions 22–24 in different years was considered a potential problem for the assessment.

Although local aggregations of winter and autumn spawning herring are found in the Western Baltic area these aggregations are genetically more closely related to the Western Baltic spring spawners than to the North Sea autumn spawners (HERGEN, EU project QLRT 200-01370). Therefore, with the present genetic perception in mind, when herring with otolith microstructure indicating autumn hatch are found in subdivisions 22-24 these are treated as belonging to the WBSS stock.

A.2. Fishery

The fleet definitions used since 1998 for the fishery in Div. IIIa are:

- **Fleet C**: directed fishery for herring in which trawlers (with 32 mm minimum mesh size) and purse seiners participate.
- **Fleet D**: All fisheries in which trawlers (with mesh sizes less than 32 mm) and small purse seiners, fishing for sprat along the Swedish coast and in the Swedish fjords, participate. For most of the landings taken by this fleet, herring is landed as by-catch.

Danish and Swedish by-catches of herring from the sprat fishery and the Norway pout and blue-whiting fisheries are listed under fleet D.

In SDs 22–24 most of the catches are taken in a directed fishery for herring and some as bycatch in a directed sprat fishery. All landings from SDs22–24 are treated as one fleet.

A.3. Ecosystem aspects

Applying new molecular genetic methods and results emerging from ongoing research projects on herring (HERGEN and WESTHER) the possibility of considering genetic diversity is within reach. Preliminary results indicate an increase in genetic distance between herring populations in the Baltic and successive populations in subdivisions 24, 22, 21, and 20 and

finally the North Sea where genetic distance reach a maximum constant difference to the Baltic. Further, genetic differences are larger among populations within the Divisions IIIa and Western Baltic than among populations in the North Sea.

B. Data

B.1. Commercial catch

The level of sampling of the landings for the human consumption fishery and the small-meshed fishery landings was generally acceptable in the Skagerrak, the Kattegat and SDs 22-24 during the last years. Where sampling was missing in areas and quarters on national landings, sampling from either other nations or adjacent areas and quarters were used to estimate catch in numbers and mean weight-at-age.

Based on the proportions of spring- and autumn spawners in the landings, number and mean weights by age and spawning stock are calculated.

The text table below the shows different input data provided by country:

		DATA			
Country	Caton (catch in weight)	Canum (catch-at-age in numbers)	Weca (weight-at-age in the catch)		
Denmark	x	X	x		
Germany	X	X	X		
Norway	X				
Poland	X	X	Х		
Sweden	X	x	x		

B.2. Biological

Mean weights-at-age in the catch in the 1st quarter were used as stock weights.

The proportions of F and M before spawning was assumed constant between years. F-prop was set to be 0.1 and M-prop 0.25 for all age groups.

Natural mortality was assumed constant at 0.2 for all years and 2+ ringers. A predation mortality of 0.1 and 0.2 was added to the 0 and 1 ringers, which resulted in an increase in their natural mortality to 0.3 and 0.5, respectively (Table 3.6.4). The estimates of predation mortality were derived as a mean for the years 1977–1995 from the Baltic MSVPA (ICES 1997/J:2).

The maturity ogive was assumed constant between years:

W-rings	0	1	2	3	4	5	6	7	8+
Maturity	0.00	0.00	0.20	0.75	0.90	1.00	1.00	1.00	1.00

B.3. Surveys

The summer Danish acoustic survey in Division IIIa is part of an annual survey covering the North Sea and Division IIIa in July-August. R/V DANA conducted the survey in Division IIIa. For each sub area the mean back scattering cross section was estimated for herring, sprat, gadoids and mackerel by the TS relationships given in the Manual for Herring Acoustic Surveys in ICES Division III, IV, and IVa (ICES 2002/G:02). Used in the final assessment.

The first joint acoustic survey was carried out with R/V 'Solea' in Subdivisions 22-24 in October 1987. Since 1989 the survey was repeated every year as a part of an international hydracoustic survey in the Baltic. Used in the final assessment.

The IBTS 3^{rd} quarter survey in Div. IIIa, which is a part of the North Sea and Div. IIIa bottom trawl survey that is carried out in the 1^{st} and 3^{rd} quarter. The IBTS has been conducted annually in the 1^{st} quarter since 1977 and 3^{rd} quarters from 1991. From 1983 and onwards the survey was standardised according to the IBTS manual (ICES 2002/D:03). During the HAWG 2002 the IBTS survey data (both quarter) were revised from 1991 to 2002. Historical catch rates are heavily skewed and therefore the survey indices by winter rings 1-5 were calculated as geometric means from observed abundances $(n \cdot h^{-1})$ at age at trawl stations. Used in the final assessment.

The German herring larvae monitoring started in 1977 and takes place every year from March/April to June in the main spawning grounds of the spring spawning herring in the Western Baltic. These are the Greifswalder Bodden and adjacent waters. For the calculation of the number of larvae per station and area unit, the methods of Smith and Richardson (1977) and Klenz (1993) were used and projected to length-classes. Further details concerning the surveys and the treatment of the samples are given in Brielmann (1989), Müller and Klenz (1994) and Klenz (2002). Used in the final assessment.

Appendix 4 - Stock Annex

Quality Handbook ANNEX: Herring in Celtic Sea and VIIj

Stock specific documentation of standard assessment procedures used by ICES.

Stock Herring in the Celtic Sea and VIIj

Working Group: Herring Assessment Working Group for the

area south of 62° N.

Date: 19th April 2004

A. General

A.1. Stock definition

The herring to the south of Ireland in the Celtic Sea and in Division VIIj comprise both autumn and winter spawning components. For the purpose of stock assessment and management, these areas have been combined since 1982. Spawning in VIIj has traditionally taken place in the autumn and in VIIg and VIIaS, later in the autumn and in the winter.

A.2. Fishery

In recent years, this fishery has been prosecuted entirely by Ireland. The fishing season is the same as the assessment period, 1st April to the 31st March the following year. The TAC is set on an annual basis, however.

In the past season season, the fishery was allowed to remain open throughout. This was to allow vessels to target fish outside the spawning seasons when the fish are of better quality and marketability. The spawning grounds are protected by rotating box closures implemented under EU legislation. In addition to these, one box was voluntarily closed in the recent seasons. This initiative was initiated by the Irish Southwest Pelagic Management Committee to afford extra protection to first time spawners. The Irish Southwest Pelagic Management Committee was established to manage the Irish fishery for this herring stock. This committee, therefore, has responsibility for management of the entire fishery for this stock at present.

Landings have decreased markedly in recent years from around 20,000 t in the 1997/1998 season to around 11,000 t in the 2003/2004 season. The fishery is currently prosecuted by Irish RSW pelagic trawlers and by Irish polyvalent trawlers using pelagic gear.

A.3. Ecosystem aspects

B. Data

B.1. Commercial catch

The commercial catches are provided by national laboratories belonging to the nations that have quota for this stock. In recent years, only Ireland has caught herring in this area, so catch-at-age, mean weights and stock weights are derived entirely from Irish sampling. Sampling is performed as part of commitments under the EU Council Regulation 1639/2001.

Commercial catch at age data are submitted in Exchange sheet v 1.6.4. These data are usually processed using SALLOCL. This program (Patterson, 1998). This program gives outputs on sampling status and available biological parameters and documents actions taken to raise unsampled metiers using other data sets. The species co-ordinator allocates samples of catch numbers, mean length and mean weight-at-age to unsampled catches using appropriate samples by gear (fleet) area quarter and if an exact match is not available then a neighbouring area if the fishery extends to this area in the same quarter.

B.2. Biological

Mean weights at age in the catch in the 4th and 1st quarter are used as stock weights. This is a new procedure first used in 2004, because much of the catch was taken in the summer, before the spawning period.

The natural mortality is based on the results of the MSVPA for North Sea herring.

B.3. Surveys

A series of acoustic surveys have been carried out on this stock from 1990-1996. The series was interrupted in 1997 due to the lack of the survey vessel, it was resumed in 1998. For the 2002/2003 season one acoustic survey was carried out to determine stock abundance. It was decided that a single survey carried out on fish approaching the grounds would be sufficient to contain the stock. A review of this survey series is in preparation (O'Donnell et al. in prep.).

B.4. Commercial CPUE

Not used for this stock.

B.5. Other relevant data

C. Historical Stock Development

Model used:

Recent WG's have used the results of the acoustic surveys in the ICA programme but stated that the results should be taken as minimum estimates.

Software used: The ICA package is used.

Model Options chosen:

The period of separable constraint is 6 years, with areference age of 3-ring. Terminal selection is fixed at 1.0. Reference F is calculated for 2-ring to 7-ring fish. Fish of 1-ring are down weighted by 0.1, all other ages are not down weighted.

The acoustic abundance estimates are included for ages 2-5 only (winter rings). The acoustic estimates are treated as a relative index, using a linear model.

Input data types	and	characteristics:
------------------	-----	------------------

ТүрЕ	NAME	YEAR RANGE	AGE RANGE	VARIABLE FROM YEAR TO YEAR YES/NO
Caton	Catch in tonnes	1958-2003	1-9	Yes
Canum	Catch at age in numbers	1958-2003	1-9	Yes
Weca	Weight at age in the commercial catch	1958-2003	1-9	Yes
West	Weight at age of the spawning stock at spawning time.	1958-2003	1-9	Yes

Tuning data:

Түре	Name	YEAR RANGE	AGE RANGE
Tuning fleet 1	CSHAS	1990-2003	2-5
Tuning fleet 2			
Tuning fleet 3			

D. Short-Term Projection

Model used: Multi fleet Deterministic Projection (Smith, 2000).

Software used: MFDP Software

A short-term projection is carried out under the following assumptions. The number of 1 ringers was based on the geometric mean from 1958 to 2001. This was followed to allow for the inclusion of the period of recruitment failure. This value was 406 million fish. Mean weights in the catch and in the stock were calculated as means over the period 1998-2003. Population numbers of 2-ringers in the 2004/2005 season was calculated by the degradation of geometric mean recruitment (1958-2001) using the equation, following the same procedure as last year.

$$N_{t+1} = N_t \, * \, e^{\text{-}F + M}$$

Following the same procedure as last year, two scenarios are presented, one based on \mathbf{F}_{sq} (= F_{2003}), the other on a catch constraint of 13,000 (the TAC for 2004).

E. Medium-Term Projections

Not performed

F. Long-Term Projections

Not performed

G. Biological Reference Points

 \mathbf{B}_{pa} is set at 44,000 t and \mathbf{B}_{lim} at 26,000 t. F reference points are not defined for this stock.

Appendix 5 - Stock Annex

Quality Handbook

Stock specific documentation of standard assessment procedures used by ICES.

Stock: Herring in VIa (North)

Working Group: Herring Assessment WG for the Area south

of 62°N

Date: 18 March 2004

Authors: E.M.C. Hatfield and E.J. Simmonds

A. General

A.1. Stock definition

The stock is distributed over ICES Division VIa (N). Some of the larger adults typically found close to the shelf break may be caught in division Vb.

A.2. Fishery

The dominant fleet fishing in VIa (N) since 1957 has been the Scottish fleet. In the early years the Scottish fishery was prosecuted using a mixture of vessel size and gear, including gill nets, ring-nets and trawls. The boats were small, and targeted the coastal stock, primarily fishing in the winter. Until 1970 the only other nations fishing in this area on a regular basis were the former German Federal Republic, and to a much lesser extend the Netherlands. These fleets operated in deeper water near the shelf edge.

In 1970 a large increase in exploitation occurred with the entry of fleets from Norway and the Faroes, and an increased Netherlands catch. In addition, considerably smaller catches were taken by France and Iceland.

Throughout this period juvenile herring catches from the Moray Firth, in the north-east of Scotland, were included in the VIa catch figures, as tagging programs showed there to be some links between herring spawning to the west of Scotland and the Moray Firth juveniles.

Prior to 1982 herring stocks in ICES Area VIa were assessed as one stock, along with the herring by-catch from the sprat fishery in the Moray Firth. In the 1982 herring assessment working group report, and in subsequent years, Area VIa was split into a northern and a southern area at 56°N (ICES, 1982).

In 1979 and 1981 the fishery was closed. After re-opening the nature of the fishery changed to an extent, with fewer Scottish boats targeting the coastal stock than before the closure. The Scottish domestic pair trawl fleet and the Northern Irish fleet operated in shallower, coastal areas, principally fishing in the Minches and around the Island of Barra in the south; younger herring are found in these areas. Since 1986 Irish trawlers have operated in the south of the area, from the VIa (S) line up to the south-western Hebrides. The Scottish and Norwegian purse seine fleets targeted herring mostly in the northern North Sea, but also operated in the northern part of VIa (N). An international freezer-trawler fishery operated in deeper water

near the shelf edge where older fish are distributed. These vessels are mostly registered in the Netherlands, Germany, France and England. In recent years the catch of these fleets has become more similar and has been dominated by younger adults resulting from increased recruitment into the stock.

In recent years the Scottish fleet has changed to a predominantly purse-seine fleet to a trawl fleet. Norwegian vessels fish less in the area than in the past. Scottish catches still comprise around half of the total, the rest is dominated by the offshore, international fishery.

A recent EU-funded programme WESTHER aims to elucidate stock structures of herring throughout the western seaboard of the British Isles using a combination of morphometric measurements, otolith structure, genetics and parasite loads. The results of this should provide the best-available information on mixing of stocks within and beyond VIa (N).

A.3. Ecosystem aspects

Herring in this area is an important food source for sea birds, sea mammals and many piscivorous fish.

Adult herring in VIa (N) can consume eggs of other fish species in the area. However, it has not been possible to demonstrate a relationship between herring abundance and recruitment to other stocks, and stomach investigations of herring do not indicate that the predation effect on eggs has significant impact on egg survival for other stocks.

B. Data

B.1. Commercial catch

Commercial catch is obtained from national laboratories of nations exploiting herring in VIa (N). Since 1999 (catch data 1998), these labs have used a spreadsheet to provide all necessary landing and sampling data, which was developed originally for the Mackerel Working Group (WGMHSA) and further adapted to the special needs of the Herring Assessment Working Group. The current version used for reporting the 2002 catch data was v1.6.4. The majority of commercial catch data of multinational fleets was provided on these spreadsheets and further processed with the SALLOCL-application (Patterson, 1998a). This program gives the needed standard outputs on sampling status and biological parameters. It also clearly documents any decisions made by the species co-ordinators for filling in missing data and raising the catch information of one nation/quarter/area with information from another data set.

Transparency of data handling by the Working Group. The current practice of data handling by the Working Group is that the data received by the co-ordinators is available in a folder called "archive". These high-resolution data are not reproduced in the report. The archived data contains the disaggregated dataset (disfad), the allocations of samples to unsampled catches (alloc), the aggregated dataset (sam.out) and (in some cases) a document describing any problems with the data in that year.

Current methods of compiling fisheries assessment data. The species co-ordinator is responsible for compiling the national data to produce the input data for the assessments. In addition to checking the major task involved is to allocate samples of catch numbers, mean length and mean weight-at-age to unsampled catches. There are at present no defined criteria on how this should be done, but the following general process is implemented by the species co-ordinators. Searches are made for appropriate samples by gear (fleet) area quarter, if an exact match is not available the search will move to a neighbouring area if the fishery extends to this area in the same quarter. More than one sample may be allocated to an unsampled catch, in this case a straight mean or weighted mean of the observations may be used. If there are no

samples available the search will move to the closest non-adjacent area by gear (fleet) and quarter, but not in all cases.

Until 2003 the VIa(N) catch data extended back to the early 1970s; since 1986 the series has run from 1976 to present. In 2004 the data set was extended back to 1957. Details are given below.

Historic Catches from 1957 to 1975

The working group has obtained preliminary estimates of catch and catch-at-age for the period 1957 to 1975. These have been estimated from records of catch presented in HAWG reports from 1973, 1974, 1981 and 1982. Intervening reports were also consulted to check for changes or updates during the period. Catch-at-age data were available from 1970 to 1975 from the 1982 Working Group report, and catches-at-age for the period 1957 to 1972 were estimated from paper records of catch-at-age by national fleets for 1957 to 1972, held at FRS Marine Laboratory Aberdeen. The fishing practices of national fleets were established for the period 1970 to 1980 from catches in VIa and VIa (N) recorded in the 1981 and 1982 Working Group reports respectively. This procedure suggested that, on average, more than 90% of catch by national fleet could be fully assigned to either VIa (N) or VIa (S). The remaining catch was assigned assuming historic proportions. During this period catches were split into autumn and spring spawning components; anecdotal information on trials to verify this separation suggests it was not a robust procedure. Currently about 5% of herring in VIa (N) is found to be spent at the time of the acoustic surveys in July, and thought to be spring spawning herring. However, at present the Working Group assesses VIa (N) herring as one stock, regardless of spawning stock affiliation. In the earlier period higher proportions were allocated as spring spawners. The Working Group considered that it was preferable to combine all catch in the earlier period as VIa (N) catch, as the spawning components are currently mixed and the historic separation was uncertain. Similarly, a small Moray Firth juvenile fishery was also included in VIa (N) catch in earlier years because it was thought that these juveniles were part of the VIa (N) stock. Separating this component in the historic data was difficult, and as the fishery ceased in the very early 70s this has no implications for current allocation of these fish. The Moray Firth is, geographically, part of IVa (ICES stat. rectangles 44E6, 44E7, 45E6) and is now managed as part of that area. Currently there are no juvenile herring catches from the Moray Firth. Full details of the analysis carried out is provided as an appendix (Appendix 11) to the 2004 Working Group report.

Allocation of catch and misreporting

This fishery had a strong tradition of misreporting. It is believed that the shortfall between the TAC and the catch was used to misreport catches from other areas (from IVa to the east and from VIa (S) to the south). In the past, fishery-independent information confirmed that large catches were being reported from areas with low abundances of fish, and informal information from the fishery and from other sources confirmed that most catches of fish recorded between 4°W and 5°W were most probably misreported North Sea catches. The problem was detailed in the Working Group report in 2002 (ICES 2002/ACFM:12). Improved information from the fishery in 1998 - 2002 allowed for re-allocation of many catches due to area misreporting (principally from VIa (N) to IVa (W)). This information was obtained from only some of the fleets

As a result of perceived problems of area misreporting of catch from IVa into VIa (N), Scotland introduced a new fishery regulation in 1997 aiming to improve reporting accuracy. Under this regulation, Scottish vessels fishing for herring are required to hold a license either to fish in the North Sea or in the west of Scotland area (VIa (N)). Only one of these options can be held at any one time.

The Working Group considers that the serious problems with misreporting of catches from this stock, with many examples of vessels operating and landing herring catches distant from VIa (N) but reporting catches from that area, have been reduced in recent years from some 30,000 t in the mid 1990s to around 5,000 t in 2002. In 2003, for the first time since 1983, observer data indicated there was no misreported catch..

Catches are included in the assessment. Biases and sampling designs are not documented. Discards are not included. Slippage and high grading are not recorded.

B.2. Biological

Catch-at-age data (catch numbers-at-age, mean weights-at-age in the catch, mean length-at-age) are derived from the raised national figures received from the national laboratories. The data are obtained either by market sampling or by onboard observers, and processed as described in Section B.1 above. For information on recent sampling levels and nations providing samples, see Section 2.2. in the most recent HAWG report.

Proportions mature (maturity ogive) and mean weights-at-age in the stock derived from the acoustic survey (see next section) have been used since 1992 and 1993, respectively. Prior to these years, time-invariant values derived from ??? were used.

Biological sampling of the catches was extremely poor in recent history (particularly in 1999). This was particularly the case for the freezer trawler fishery that takes the larger component of the stock based around the shelf break. The lack of samples was due in part to the fact that national vessels tend to land in foreign ports, avoiding national sampling programs. The same fleet is thought to high grade. The long length of fishing trips makes observer programs difficult. Even when samples are taken, age determination is limited for most nations.

Sampling has improved over the last few years. The number of age readings per 1,000 t of catch increased from the low in 1999 of 52 to a high in 2001 of 93. Numbers have decreased again since then to 57 per 1,000 t in 2003. From 1999 to 2003 the sampling has been dominated by Scotland (ranging between 70 and 98% of the age readings), except in 2001, when only 43% of the age determination was on Scottish landings in VIa (N).

Natural mortality (M) varies with age (expressed in number of winter rings) according to the following:

Rings	M
1	1
2	0.3
3	0.2
4+	0.1

Those values have been held constant from 1957 to date. Those values correspond to estimates for North Sea herring based on recommendations by the Multi-species WG (Anon. 1987a) that were applied to adjacent areas (Anon. 1987b).

B.3. Surveys

B.3.1 Acoustic survey

An acoustic survey has been carried out for VIa (N) herring in the years 1987, 1991-2003. The 1997 survey was invalidated due to its unusual timing (June as oppose to July).

Biomass estimated from the acoustic survey tends to be variable. Herring are found in similar area each year, namely south of the Hebrides off Barra Head, west of the Hebrides and along the shelf edge.

The stock is highly contagious in its spatial distribution, which explains some of the high variability in the time series. Effort stratification has improved with knowledge of the distribution and this may be less of a problem in more recent years. The survey uses the same target strength as for the North Sea surveys and there is no reason to suppose why this should be any different. Species identification is generally not a great problem.

B.3.2 Larvae survey

Larvae surveys for this stock were carried out from 1973 to 1993. Larval production estimates (LPE) and a larval abundance index (LAI) were produced for the time series. These values were used in the assessment, the LPE until 2001. However, in 2002 it was decided that the LAI had no influence on the assessment and has not been used since. Documentation of this survey time-series is given in ICES CM 1990/H:40.

B.4. Commercial CPUE Not used for pelagic stocks

B.5. Other relevant data

C. Historical Stock Development

An experimental survey-data-at-age model was formulated at the 2000 HAWG. In 1999 and 1998 a Bayesian modification to ICA was used to account for the uncertainty in misreporting.

Model used: ICA

Software used: ICA (Patterson 1998b)

Model Options chosen:

- Separable constraint over last 8 years (weighting = 1.0 for each year)
- Reference age = 4
- Constant selection pattern model
- Selectivity on oldest age = 1.0
- First age for calculation of mean F = 3
- Last age for calculation of mean F = 6
- Weighting on 1-rings = 0.1; all other age classes = 1.0
- Weighting for all years = 1.0
- All indices treated as linear
- No S/R relationship fitted
- Lowest and highest feasible F = 0.02 and 0.5
- All survey weights fitted by hand i.e., 1.0 with the 1 ringers in the acoustic survey weighted to 0.1.
- Correlated errors assumed i.e., = 1.0

No shrinkage applied

Input data types and characteristics:

Түре	Name	YEAR RANGE	AGE RANGE	VARIABLE FROM YEAR TO YEAR YES/NO
Caton	Catch in tonnes	1957 - 2003	NA	Yes
Canum	Catch at age in numbers	1957 – 2003	1-9+	Yes
Weca	Weight at age in the commercial catch	1957 –1972 1973-1981 1982-1984 1985-last data year	1-9+ 1-9+ 1-9+ 1-9+	No No No Yes
West	Weight at age of the spawning stock at spawning time.	1957 – 1992 1993-last data year	1-9+ 1-9+	No Yes
Mprop	Proportion of natural mortality before spawning	1957–last data year	NA	No
Fprop	Proportion of fishing mortality before spawning	1957–last data year	NA	No
Matprop	Proportion mature at age	1957 – 1991 1992-last data year	1-9+ 1-9+	No Yes
Natmor	Natural mortality	1957-last data year	1-9+	No

Tuning data:

Түре	NAME	YEAR RANGE	AGE RANGE
Tuning fleet 1	VIa (N) Acoustic Survey	1987,	1-9+
		1991-1996	1-9+
		1998-2003	1-9+

D. Short-Term Projection

Model used: Age structured

Software used: MFDP ver 1a

Initial stock size: Taken from the last year of the assessment. 1- and 2-ring recruits taken from a geometric mean for the years 1976 to one year prior to the last year.

Maturity: Mean of the last three years of the maturity ogive used in the assessment.

F and M before spawning: Set to 0.67 for all years.

Weight at age in the stock: Mean of the last three years in the assessment.

Weight at age in the catch: Mean of the last three years in the assessment.

Exploitation pattern: Mean of the previous three years, scaled by the Fbar (3-6) to the level of the last year.

Intermediate year assumptions: status quo F constraint.

Stock recruitment model used:

None used

Procedures used for splitting projected catches: Not relevant

E. Medium-Term Projections

Model used: ICP as described in ICES 1996/ACFM:10

Software used: ICP (Patterson 1999)?

Initial stock size: Population parameters (vector of abundance at age in 2003, fishing mortality at reference age in 2003, selection at age) are drawn from a multivariate normal distribution with mean equal to the values estimated in the stock assessment model, and with covariance as estimated in the same model fit. Geometric mean recruitment for 1- and 2-ringers is used to replace the values in the assessment for the first projected year, however, the covariance values produced by ICA are retained.

Natural mortality: Mean of the last three years in the assessment.

Maturity: Mean of the last three years of the maturity ogive used in the assessment.

F and M before spawning: Set to 0.67 for all years.

Weight at age in the stock: Mean of the last three years in the assessment.

Weight at age in the catch: Mean of the last three years in the assessment.

Exploitation pattern: ???

Intermediate year assumptions: F or TAC constraint

Stock recruitment model used: Ockham option using the converged VPA 1972 to three years prior to last year in the assessment.

Uncertainty models used:

- 1. Initial stock size:
- 2. Natural mortality:
- 3. Maturity:
- 4. F and M before spawning:
- 5. Weight at age in the stock:
- 6. Weight at age in the catch:
- 7. Exploitation pattern:

Weight at age in the catch:

Exploitation pattern:

Procedures used for splitting projected catches:

G. Biological Reference Points

The report of SGPRP (ICES 2003/ACFM:15) proposed a \mathbf{B}_{lim} of 50,000 t for VIa (N) herring. This is calculated from the values in the converged part of the VPA (1976-1999) and the Working Group endorsed this value in 2003 (ICES 2003/ACFM:17).

In 2003 the Working Group estimated retrospective error in terminal SSB from 4 years and gave a mean of the absolute values of 20% and a maximum of 38%. Since there are so few data points and they are close in time to the current year the maximum value might be an underestimate of the range of values. The Working Group felt that the 90th percentile on a normal distribution that had a mean error of 20% might be a more appropriate measure; this would give a factor close to 50%.

$$\mathbf{B}_{pa} = \mathbf{B}_{lim}^* 1.50$$
 and gives $\mathbf{B}_{pa} = 75,000 \text{ t}$

The Working Group had considerable trouble developing F reference points but proposed a value based on rather limited data on errors of estimation. F_{lim} was derived directly from the equilibrium exploitation rate for an SSB for B_{lim} . F_{pa} was obtained in a similar manner to B_{pa} with a factor of 50%. Full details of the method are given in last year's Working Group report.

The Working Group did not repeat the extensive analysis carried out in 2003 (ICES 2003/ACFM:17) but suggests that, at the very least, a \mathbf{B}_{lim} of 50,000 and a \mathbf{B}_{pa} of 75,000 are suitable as Biomass limit and reference points for VIa (N). Reference points are urgently needed for the management of this stock and these values are as well founded as many others currently in use.

Suggested Precautionary Approach reference points:

B _{LIM} IS 50,000 T	B _{PA} BE SET AT 75,000 T		
$\mathbf{F}_{\mathrm{lim}}$ is 0.75	$\mathbf{F}_{\mathrm{pa}} = 0.35$		

Technical basis:

$B_{\rm Lim}; B_{\rm Loss} \ Estimated \ SSB \ for \ sustained \\ Recruitment$	$\mathbf{B}_{\mathrm{PA}} := 1.5 * \mathbf{B}_{\mathrm{LIM}}$		
${\bf F}_{lim}$ corresponding to ${\bf B}_{lim}$ from the yield-per-recruit ${\bf F}_{lim}{=}~0.75$	$\mathbf{F}_{pa} = 0.5 * \mathbf{B}_{lim}$		

H. Other Issues

H.1 Terminology

The WG uses "rings" rather than "age" or "winter rings" throughout the report to denominate the age of herring, with the intention to avoid confusion. It should be observed that, for autumn spawning stocks, there is a difference of one year between "age" and "rings". HAWG in 1992 (ICES 1992/Assess:11) stated that

"The convention of defining herring age rings instead of years was introduced in various ICES working groups around 1970. The main argument to do so was the uncertainty about the racial identity of the herring in some areas. A herring with one winter ring is classified as 2-years-old if it is an autumn spawner, and one-year-old if it is a spring spawner. Recording the age of the herring in rings instead of in years allowed scientists to postpone the decision on year of birth until a later date when they might have obtained more information on the racial identity of the herring.

The use of winter rings in ICES working groups has introduced a certain amount of confusion and errors. In specifying the age of the herring, people always have to state explicitly whether they are talking about rings or years, and whether the herring are autumn- or spring spawners. These details tend to get lost in working group reports, which can make these reports con-

fusing for outsiders, and even for herring experts themselves. As the age of all other fish species (and of herring in other parts of the world) is expressed in years, one could question the justification of treating West-European herring in a special way. Especially with the present trend towards multispecies assessment and integration of ICES working groups, there might be a case for a uniform system of age definition throughout all ICES working groups.

However, the change from rings to years would create a number of practical problems. Data files in national laboratories and at ICES would have to be adapted, which would involve extra costs and manpower. People that had not been aware of the change might be confused when comparing new data with data from old working group reports. Finally, in some areas (notably Division IIIa), the distinction between spring- and autumn spawners is still hard to make, and scientists preferred to continue using rings instead of years.

The Working Group discussed at length the various consequences of a change from rings to years. The majority of the Group felt that the advantages of such a change did not outweigh the disadvantages, and it was decided to stick to the present system for the time being."

The text table below gives an example for the correlation between age, rings and year class for the different spawning types in late 2002:

YEAR CLASS (AUTUMN SPAWNERS)	2001/2002	2000/2001	1999/2000	1998/1999
Rings	0	1	2	3
Age (autumn spawners)	1	2	3	4
Year class (spring spawners)	2002	2001	2000	1999
Rings	0	1	2	3
Age (spring spawners)	0	1	2	3

Quality Handbook ANNEX: Herring in VIaS and VIIb

Stock specific documentation of standard assessment procedures used by ICES.

Stock: Herring in VIaS and VIIb

Working Group: Herring Assessment Working Group for the

area south of 62⁰ N

Date: 19th April 2004

A. General

A.1. Stock definition

The herring to the northwest of Ireland comprise both autumn and winter spawning components. For the purpose of stock assessment and management, these areas have been separated from VIaN since 1982. Spawning in VIIb has traditionally taken place in the autumn and in VIaS, later in the autumn and in the winter.

A.2. Fishery

The TAC is taken mainly by Ireland, which has over 90% of the quota. In recent years, only Ireland has exploited herring in this area. In 2000 the Irish North West Pelagic Management Committee was established to deal with the management of this stock.

Landings have decreased markedly from about 44,000 t in 1990 to around 13,000 t in 2003.

A.3. Ecosystem aspects

B. Data

B.1. Commercial catch

The commercial catches are provided by national laboratories belonging to the nations that have quota for this stock. In recent years, only Ireland has caught herring in this area, so catch-at-age, mean weights and stock weights are derived entirely from Irish sampling. Sampling is performed as part of commitments under the EU Council Regulation 1639/2001.

Commercial catch at age data are submitted in Exchange sheet v 1.6.4. These data are usually processed using SALLOCL. This program (Patterson, 1998) gives outputs on sampling status and available biological parameters and documents actions taken to raise unsampled metiers using other data sets. The species co-ordinator allocates samples of catch numbers, mean length and mean weight-at-age to unsampled catches using appropriate samples by gear (fleet) area quarter and if an exact match is not available then a neighbouring area if the fishery extends to this area in the same quarter.

B.2. Biological

Mean weights at age in the catch in the 4th and 1st quarter are used as stock weights.

B.3. Surveys

Not used in assessment

B.4. Commercial CPUE

Not used in assessment

B.5. Other relevant data

C. Historical Stock Development

Model used:

A separable VPA is used to track the historic development of this stock.

Software used:

Lowestoft VPA Package (Darby and Flatman, 1994). No final assessment has been accepted by the working group. However several scenarios are run, screening over a range of terminal F's and each is presented in the report.

Input data types and characteristics:

Stock: Irish Sea herring

Working Group Herring Assessment Working Group

(HAWG)

Date: 17 March 2004

A. General

A.1. Stock definition

Herring spawning grounds in the Irish Sea are found in coastal waters to the west and north of the Isle of Man and on the Irish Coast at around 54°N (ICES 1994, Dickey-Collas *et al.* 2001). Spawning takes place from September to November in both areas, occurring slightly later on average on the Irish Coast than off the Isle of Man. ICES Herring Assessment Working Groups from 19XX to 1983 used v ertebral counts to separate catches into Manx and Mourne stocks associated with these spawning grounds. However, taking account of inaccuracies in this method and the results of biochemical analyses, the 1984 WG combined the data from the two components to provide a "more meaningful and accurate estimate of the total stock biomass in the N.Irish Sea." All subsequent assessments have treated the VIIa(N) data as coming from a single stock. During the 1970s, catches from the Manx component were about three times larger than those from the Mourne component. By the early 1980s, following the collapse of the stock, the catches were of similar magnitude. The fishery off the Mourne coast declined substantially in the 1990s then ceased, whilst acoustic and larva surveys in this period indicate that the spawning population in this area has been very small compared to the biomass off the Isle of Man.

The occurrence in the Irish Sea of juvenile herring from a winter-spring spawning stock has been recognized since the 1960s based on vertebral counts (ICES 1994). More recently, Brophy and Danilowicz (2002) used otolith microstructure to show that nursery grounds in the western Irish Sea were generally dominated by winter-spawned fish. Samples from the eastern Irish Sea were mainly autumn-spawned fish. Recaptures from 10,000 herring tagged off the SW of the Isle of Man in July 1991 occurred both on the Manx spawning grounds and along the Irish Coast with increasing proportions from the Celtic Sea in subsequent years (Molloy *et al.*, 1993). The pattern of recaptures indicated a movement towards spawning grounds in the Celtic Sea as the fish matured.

A proportion of the Irish Sea herring stocks may occur to the north of the Irish Sea outside of the spawning period. This was indicated by the recapture on the Manx spawning grounds of 3-6 ring herring tagged during summer in the Firth of Clyde (Morrison and Bruce 1981). Aggregations of post-spawning adult herring were detected along the west coast of England during an acoustic survey in December 1996 (Department of Agriculture and Rural Development for Northern Ireland, unpublished data), showing that a component of the stock may remain within the Irish Sea.

A recent EU-funded programme WESTHER aims to elucidate stock structures of herring throughout the western seaboard of the British Isles using a combination of morphometric measurements, otolith structure, genetics and parasite loads. The results of this should provide the best-available information on mixing of stocks within and beyond the Irish Sea.

A.2. Fishery

There have been three types of fishery on herring in the Irish Sea in the last 40 years:

- i. Isle of Man- aimed at adult fish that spawn around the Isle of Man.
- ii. Mourne- aimed at adult fish that spawn off the Northern Irish eastern coast.
- Mornington- a mixed industrial fishery that caught juveniles in the western Irish Sea.

The Mornington fishery started in 1969 and at its peak it caught 10,000 tonnes per year. It took place throughout the year. The fishery was closed due to management concerns in 1978 (ICES, 1994). In the 1970s the catch of fish from the Mourne fishery made up over a third of the total Irish Sea catch. The fishery was carried out by UK and Republic of Ireland vessels using trawls, seines and drift nets in the autumn. However the fishery declined and ceased in the early 1990s (ICES, 1994). The biomass of Mourne herring, determined from larval production estimates is now 2-4% of the total Irish Sea stock (Dickey-Collas *et al.*, 2001).

The main herring fishery in the Irish Sea has been on the fish that spawn in the vicinity of the Isle of Man. The fish are caught as they enter the North Channel, down the Scottish coast, and around the Isle of Man. Traditionally this fishery supplied the Manx Kipper Industry, which requires fish in June and July. However the fish appeared to spawn slightly later in the year in the 1990s and this lead to problems of supply for the Manx Kipper Industry. In 1998 the Kipper companies decided to buy in fish from other areas. Generally the fishery has occurred from June to November, but is highly dependent on the migratory behaviour of the herring.

The fishery has been prosecuted mainly by UK and Irish vessels. TACs were first introduced in 1972, and vessels from France, Netherlands and the USSR also reported catches from the Irish Sea during the 1970s before the closure of the fisheries from 1978 to 1981. By the 1990s only the fishery on the Manx fish remained, and by the late 1990s this was dominated by Northern Irish boats. The number of Northern Irish vessels landing herring declined from 24 in 1995-96 to 6-10 in 1997-99 and to 4 in 2000. Only two vessels operated in 2002 and 2003. However, total landings have remained relatively stable since the 1980s whilst the mean amount of fish landed per fishing trip has increased, reflecting the increase in average vessel size

A.3. Ecosystem aspects

The main fish predators on herring in the Irish Sea include whiting (*Merlangius merlangus*), hake (*Merluccius merluccius*) and spurdogfish (*Squalus acanthias*). The size composition of herring in the stomach contents indicates that predation by whiting is mainly on 0-ring and 1-ring herring whilst adult hake and spurdogfish also eat older herring (Armstrong, 1979; Newton, 2000; Patterson, 1983). Sampling since the 1980s has shown cod (*Gadus morhua*), taken by both pelagic and demersal trawls in the Irish Sea, to be minor predators on herring. Small clupeids are an important source of food for piscivorous seabirds including gannets, guillemots and razorbills (ref...) which nest at several locations in and around the Irish Sea. Marine mammal predators include grey and harbour seals (ref.) and possibly pilot whales, which occur seasonally in areas where herring aggregate.

Whilst small juvenile herring occur throughout the coastal waters of the western and eastern Irish Sea, their distribution overlaps extensively with sprats (*Sprattus sprattus*). The biomass of small herring has typically been less than 5% of the combined biomass of small clupeids estimated by acoustics (ICES HAWG reports).

B. Data

B.1. Commercial catch

National landings estimates

The current ICES assessment of Irish Sea herring extends back to 1961, and is based on landings only. ICES WG reports (ICES 1981, 1986 and 1991) highlight the occurrence of discarding and slippage of catches, which can occur in areas where adult and juvenile herring cooccur. Discarding has been practised on an increasing scale since 1980 (ICES 1986). This increase is primarily related to the onset of slippage of catches that coincided with the cessation of the industrial fishery in early 1979 (ICES 1980). As a result of sorting practices, slippage has led to marked changes in the age composition of the catch since 1979 and considerable change in the mean weights at age in the catch of the three youngest age groups (ICES 1981). Estimates of discarding were sporadically performed in the 1980s (ICES 1981, 1982, 1985 and 1986), but there are no estimates of discarding or slippage of herring in the Irish Sea fisheries since 1986. Highly variable annual discard rates are evident from the 1980s surveys. For example, discards estimates of juvenile herring (0-group) for the Mourne stock taken in the 1981 Nephrops fishery was estimated at 1.9x10⁶ of vessels landing in Northern Ireland, which amounts to approximately 20% of the Mourne fishery (ICES 1982). In 1982, at least 50% of 1-group herring caught were discarded at sea by vessels participating in the Isle of Man fishery (ICES 1983). A more comprehensive survey programme to determine the rate of discarding in 1985 revealed discard estimates of 82% by numbers of 1-ring fish, 30% of 2-ring and 6% of 3-ring fish, with the dominant age group in the landed catch being 3 ring (ICES 1986). A similar survey in 1986, however, found the discarding of young fish fell to a very low level (ICES 1987). The 1991 WG discussed the discard problem in herring fisheries in general and suggested possible measures to reduce discarding. No quantitative estimates were given, but reports of fishermen suggesting discards of up to 50% of catch as a result of sorting practices by using sorting machines (ICES 1991). The variation in discard rates since 1980, as a result of changes in discard practices, can probably be attributed to several changes in the management of the fishery. These include the availability of different fishing areas, the change to fortnightly catch quotas per boat (ICES 1987) and level of TAC, where lower discard rates are observed with a higher TAC (ICES 1989). The level of slippage is also related to the fishing season, since slippage is often at a high level in the early months (ICES 1987). Due to the variable nature of discard estimates and the lack of a continuous data series, it has not been included in the annual catch at age estimates (with the exception of the 1983 assessment when the catch in numbers of 1-ringers was doubled based on a 50% discard estimate of this age group).

Landings data for herring in Division VIIa(N) are generally collated from all participating countries providing official statistics to ICES, namely UK (England & Wales, Northern Ireland, Scotland and the Isle of Man), Ireland, France, the Netherlands and what was formally the USSR. The data for the period 1971 to present are reported in the various Herring Assessment Working Group Reports and are reproduced in Table 1. The official Statistics for Irish landings from VIIa have been processed to remove data from the Dunmore East fishery in area VIIa(S), and represent landings from VIIa(N) only.

Over the past three decades, the WG highlighted the under- or misreporting of catches as the major problem with regards to the accuracy of the landing data. Related to this are the problems of illegal landings during closed periods and paper landings. Area misreporting was also recognised (ICES 1999), although a less prominent problem that is mostly corrected for.

The 1980 WG first identified the problem of misreporting of landings based on the results of a 3-year sampling programme, which was initiated after 1975 when herring were being landed in metric units at ports bordering the Irish Sea (1 unit = 100 kg nominal weight). The study

showed the weight of a unit to be very variable, but was usually well in excess of 100 kg. An initial attempt to allow for misreporting using adjusted catches made very little difference to any of the values of fishing mortality (ICES 1980). Subsequently, despite serious concerns about considerable under-reporting being raised (ICES 1990, 1994, 2000 and 2001), the WG made no attempts to examination the extent of the problem. This uncertainty signifies no estimates of under-reporting and consequently no allowance for under-reporting of landings has been made. Considerable doubt was raised as to the accuracy of landing data over the period 1981-87 (ICES 1994). However, after apparent re-examination all WG landing statistics are assumed to be accurate up to 1997 (ICES 2000), but with no reliable estimates of landings from 1998-2000 (ICES 2001). The WG acknowledged that poor quality landing data bring the catch in numbers at age data into question and hence the accuracy of any assessment using data from such periods (ICES 1994).

In 2002 the ICES assessment was extended back to include data for 1961-1970 with the intention of showing the stock development prior to the large expansion in fishing effort and stock size in the early 1970s. This has now been extended further back to 1955. Landings data for this period were extracted from the UK fisheries data bases (England & Wales, Scotland and Northern Ireland: Table 1, columns8-10) and publications by Bowers and Brand (1973) for Isle of Man landings (column 11). Landings data for Ireland and France were not available.

To estimate the VIIa(N) herring landings for Ireland and France during 1955-1970, the NE Atlantic herring catches for each country were obtained from the FAO database (column 16). Using the ICES landings data for each country (column 17) the mean proportion of the VIIa(N) catch to the NE Atlantic catch during 1971 to 1981 was estimated (column 18). This was applied to the NE Atlantic catches from each country, for the period 1955 to 1970, to give an estimated landing for both France and Ireland (column 19). These landings were added to the known catches from the CEFAS database to give the total landings. The landings data (tonnes) used in the assessment are given in Table 1, column 14. It is anticipated that landings data for VIIa(N) for years prior to 1971 can be extracted from the Irish databases. However, the French landings will remain as estimates.

[Need discussion on magnitude of errors in the old data]

[Need discussion on errors due to misreporting]

Catch at age data

Age classes in the ICES Canum file refer to numbers of winter rings in otoliths. As the Irish Sea stock comprises autumn spawners, i-ring fish taken in year y will comprise fish in their ith year of life if caught prior to the spawning season and (i+1)th year if caught after the spawning period. An i-ring fish will belong to year-class y-2. As spawning stock is estimated at spawning time (autumn), spawning stock and recruitment relationships require estimates of recruitment of i-ring fish in year y and estimates of SSB in year i-2. The current assessment estimates recruitment as numbers of 1-ring fish.

The most recent description of sampling and raising methods for estimating catch at age of herring stocks is in ICES (1996). This includes sampling by UK(E&W) and Ireland, but not UK(NI) and Isle of Man

UK(NI): A random sample of 10-20kg of herring is taken from each landing into the main landing port (Ardglass) by the NI Department of Agriculture and Rural Development. Samples are also collected from any catches landed into Londonderry. Prior to the 1990s, the samples were mostly processed fresh. During the 1990s, there was an increasing tendency for samples to be frozen for a period of weeks before processing. No corrections have been applied to weight measurements to allow for changes due to freezing and defrosting. The length frequency (total length) of each

sample is recorded to the nearest 0.5cm below. A sample of herring is then taken for biological analysis as follows: one fish per 0.5 cm length class, followed by a random sample to make the sample up to 50 fish.

Otoliths are removed from each fish, mounted in resin on a black slide and read by reflected light. Ages are assigned according to number of winter rings.

Length frequencies (LFDs) for VIIa(N) catches are aggregated by quarter. The weight of the aggregate LFD is calculated using a length-weight relationship derived from the biological samples. The LFD is then raised to the total quarterly landings of herring by the NI fleets. A quarterly age-length key, derived from commercial catch samples only, is applied to the raised LFD to give numbers at age and mean weight at age.

IOM: IOM sampling covers the period 1923 – 1997. Samples are collected from any landings into Peel, by staff of the Port Erin Marine Laboratory (Liverpool University). The sampling and raising procedures are the same as described for UK(NI) with the following exceptions: i) the weight of the aggregate quarterly LFD is obtained from the original sample weights rather than using a length-weight relationship, and ii) the biological samples are random rather than stratified by length. The 1993 ICES herring assessment WGs noted a potential under-estimation by one ring, of herring sampled in the IOM. This was caused by a change in materials used for mounting otoliths and appears to have been a problem for ageing older herring in 1990-92. This was since rectified. However, the bias for the 1990-92 period has not yet been quantified and will be examined in the near future.

Ireland: Irish sampling of VIIa(N) herring covers the period 19xx – 2001. Some samples are from landings into NI but transported to factories in southern Ireland. Irish sampling schemes for herring in Div. VIa(S), VIIb, Celtic Sea and VIIj are described in ICES (1996). Methods for sampling catches in VIIa(N) are similar. The procedure is the same as described above for UK(NI) except that the biological samples are random rather than length stratified. ICES (1996) notes that a length-stratified scheme should be adopted to ensure proper coverage at the extremes of the LFDs.

Quality control of herring ageing has fallen under the remit of EU funded programmes EFAN and TACADAR, to which the laboratories sampling VIIa(N) herring contribute. An otolith exchange exercise was initiated in 2002 and is currently being completed.

B.2. Biological

Natural mortality (M) varies with age (expressed in number of winter rings) according to the following:

Rings	M
1	1
2	0.3
3	0.2
4+	0.1

Those values have been held constant from 1972 to date. Those values correspond to estimates for North Sea herring based on recommendations by the Multi-species WG (Anon. 1987a). which were applied to adjacent areas (Anon. 1987b).

Maturity at age. Combined, year-specific maturity ogives were used in the 2003 Assessment (ICES 2003). The way those values were derived is documented on Dickey-Collas *et al.*

(2003). Prior to 2003 annually invariant estimates of the proportion of fish mature by age were used. Those were based on estimates from the 1970s (ICES, 1994). The use of the variable maturity ogive in 2003 did not change greatly the perception of the stock state (Dickey-Collas *et al.*, *op cit*).

SSB in September is estimated in the assessment. The survey larvae estimate is used as a relative index of SSB. The proportions of M and F before spawning are held constant over time in the assessment.

Stock weights at age have been derived from the age samples of the 3rd quarter landings since 1984 (R. Nash *pers comm.*). The stock mean weights for 1975-83 are time invariant and were re-examined in 1985 (Anon. 1985). They result from combining Manx and Mourne data sets. The weight at age of those stocks were considered relatively stable over time.

B.3. Surveys

The following surveys provide data for the VIIa(N) assessment:

SURVEY ACRONYM	Түре	ABUNDANCE DATA	AREA AND MONTH	Period
AC(VIIaN)	Acoustic survey	Numbers at age (1-ring and older); SSB	VIIa(N) from 53 ⁰ 20'N – 55°N; September	1994 – present
NINEL	Larva survey	Production of larvae at 6mm TL	VIIa(N) from 53° 50'N – 54° 50'N; November	1993 – present
DBL	Larva survey	Production of larvae at 6mm TL	East coast of Isle of Man; October	1989 – 1999 (1996 missing)
GFS-oct	Groundfish survey	Mean nos. caught per 3 n.miles (1&2 ringers), by region	VIIa(N) from 53 ^o 20'N – 54 ^o 50'N (stratified); October	1993 - present
GFS-mar	Groundfish survey	Mean nos. caught per 3 n.miles (1&2 ringers), by region	VIIa(N) from 53 ^o 20'N – 54 ^o 50'N (stratified); March	1993 - present

Data from a number of earlier surveys have been documented in the ICES WG reports. These include:

NW Irish Sea young herring surveys (Irish otter trawl survey using commercial trawler; 1980 – 1988)

Douglas Bank (East Isle of Man) larva surveys (ring net surveys; 1974 – 1988) (Port Erin Marine Lab)

Douglas Bank spawning aggregation acoustic surveys (1989, 1990, 1994, 1995) (Port Erin Marine Lab)

Western Irish Sea acoustic survey (July 1991, 1992) (UK(NI))

Eastern Irish Sea acoustic survey (December 1996)

Surveys used in recent assessments are described below.

AC(VIIaN) acoustic survey

This survey uses a stratified design with systematic transects, during the first two weeks of September. Vessel used is the R.V. *Lough Foyle* (UK(NI)). Starting positions are randomized each year (see recent HAWG reports for transect design and survey results). The survey is most intense around the Isle of Man (2 to 4 n.mile transect spacing) where highest densities of adult herring are expected based on previous surveys and fishery data. Transect spacing of 6 to 10 n.miles are used elsewhere. A sphere-calibrated EK-500 38kHz sounder is employed, and

data are archived and analysed using Echoview (SonarData, Tasmania). Targets are identified by midwater trawling. Acoustic records are manually partitioned to species by scrutinising the echograms and using trawl compositions where appropriate. ICES-recommended target strengths are used for herring, sprat, mackerel, horse mackerel and gadoids. The survey design and implementation follows, where possible, the guidelines for ICES herring acoustic surveys in the North Sea and West of Scotland. The survey data are analysed in 15-minute elementary distance sampling units (approx. 2.5 n.miles). An estimate of density by age class, and spawning stock biomass, is obtained for each EDSU and a distance-weighted average calculated for each stratum. These are raised by stratum area to give population numbers and SSB by stratum.

NINEL larva survey

The DARD herring larva survey has been carried out in November each year since 1993 . Sampling is carried out on a systematic grid of stations covering the spawning grounds and surrounding regions in the NE and NW Irish Sea (Figure 1). Larvae are sampled using a Gulf-VII high-speed plankton sampler with 280 μm net. Double-oblique tows are made to within 2m of the seabed at each station. Internal and external flow rates, and temperature and salinity profiles, were recorded during each tow. Lengths of all herring larva captured are recorded.

Mean catch-rates (nos.m⁻²) are calculated over stations to give separate indices of abundance for the NE and NW Irish Sea. Larval production rates (standardised to a larva of 6mm), and birth-date distributions, are computed based on the mean density of larvae by length class. A growth rate of 0.35mm day⁻¹ and instantaneous mortality of 0.14 day⁻¹ are assumed based on estimates made in 1993 - 1997. More recent studies have indicated a mortality rate of 0.09, and this value is also applied to examine the effect on trends in estimates of larval production

DBL larva survey

Herring larvae were sampled on the east side of the Isle of Man in September or October each year. Double oblique tows with a 60 cm Gulf VII/PRO-NET high-speed plankton sampler with a 40cm aperture nose cone were undertaken on a 5 Nm square grid. The tow profile was followed with a FURUNO net sonde attached to the top of the equipment. The volume of water filtered was calculated from the nose cone mouth flow meter. The samples were preserved in 4% seawater buffered formalin and stored in 70% alcohol.

All herring larvae were sorted from the samples. The numbers of larvae per m³ were calculated from the volume of water filtered and the number of larvae per tow. Up to 100 larvae from each tow were measured with an ocular graticule in a stereo microscope. Each sample was assigned to a sampling square and the total number of larvae per 0.5mm size class calculated from the average depth of the square and the surface area.

The total production and time of larvae hatch was calculated using an instantaneous mortality coefficient (k) of 0.14 and a growth rate of 0.35 mm d⁻¹ in the formula:

$$N_t = N_o e^{-(kt)}$$

Production was calculated as the sum of all size classes/hatching dates. Spawning dates were taken as 10 days prior to the hatching date (Bowers 1952).

GFS-oct and -mar groundfish surveys

The DARD groundfish survey of ICES Division VIIaN are carried out in March and October 2003 at standard stations between 53° 20'N and 54° 45'N (Figure 2). Data from additional stations fished in the St George's Channel since October 2001 have not been used in calculat-

ing herring indices of abundance. As in previous surveys, the area was divided into strata according to depth contour and sediment type, with fixed station positions (note that the strata in Fig. 2 differ from those in the September acoustic survey shown in Fig. 1). The sampling gear was a Rockhopper otter trawl fitted with non-rotating rubber discs of approximately 15 cm diameter on the footrope. The trawl fishes with an average headline height of 3.0 m and door spread of 30 - 40 m depending on depth and tide. A 20mm stretched-mesh codend liner was fitted. During March, trawling was carried out at an average speed of 3 knots across the ground, over a standard distance of 3 nautical miles at standard stations and 1 nautical mile in the St. George's Channel. Since 2002, all survey stations in the October survey have been of 1-mile distance. Comparative trawling exercises during the October surveys and during an independent exercise in February 2003 indicate roughly similar catch-rates per mile between 1-mile and 3-mile tows. It is planned to continue with some comparative trawling experiments during future surveys to improve the statistical power of significance tests between the 1-mile and 3-mile tows.

As the surveys are targeted at gadoids, ages were not recorded for herring. The length frequencies in each survey were sliced into length ranges corresponding to 0-ring and 1-ring herring according to the appearance of modes in the overall weighted mean length frequency for each survey. Some imprecision will have resulted because of the overlap in length-at-age distributions of 1-ring and 2-ring herring. The error is considered to be comparatively small for most of the surveys where clear modes are apparent. There was no clear division between 1-ring and 2-ring herring in the March 2003 groundfish survey, and the estimate for 1-ringers may include a significant component of small 2-ringers. The arithmetic mean catch-rate and approximate variance of the mean was computed for each age-class in each survey stratum, and averaged over strata using the areas of the strata as weighting factors.

B.4. Commercial CPUE

Commercial CPUE's are not used for this stock.

B.5. Other relevant data

C. Historical Stock Development

Model used: ICA

Software used: ICA (Patterson 1998)

Model Options chosen:

- Separable constraint over last 6 years (weighting = 1.0 for each year)
- Reference age = 4
- Constant selection pattern model
- Selectivity on oldest age = 1.0
- First age for calculation of mean F = 2
- Last age for calculation of mean F = 6
- Weighting on 1-rings = 0.1; all other age classes = 1.0
- Weighting for all years = 1.0
- · All indices treated as linear
- No S/R relationship fitted
- Lowest and highest feasible F = 0.05 and 2.0
- All survey weights fitted by hand i.e., 1.0 with the 1 ringers in the acoustic survey weighted to 0.1.
- Correlated errors assumed i.e., = 1.0
- No shrinkage applied

Input data types and characteristics:

ТүрЕ	NAME	YEAR RANGE	AGE RANGE	VARIABLE FROM YEAR TO YEAR YES/NO
Caton	Catch in tonnes	1961-last data year	NA	Yes
Canum	Catch at age in numbers	1961-last data year	1-8+	Yes
Weca	Weight at age in the	1961-1971	1-8+	Yes
	commercial catch	1972-1983	1-8+	No
		1984-last data year	1-8+	Yes

D. Short-Term Projection

NOT USED IN 2004

Model used: Age structured

Software used: MFDP ver 1a

Initial stock size: Taken from the last year of the assessment. 1-ring recruits taken from a geometric mean for the years 1983 to two years prior to the current year. Where 1-ringers are absurdly estimated in the assessment 2-ringers are estimated as a geometric mean of the previous 10 year period.

Maturity: Mean of the previous three years of the maturity ogive used in the assessment.

 \boldsymbol{F} and \boldsymbol{M} before spawning: Set to 0.9 and 0.75 respectively for all years.

Weight at age in the stock: Mean of the previous three years in the assessment.

Weight at age in the catch: Mean of the previous three years in the assessment.

Exploitation pattern: Mean of the previous three years, scaled by the Fbar (2-6) to the level of the last year.

Intermediate year assumptions: TAC constraint.

Stock recruitment model used: None used

Procedures used for splitting projected catches: Not relevant

E. Medium-Term Projections

F. Long-Term Projections

Not done

G. Biological Reference Points

Until there is confidence in the assessment the Working Group decided not to revisit the estimation of \mathbf{B}_{pa} (9,500 t) and \mathbf{B}_{lim} (6,000 t). There were no new points to add to the discussions and deliberations presented in 2000 (ICES 2000/ACFM:10).

COVERAGE: Sum of the landings (by Q and Nation(UK disaggregated))/total landings. From 1993 (possibly from 1990) to date landings and sampling levels are presented by quarter so coverage is related to this level of detail:

VERY GOOD (v.g) : all landings which individually are >10% of the total were sampled, all Q for which there were landings were sampled

GOOD (g) : landings that constitute the majority of the catch (adding to approx 70% or more of total) were sampled

POOR (p) : some of the large landings not sampled

- (1): unsampled quarters
- (2): large landings with few samples or unsampled. High level of sampling corresponds to 1 sample per 100t landed (WG rep 1997)
- (3): Comment from WG rep. From 1990 going back, Report landings and sampling levels are shown aggregated for the whole year. UK landings lumped in one figure.
- (4): no information in the WGrep of level of sampling prior to 1988. Sampling levels believed to be good. Actual figures to be provided by R. Nash, M Armstrong and CEFAS after going back to their labs.
- (5): NO samples for NI landings in 4th Q, there is a suspicion that the figures correspond to 'paper landings'.

 1 Samples applied to NI landings: 2 Large unsampled landings.

Table ??: Data and method used to estimate landings from Division VIIa(N) herring.

- Key to strata: 1. Irish Coast (N), <100m, Mixed sediments
 - 2. Irish Coast, < 50m, sand and finer sediments
 - 3. Irish Coast, 50 100m, Muddy sediments
 - 4. W and SW Isle of Man, 50 100m, mud and muddy sand
 - 5. N Isle of Man, <50m, gravel sediments
 - 6. Eastern Irish Sea, <50m, sand and finer sediments
 - 7. S. Isle of Man, <100m, gravel sediments
 - 8. Deep western channel and North Channel >100m
 - 9. St George's Channel west; sandy/mixed sediments; <100m
 - 10. St George's Channel east; sandy/mixed sediments; <100m

Figure 2. Standard station positions for DARD groundfish survey of the Irish Sea in March and October. Boundaries of survey strata are shown. Indices for the "Western Irish Sea" use data from strata 2 - 4. Indices for the "Eastern Irish Sea" use data from stratum 6 only (few juvenile herring are found in stratum 7). (Note different stratification to Fig. 1.). New stations fished in the St Georges Channel (strata 9 and 10) since October 2001 are not included in the survey indices. Stratum 5 (1 station only in recent years) is also excluded from the index. There are no stations in stratum 8 due to difficult trawling conditions for the gear used in the survey. Station 121 in stratum 7 has been fished only once and is excluded from the index.

Working Group Herring Assessment Working Group

(HAWG)

Date: 4TH March 2004

A. General

A.1. Stock definition

Sprat in ICES area IV.

A.2. Fishery

The Danish small meshed fishery is responsible for the majority of the landings. A study undertaken in 2000 showed that the species composition in the Danish sprat fishery has changed towards a fishery with low by-catches of other species (ICES CM 2001/ACFM:12). The Norwegian sprat fishery is carried out by purse- seiners. A closure of the Norwegian fishery was introduced for the second and third quarter in 1999 and this management regime is still in force. On top of this management regime, a maximum quota (900 t) per vessel is set for the Norwegian vessels; and they are not allowed to fish in Norwegian waters until the Norwegian quota in EU waters has been taken. The majority of the catches in both fisheries is taken in the 4th quarter, though some fishery takes place during January and February.

There was a considerable increase in landings from about 10,000 t in 1986 to a peak of 320,000 t in 1995. From 2000 the landings have been relatively stable around 150,000 to 170,000 t.

A.3. Ecosystem aspects

B. Data

B.1. Commercial catch

The commercial catch is provided by the national laboratories belonging to nations exploiting the sprat in the North Sea. The sampling intensity for biological samples, i.e., age and weight-at-age is mainly performed following the EU regulation 1639/2001 as the country landing most of the catches follows this regulation. This provision requires 1 sample per 2000 tonnes landed. This sampling level is lower than the guidelines (1 sample per 1000 tonnes) previously used by the HAWG, but as the fishery is carried out in a limited area, the recommended sampling level can be regarded as adequate.

The majority of commercial catch and sampling data are submitted in the Exchange sheet v. 1.6.4 and further processed with the SALLOCL-application (Patterson 1998). This program gives outputs on sampling status and available biological parameters and documents actions taken to raise unsampled metiers using other data sets. The species co-ordinator allocates

samples of catch numbers, mean length and mean weight-at-age to unsampled catches using appropriate samples by gear (fleet) area quarter and if an exact match is not available then a neighbouring area if the fishery extends to this area in the same quarter.

B.2. Biological

Mean weights at age in the catch in the 1st quarter are used as stock weights.

Natural mortality. Results from the multi-species VPA (.Report from the ICES Workshop on Multi-species VPA in the North Sea, Charlottenlund, Denmark 8th-12th April 2002: ICES CM 2002/D:04) are used as a basis to fix the value of M in the CSA model. The estimated values presented in table XX correspond to predation mortality. To estimate total natural mortality a value of 0.2 to account for other sources of natural mortality should be added to the predation mortality.

B.3. Surveys

The acoustic surveys for the North Sea Herring in June-July have estimated sprat abundance since 1996. In the initial years low sprat biomass was estimated but those were not thought to be representative mainly due to inappropriate coverage of the south-eastern area (ICES CM 2000/D:07), the area expected to have the highest abundance of sprat in the North Sea. In 2000 the survey was extended by 30 n.mi to the south and covered for the first time the south-eastern area considered to have the highest abundance of sprat in the North Sea. By doing so, the estimate of sprat increased significantly. The distribution pattern in 2002 demonstrates, however, that the southern distribution border was still not reached by the survey. Further, the inshore areas were sprat is expected to be abundant are not covered so, the survey can only be seen as indicative of trends in biomass.

The IBTS (February) sprat indices (no per hour) in IVb (sprat standard area) are used as an index of abundance. The historical data were revised in 1995 (ICES 1995/Assess:13) and 1999 (ICES 1999/ACFM:12). The IBTS Working Group redefined the sprat index to be calculated as an area weighted mean over means by rectangles for the entire North Sea sprat stock. Based on this, the IBTS WG asked ICES Secretariat to carry out new calculations in 2001 (ICES 2000/D:07), which are the ones used at present. The fishing method (gear) in the IBTS-survey was standardised in 1983 and the data series from 1984, are comparable. The old IBTS-indices are available in ICES 2001/ACFM:12.

B.4. Commercial CPUE

Not used for this stock.

B.5. Other relevant data

C. Historical Stock Development

Model used:

Sprat is a relatively short-lived species, the stock and the catches, consisting mostly of 1 and 2 year-olds. In addition, there are difficulties in age reading resulting in unreliable estimates of numbers at age both from the surveys and the commercial catch. Given those limitations a data exploration using Catch-Survey Analysis (CSA), an assessment method designed for cases where full age-structured data are missing, was undertaken by the WG in 2003. The method is based on the "modified DeLury" two-stage model (Conser 1995) and on an implementation tested on simulated data presented to the Methods Working Group in 2003 (Mesnil 2003). The model assumes that the population consists of two stages: the recruits (preferably a single year-class) and the fully recruited ages.

590 ICES Template Header

Software used:

CSA executable version made available by B. Mesnil (IFREMER).

Model Options chosen:

Input data types and characteristics:

Model input data consisting of the time-series of catch numbers for each stage, mean weight for each stage in the stock at the start of the year and the 1st quarter IBTS index of abundance for the 1 year-old sprat (age = number of winter rings) and older than 2 years-old. Given low sampling levels in years previous to 1995, constant weight at age based on commercial data from the 1st quarter was assumed for the whole period. Reservations regarding the ability of the IBTS 1-year-old index to fully reflect strong and weak cohorts for sprat were expressed in previous WG reports (see ICES 1998 ACFM:14). Those were linked to difficulties in age reading and/or a possible prolonged spawning and recruitment season. Another problem identified in some surveys was related to large catches in small areas which could have been very influential on the results. Examination of the biomass and the 1 year-old index trajectories by the WG in 2003, suggested that the observed fluctuations in overall biomass are related to a large extent to observed fluctuations in the 1 year-old index. This is to be expected in a population where the recruits account for a large proportion of the stock. A unique value for the instantaneous rate of natural mortality (M = 0.4) and a parameter corresponding to the ratio of the survey catchability of the recruits to the fully recruited ages (s = 1) were fixed externally.

D. Short-Term Projection

Model used:

The SHOT- approach (Shepherd, 1991) was used in the past by the WG to estimate the landings in the assessment year. The 2003 WG considered that approach inappropriate for a short-lived stock like sprat therefore the projection was based on the results from CSA.

A catch prediction for the assessment year is based on a linear regression of annual catch versus IBTS estimated biomass for the period starting in 1987.

Software used:

Initial stock size:

Maturity:

F and M before spawning:

Weight at age in the stock:

Weight at age in the catch:

Exploitation pattern:

Intermediate year assumptions:

Stock recruitment model used:

Procedures used for splitting projected catches:

E. Medium-Term Projections

Not performed

F. Long-Term Projections

Not performed

G. Biological Reference Points

Not set.

H. Other Issues

Only in-year catch forecasts are available. The stock consists of only a few year classes, with a predominance of 1-year-old fish in the catch.

Date: 16TH March 2004

A. General

A.1. Stock definition

Sprat in ICES area VIId, VIIe,f.

A.2. Fishery

Vessels from UK (England and Wales) are responsible for the vast majority of the catches. The majority of the catches are taken in the 3rd and 4th quarter.

The landings in this area are very small and have never been above 6,000 t since 1985. Since 2000 the landings have been stable around 1,500 t.

A.3. Ecosystem aspects

B. Data

B.1. Commercial catch

The commercial catch is provided by the national laboratories belonging to nations exploiting the sprat in the Division VIId and VIIe,f. The sampling intensity for biological samples, i.e., age and weight-at-age has not been performed since 1999, but as the fishery is so small, this is not considered to be a problem.

B.2. Biological

B.3. Surveys

There are no surveys targeting sprat in this area.

ANNEX: Sprat IIIa

Appendix 10 Stock Annex

Quality Handbook

Stock specific documentation of standard assessment procedures used by ICES.

Stock: Sprat in Division IIIa

Working Group: Herring Assessment Working Group

(HAWG)

Date: 16th March 2004

A. General

A.1. Stock definition

Sprat in ICES area IIIa

A.2. Fishery

Fleets from Denmark, Norway and Sweden carry out the sprat fishery in Division IIIa. The Danish sprat fishery consists of trawlers using a 16 mm-mesh size codend and all landings are used for fishmeal and oil production. Some of the sprat landings from Denmark and Sweden are by-catches in the herring fishery using 32 mm mesh-size cod ends. The Swedish fishery is directed at sprat with by-catches of herring but also includes a fishery carried out with small purse seiners at the West Coast of Sweden for human consumption. The Norwegian sprat fishery in Division IIIa is an inshore purse seine fishery for human consumption.

The majority of the landings are made by the Danish fleet. In 1997 a mixed-clupeoid fishery management regime was changed to a new agreement between the EU and Norway that resulted in a TAC for sprat as well as a by-catch ceiling for herring. Catches are taken in all quarters, though with the bulk of catches in the first and fourth quarter. Denmark has a total ban on the sprat fishery in Division IIIa from May to September.

There was a considerable increase in landings from about 10,000 t in 1993 to a peak of 96,000 t in 1994. From 1996 the landings has been stabilising around 20,000 t.

A.3. Ecosystem aspects

B. Data

B.1. Commercial catch

The commercial catch is provided by the national laboratories belonging to nations exploiting the sprat in Division IIIa. The sampling intensity for biological samples, i.e., age and weight-at-age is mainly performed following the EU regulation 1639/2001 as Denmark landing most of the catches follows this regulation. This provision requires 1 sample per 2000 tonnes landed.

The majority of commercial catch and sampling data are submitted in the Exchange sheet v. 1.6.4 and further processed with the SALLOCL-application (Patterson 1998). This program gives outputs on sampling status and available biological parameters and documents actions

taken to raise unsampled metiers using other data sets. The species co-ordinator allocates samples of catch numbers, mean length and mean weight-at-age to unsampled catches using appropriate samples by gear (fleet) area quarter and if an exact match is not available then a neighbouring area if the fishery extends to this area in the same quarter.

B.2. Biological

Mean weights-at-age (g) in the catches have been very variable over time, but whether this is due to actual variation in mean weight or difficulties in ageing of sprat is uncertain.

No estimation of natural mortality is made for this stock.

B.3. Surveys

Acoustic estimates of sprat have been available from the ICES co-ordinated Herring Acoustic surveys since 1996. The estimated biomass of sprat has been very variable with low values in the period from 1997 to 2002, but recently the biomass has increased. The majority of the biomass during the acoustic survey is recorded in the Kattegat area.

The IBTS (February) sprat indices (no per hour) in Division IIIa are used as an index of abundance, however, the index has not been considered useful for management of sprat in Division IIIa. The indices are calculated as mean no./hr (CPUE) weighted by area where water depths are between 10 and 150 m (ICES 1995/Assess:13). The indices were revised in 2002 (ICES 2002/ACFM:12) based on an agreement in the IBTS WG in 1999, where it was decided to calculate the sprat index as an area weighted mean over means by rectangles for the IIIa (ICES 1999/D:2). The old time-series of IBTS indices (from 1984-2001) is shown in ICES 2001/ACFM:10.

Annex 1: TECHNICAL MINUTES

Herring Assessment Work Group (HAWG)

Vigo, 27 May 2005

Present:

Reviewers: Carmela Porteiro, Spain (Chair) Andre Forest (France) Jari Raitaniemi (Finland)

Chair HAWG::Mark Dickey-Collas

Observers

Pablo Abaunza (Spain) Santiago Cerviño (Spain) Julio Martinez (Spain)

General

The reviewers would like to acknowledge the effort made by the WG in compiling all the information and particularly to Mark Dickey-Collas for his excellent presentations on the different stocks and for the high quality of the Working Group report.

All together 10 stocks are considered; this year full analytical assessment has been carried out only for 3 stocks. For the rest, the assessment has either been updated or is experimental.

North Sea Autumn Spawners (NSAS)

The assessment was accepted as a good assessment (similar to last year).

The differences between official landings and the information provided by WG members (official figures are consistently lower across all years) were noted. Landings have been well above the TAC. The fact that misreporting is still substantial and has increased from last year (i.e. catch area misreported) was also noted.

The reviewers point out that landings abroad should be covered by the respective countries to be sure that biological data is collected.

The reviewers noted that the cohort of 2000 shows a significant decrease in mean weight-atage and also in the proportion of maturity comparing with the previous cohorts. It should be interesting to search for the possible causes, i.e. density –dependent effects or environmental aspects.,

The reviewers note that there is a sign of three poor year classes coming in after a period of good recruitment, although SSB is well above the precautionary biomass and F has stabilised over the last few years. It should be very useful to include a figure showing the contribution (proportion) of each year-class in the predictions.

The assessment is very well driven and it is based on a consistent catch matrix data and tuning surveys. The reviewers also appreciated the application of various assessment models for exploratory analysis. The reasons why the SURBA model gives a different trend in the last year

estimate of SSB and F, comparing with the results of ICA and XSA, could be explored with more detail.

The reviewers noted that the pattern in residuals show that the catch and surveys show different signals (Figure 2.6.1.1), and support the request for North Sea herring to be a benchmark assessment next year, to allow further exploration of these data.

The reviewers noted that generally the proposed harvest control rules meet precautionary criteria except however for the 15% limit in variation in TAC between years. Simulations showed that this was probably out side of the precautionary approach.

Downs herring (IVc and VIId)

The reviewers acknowledged the need for better understanding of the dynamics of the stock and welcomed the addition information provided this year.

The reviewers noted the lack of data available for this stock and the need for more historical information. Downs herring has shown independent trends in exploitation rate and recruitment but its current state is unknown.

It is a political stock component; it is important at least in some areas and the new information provided by HAWG in 2005 suggests that its importance as a source of North Sea production has increased recently.

Western Baltic Spring Spawners (WBSS)

The assessment for this stock is accepted (same as last year).

This stock is exploited jointly with NSAS, which implies the need for a mixed stock analysis. This analysis is well implemented.

The reviewers noted the lack of survey coverage of the whole stock at the same time, could be a problem and the Subgroup recommends the development of a single joint survey for this stock through PGHERS, in order to improve the efficiency of the indices. They also indicated the problem that juvenile herring from the North Sea stock has a feeding area in the Skagerrak and Kattegat. The residuals from surveys (IBTS and the two acoustic surveys) are very high and show year effects. The retrospective analysis shows some problems that could be investigated further. The selection pattern of the stock has changed through the assessment period.

It was noted that the relationships between the recruitment indices have improved although there is still some noise.

A figure showing the contributions by different cohorts to the projections would also be useful for this stock.

The reviewers noted that the mean weight-at-age is still decreasing and suggest that HAWG also prioritise the development of an annually varying maturity ogive for this stock as the adjacent stock of North Sea herring shows large inter-annual variability that can effect estimates of SSB and projections.

The review group were worried about the effect of using the current year's proportion of spawner types on the projections. A sensitivity analysis of this assumption would be of great benefit and the review recommends, now that a long time series is available, further exploration of the dynamics of the annually variation splits.

Celtic Sea and Division VIII herring

The stock is problematic, the assessment was not accepted but it was last year.

598 ICES Template Header

The reviewers note that the ICA model does not fit well in this case (specially no tuning data available for the assessment.).

The reviewers noted a change in the exploitation pattern from adults to juveniles in the recent years. The reviewers did not accept the description of this fishery as a recruitment fishery, and pointed out that it is just overexploited.

The review would like to have a description of the fleets that exploit this stock.

The reviewers hope the data from BTS UK-1q will be made available to the assessment group soon. The reviewers are worried about the low estimate of abundance given by the surveys in the last year.

Maturity at age is very variable and (is assumed to be) very different from North Sea stock.

Herring in the VIa North

Assessment was accepted last year. The assessment is the same as the last year. The stock has full reproductive capacity and is lightly exploited.

The reviewers note that the sampling coverage has been reduced significantly and that the problem of misreporting catches is still continuing. The mean weight-at-age from the acoustic surveys is the lowest of the time series available.

There was no clarity in the determination of F status quo, and unscaled mean averages appeared to have been used, rather than the final year or a scaled mean.

In the short term forecast it is observed that the TAC constraint option is not maintained through the three years forecast. It should be for the whole three years period of forecasting and not only for the first year.

The reviewers appreciate very much the initiative of designing a harvest control rule for this stock. However the conclusion of the simulations with regard to the possible range of candidate fishing mortalities produce some Fs that seem to be too close to F_{med} to be considered precautionary.

Herring in Divisions VIa (South) and VIIb,c

The state of the stock is unknown with respect to biological limits.

In the absence of tuning data, the assessments have been carried out by assuming various terminal F values on the catch-at-age data. Tuning indices are necessary to gain precision in estimates. The reviewers expect a preliminary exploration of an assessment with the acoustic tuning series next year.

The reviewers note that it is necessary to perform a yield per recruit analysis to obtain estimates of Fmax and F0.1.

Irish Sea herring (VIIa north)

The assessment for this stock was not accepted by the WG.

The reviewers acknowledge the effort in assessing this stock and a there has been an improvement in the assessment method but the results are still too imprecise especially when looking at the retrospective pattern.

It should be interesting to recover the index of abundance of the incoming year-classes from IBTS using otolith microstructure.

The reviewers appreciate the arguments given in section 1.10 on the approach to the western stocks and look forward to the results from WESTHER. Next year, in light of these new results the review group would like to see some exploration of the dynamics of the western stocks, within a metapopulation framework.

Sprat in the North Sea (Subarea IV)

The assessment is regarded as exploratory.

Due to the characteristics of the stock (short-lived species, with the stock dominated by 1-and 2-year olds and with unreliable numbers-at age from surveys and catches), Catch Survey Analysis (CSA) has been used for data exploration as it was used last year. The model results are very sensitive to M (the natural mortality, which is very difficult to estimate) and s (ratio of the survey catchability of the recruits to the fully recruited) parameters. The reviewers recommend that the new version of CSA (that has a subroutine to estimate s) be used in the future. The model is very sensitive to assumptions about M and these can be further explored with the new version.

The IBTS index shows a higher recruitment for the last year. The reviewers point out to include the information (i.e. number-at-age) from the IBTS and the acoustic survey in the report.

Sprat in Division IIIa

There is no assessment on this stock and its state is unknown.

It shows a high variability in the catches driven by the strength of the incoming recruitment.

The index of recruits used in the shot forecast was the total catch in numbers instead of the age 1 recruits.

Its exploitation is mainly controlled by the regulation of the herring fishery.
