## 2. TERMS OF REFERENCE

At the 71st Statutory Meeting, the Council decided (C.Res.1983/2:8:13):
"that the Arctic Fisheries Working Group should meet at ICES headquarters from 26 September to 3 October 1984 to:
(i) assess catch options for 1985 inside safe biological limits for cod and haddock in Sub-areas I and II,
(ii) analyse the effect of changes in the data sets of weight at age and age at first maturity on the time series of stock and spawning stock biomass.
3. NORTH-EAST ARCTIC COD
3.1 Status of the Fisheries
3.1.1 Landings prior to 1984 (Tables $1-3$ and Figure 5A)

The revised figure for total landings in 1982, 363730 tonnes, is 1139 tonnes less than the figure used by the Working Group in 1983 (Anon., 1984a), but 63730 tonnes in excess of the TAC. Provisional figures for 1983 indicate a further decline in the landings (Table 1), the total catch of cod in 1983 amounting to 290000 tonnes which is 18000 tonnes less than anticipated by the 1983 Working Group and close to the TAC of 300000 tonnes. From 1982 to 1983 the catches declined in all areas both for trawl and other gears. The most significant reductions were observed in the Norwegian catches by conventional gears in Sub-area I and Division IIa and in the total USSR fishery (Tables 2-3).
3.1.2 Expected landings in 1984 (Tables 1 and 2)

The total landings for 1984 were estimated to 279000 tonnes based on catch statistics for the first half of the year from Norway, USSR, Faroe Islands, Federal Republic of Germany, and on information on catch quotas for other countries. As seen in Table 1 , the landings in 1984 were expected to be distributed somewhat differently compared to 1982 and 1983. In Divisions IIa and IIb the declining trend is expected to continue, while landings from Sub-area I increase owing to higher vulnerability and larger catches of cod off East-Finnmark during spring and summer 1984.
3.1.3 Catch per unit effort (Tables 4-6)

The total trawl catches of cod and haddock combined and the total trawl effort (Norwegian units, Table 4) continued to decline in 1983 in all areas, but catch per unit of effort in the total trawl fisheries was maintained in Sub-area $I$, and only slightly reduced in Division IIa. For cod, the catch per unit of effort figures (Table 5) tended to increase in all areas from 1982 to 1983 except for the USSR fleet in Sub-area I. Catch per unit of effort data from the Lofoten fishery (spawning stock) are given in Table 6. In the past three years the figures for gillnets and longline/handline show opposite trends. This was explained in the 1983 Working Group Report (Anon., 1984a).
3.2 Catch in Numbers at Age (Table 15)

Age compositions for 1982 were revised using the same data base as the 1983 Working Group and taking into account revised landings. For 1983 the data available for calculating catch in numbers were:
(a) Landings by areas from each country for the whole year.
(b) Age compositions from the Norwegian catches in all three regions, age compositions from USSR catches in Sub-area I and Division IIa for the first half of the year (data submitted to the 1983 Working Group), age compositions from Spanish catches in Division IIb, and age compositions from the catches of the Federal Republic of Germany in Division IIa.

Catch in numbers at age for other countries were arrived at by using the USSR age composition in Sub-area I and the age composition from Norwegian trawl catches outside the 12 nautical mile limit in Division IIa. In Division IIb the age composition from Spanish trawlers was used for the Spanish and the USSR catches. Catch in numbers for Norway, Spain and USSR were summed, and the resulting age composition was used for the landings by other countries.

Catch in numbers for 1984 were calculated from the expected landings and age compositions for the first half of the year from Norway, USSR and the Federal Republic of Germany. Catch in numbers for other countries was arrived at by using the age compositions from Norwegian trawlers in Sub-area I and Division IIa. In Division IIb the USSR age composition was applied to all the expected landings.
3.3 Weight at Age (Tables 7-8)

Table 7 shows figures of mean length at age in the Norwegian winter surveys (Dalen et al., 1984). The values for 7 and 8 year old fish are not representative for the stock, since large portions of these age groups were on spawning migration and thus south of the area covered by the surveys. For 3-6 year olds the values show an increaing trend for all year classes following the 1975 year class. Data on weight at age in all the Norwegian surveys in 1982, 1983 and 1984 show a similar trend, and the figures deviate significantly from those used in previous assessments and which have been kept unaltered for many years. The Working Group, therefore, decided to use the Norwegian winter survey data on weight at age for 3-6 year olds in 1983 and 1984 as input weights in the stock these years. The "old" values were used for all age groups and all years prior to 1983 and for the 7 years and older fish in 1983 and 1984.

Data for the weight at age in the catches were available from Norwegian catches in 1983 and 1st half of 1984, and from Spanish catches in 1983. Weights in the USSR catches were calculated from the length at age data from 1 st half of 1983 and 1984 by applying the formula $W=0.9 \times \mathrm{L}^{3}$, which is the mean from the Norwegian and Spanish data for 1983. It was decided to use the weighted mean values of these data for the age groups 3-6 in 1983 and leave the older age groups unchanged.

The Norwegian survey data and the USSR length at age data from the catches show an average increase of $15 \%$ in weight at age for the age groups 3-7 from 1983 to 1984. The mean weights at age in the catches of 1984 were then calculated as the weights of 1983 raised by 1.15 for age groups 3-7, leaving the older ages unchanged. The weight at age data used in the VPA are shown in Table 8.

The recent increase in the differences in weight at age for the younger fish in the catches and in the stock may be explained by the shift in the fishing pattern. The heavy fisheries on younger age groups no longer persist owing to poor year classes and increased mesh sizes in trawls in the recent years.
3.4 Age at Maturity (Table 9)

Prior to 1981 the Working Group had taken the mature part of the stock to be all fish of age 8 and older. In 1982 the Working Group consi-
dered, however, that it would be more realistic to use a maturity ogive.

An analysis of the published maturity ogives indicated that during the last 40 years (1942-81) there had been a slight trend of decreasing age at first maturity (Anon., 1983). Therefore, in 1982 the Working Group introduced a series of ogives which reflected the observed trend.

For the period 1980-82 there was a large difference between data supplied by Ponomarenko (1982) and by Hylen and Nakken (1982). It is not clear whether the differences in these two data sets were due to methodology or to a real change in maturity in 1982, but the Working Group was aware of the sampling problems which Ponomarenko had faced in obtaining accurate maturity ogives from trawl catches only. These problems were to a certain extent solved by the Hylen and Nakken method.

The Working Group decided in 1983 to apply two approaches in calculating spawning stock biomass. As Alternative 1, the spawning stock biomass was calculated with maturity ogives given by Hylen and Nakken, using the 1982 data for the period 1946-82 and the ogive derived in 1983 for that year and for the prediction period (Table 9). As Alternative 2 the 1982 approach was continued, applying the average of the Ponomarenko and Hylen and Nakken data sets for 1982 and using an average, giving double weight to the Ponomarenko data for 1981, 1983 and for the prediction period.

The Working Group recommended in its 1982 and 1983 reports that age at maturity data for earlier years should be made available for each single year in order to make a detailed analysis of the maturity ogives in the past. No additional data were made available to this meeting for the years prior to 1982 and no new analysis of the maturity ogives in earlier years could be carried out. A maturity ogive for 1984, obtained from survey data (Dalen et al., 1984, Godø et al., 1984a and Godø et al., 1984b) by applying corrections for fishing between survey time and 1 January was given by Hylen and Nakken (1984).

The Working Group decided therefore to calculate spawning stock biomass for the period 1982-84 using the respective ogives given by Hylen and Nakken for these years (Table 9). None of these ogives could be applied to the previous years with any confidence, and it was decided to use a knife-edge maturity ogive (fish 8 years and older as mature) for the entire period prior to 1982 , as used also by the Working Group in its reports before the 1982 report. For the prediction period, the 1984 maturity ogive was applied.

### 3.5 Survey Results

Survey results which had become available since the 1983 Working Group meeting were:

The Joint Norwegian-USSR 0-Group Survey in August-September 1984 (Anon., 1984b).

The Barents Sea Acoustic and Bottom Trawl Survey in February 1984 (Dalen et al., 1984).

The Svalbard Bottom Trawl Survey in September 1983 (Godø et al., 1984a).
The Spawning Ground Acoustic Surveys (Godø et al., 1984b). Evaluation of the Norwegian Survey Results (Hylen and Nakken, 1984).

In addition, members of the Working Group had information on the preliminary results of the USSR bottom trawl survey during the winter 1983-1984.
3.5.1 O-Group surveys (Table 10)

The abundance indices for the year classes 1982, 1983 and 1984 are all larger than any of those from the period 1976-1981 and the two last years' figures are only exceeded by that of the 1970 year class.

### 3.5.2 The bottom trawl surveys (Tables 11 - 13)

In the Norwegian surveys the indices for all year classes show an increasing trend during the first 3-5 years of the life of the fish, probably caused by a lower availability to the trawls by the smaller specimens (Dalen et al., 1984).

The indices from the 1984 bottom trawl survey in the Barents Sea (Table 11) for the year classes prior to 1981 were in agreement with previous results, indicating that the 1980 year class in this area was slightly less abundant than the preceding ones. The index for the 1981 year class which in the two previous years was quite low, showed an unexpected high increase from 1983 to 1984 , probably due to difficulties in the separation of 2 and 3 year old fish in the 1984 survey. In the Svalbard area (Table 12) both the 1980 and the 1981 year classes seemed to be less abundant than the previous ones, particularly the 1979 year class.

Both the 1982 and the 1983 year classes were far more abundant in the 1984 (and 1983) bottom trawl surveys than the preceding year classes, thus confirming the results of the 0-group surveys.

### 3.5.3 Acoustic surveys (Table 14)

Details of the acoustic surveys in 1984 are given in the respective survey reports and in Hylen and Nakken 1984 where the surveys are also evaluated.

The acoustic estimates of abundance for 3-7 year old fish in the eastern part of the Barents Sea were considerably increased from 1983 to 1984. In this area, the 1984 estimates for these age groups were suspected to be overestimates due to a combined effect of high echo abundance from the 1982 and 1983 year classes and the lower catchability of these small fish (Dalen et al., 1984). The acoustic surveys of the spawning grounds in $19 \overline{84}$ indicated spawning stock size about $20 \%$ below that found in 1983 (Godø et al., 1984b).

The acoustic abundance estimates of 1 and 2 year old fish in the 1984 Barents Sea survey supported the observations from the 0-group and bottom trawl surveys: The 1982 year class was considerably more abundant than the preceding year classes, while the acoustic estimate of the 1983 year class as 1 year olds was the highest ever obseryed since the surveys started in 1976.

### 3.5.4 Evaluation of the surveys

Hylen and Nakken (1984) evaluated the Norwegian survey results for 1984 (and 1983). They discussed the sources of errors affecting the results and found: "The most serious of these errors was the upward bias of the acoustic estimates of age group 3 and older fish in the eastern Barents Sea. In this area large quantities of 1 and 2 year old fish made up the bulk of the echo abundance, but since the trawl catches oversample the larger fish and the length distributions from the catches are used directly in the conversion of echo abundances for fish densities, the older age groups (3+) were overestimated. We have, therefore, neglected the acoustic estimates for the eastern Barents Sea and estimated the number of fish in each age group in this area this way:

$$
\mathbb{N}_{1984}=\frac{\mathbb{N}_{1983}}{\mathrm{IND}_{1983}} \cdot \mathrm{IND}_{1984}
$$

$\begin{aligned} \text { where } & \mathrm{N}_{1983} \\ \mathrm{IND}_{1983} & \text { is the acoustic estimate in } 1983 \\ \mathrm{IND}_{1984} & \text { is the bottom trawl index in } 1983 \\ & \end{aligned}$
This estimator simply expresses the assumption that the ratio between acoustic estimates and bottom trawl indices for each age group were equal in 1983 and 1984".

Hylen and Nakken used the corrected acoustic estimates together with estimates from the other cruises and the landings in 1984 to assess the total stock and the spawning stock per 1 January 1984. Their results are presented in Table 14, where also the results from the two preceding years appear. In general, the results of the 1984 surveys confirmed the impression from the bottom trawl survey and the 0-group survey:

The estimate of 4 year olds and older fish fitted reasonably well with the previous years' observations while the estimate of 3 year olds ( 1981 year class) seemed high, and the two youngest year classes (1982 and 1983) were far more abundant than any of the preceding ones.

Particularly the 1983 year class seemed strong and was estimated to 2400 million individuals at age 1.
3.6 Recruitment (Tables 17 and 18, Figures 4 and 5C)

A summary of the information available from the surveys on the year classes 1981-1984 is given in the text table below.
0 -group index
1 year, bottom trawl index
2 year, bottom trawl index
1 year, acoustic, $N \cdot 10^{-6}$
2 year, acoustic, $N \cdot 10^{-6}$

| 1981 | 1982 | 1983 | 1984 |
| :---: | :---: | :---: | :---: |
| 0.10 | 0.59 | 1.69 | 1.55 |
| 0.1 | 45 | 355 |  |
| 6 | 127 |  |  |
| 1 | - | 2400 |  |
| 15 | 506 |  |  |

The 0-group indices indicate that the 1983 and 1984 year classes were about 3 times as abundant as the 1982 year class. The bottom trawl indices indicated a 1983 year class which was 8 times stronger than the 1982 year class, while the acoustic survey indicated a ratio of 4:1 between the 1983 and the 1982 year classes when a reasonable natural mortality coefficient was accounted for.

The 1982 year class was estimated to about 400 million specimens at age 3 both from the relationship in Figure 4 and from the acoustic estimate of 2 year old fish when applying an annual natural mortality coefficient of 0.2. The 1983 year class was estimated to 1000 and 3200 million individuals at age 3 , using the 0 -group index and the bottom trawl index respectively, and 1500 million individuals when projecting the 1 year acoustic estimate. The Working Group therefore agreed on an estimate of 3 year old fish of 1500 million individuals in the 1983 year class. The abundance of the 1984 year class was also set to 1500 million individuals giving more weight to the ratio between the 1983 and 19840 -group indices (1:1) than to the values obtained from the relationship in Figure 4.

### 3.7 Fishing Mortalities - VPA Runs

A preliminary VPA was run using input $F$ values for 1984 based on the 1983 exploitation pattern from last year's Working Group Report scaled to $\bar{F}_{5-10}=0.55$ to match the expected catch in 1984. A comparison with the stock estimates from the acoustic survey showed a good agreement for some age groups and it was evident that relatively minor changes in the input $F$ values would improve this agreement. An evaluation of the total stock based on the acoustic survey has been made only since 1982 and the addition of 1984 as the 3rd year in this series means that the reliability of the survey data is better established and that more information is available for tuning the VPA to the survey results. A new series of input Fs based chiefly on the survey results were used in a VPA and the text table below shows the VPA stock number estimates 1982-1984 compared with those from the acoustic survey.

| Age | 1982 |  | 1983 |  | 1984 |  | F |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Stock Number (millions) |  | Stock Number (millions) |  | Stock Number (millions) |  |  |
|  | Survey | VPA | Survey | VPA | Survey | VPA |  |
| 3 | 87 | 137 | 29 | 67 | 121 | 63 | . 06 |
| 4 | 105 | 135 | 81 | 104 | 58 | 52 | . 25 |
| 5 | 103 | 99 | 99 | 92 | 59 | 68 | . 45 |
| 6 | 95 | 81 | 58 | 64 | 54 | 57 | . 60 |
| 7 | 154 | 91 | 43 | 41 | 30 | 37 | . 70 |
| 8 | 23 | 15 | 50 | 37 | 19 | 19 | . 60 |
| 9 | 12 | 5 | 13 | 5 | 12 | 14 | . 50 |
| 10 | 1 | 2 | 5 | 1 | 4 | 2 | . 50 |

The agreement is generally good for the age groups 5-7. The high survey estimate of 7 -year-old cod in 1982 is explained by the special behaviour of that year class during the 1982 survey (Hylen and Nakken, 1983). Excluding this year class, a linear regression of the survey and the VPA results for age groups 5-7 in 1982-1984 gives a correlation coefficient of 0.97 . This demonstrates that a high correlation between VPA and survey results can be obtained with input $F$ values that appear to be at a reasonable level. For age group 4 , the acoustic survey tends to give underestimates, usually of about 20 per cent, and the 3-year-old cod is also usually underestimated, although 1984 for special reasons deviates from this pattern (Dalen et al., 1984). From age 8 or 9 the survey tends to produce overestimates compared to the VPA. The reason for this is not clear. Figure 1 shows the fishing mortalities generated by other gears than trawl for the 8-12 year olds.

Plots of fishing mortality generated by Norwegian trawlers versus effort by the same fleet are presented for age groups $5-6$ combined in Sub-area I (Figure 2) and age groups 5-8 combined in Division IIa (Figure 3). The effort in 1984 is estimated on the basis of data from only part of the whole year's trawl fishery, and especially in Sub-area I this fraction is very low. The Working Group therefore felt that no great reliance could be put on the 1984 values. In the plots, the points representing the most recent years are mostly above the regressed line and this indicates an increase in catchability. Plots showing catchability ( $Q=F / E f f\left(\begin{array}{rl}\end{array}\right)$ versus year are therefore included on Figure 2 and Figure 3. Both catchability plots show an increasing trend, but the increase appears to be more rapid in the period 1980-1983 than in the 1970's. This is not unreasonable, considering that Norwegian trawlers have been severely restricted by quotas in the $1980^{\circ} \mathrm{s}$, and therefore may have tended to choose the grounds and seasons which give the highest catch rates. Unfortunately, the trend in catchability in the most recent years indicated by the plots is highly dependent on the input F values in the VPA. There is no independent information that can be used to give a reliable estimate of this trend and the plots are therefore at this stage of no practical use in estimating input Fs for the VPA.

In view of the lack of reliable data from other sources, the Working Group agreed that the assessment should be based primarily on the acoustic survey results. The input $F$ values given in the text table are therefore used in the final VPA. For the age groups 5-8 the Fs were chosen to produce stock numbers close to those estimated in the survey. For age 4, the usual underestimate in the survey was taken into account and the Working Group also felt that it was reasonable to expect that the increased weight at age 4 observed in 1984 would give an increase in the fishing mortality compared to the most recent years. F at age 3 was chosen to make the 1981 year class approximately the same size as the 1980 year class, as other information indicates (Tables $10-13$ ). For age 9, the survey results indicate that the fishing mortality should be lower than for age 8 ( $F 8=0.6$ ) and a value of 0.5 was chosen for the age groups $9-13$, and 0.45 for the age groups 14-15+.

The fishing mortalities in the VPA are shown in Table 16 and the VPA stock numbers in Table 17 and Figure 5A. The fishing patterns show a shift towards younger fish from 1983 to 1984 but the exploitation
remains at the same level. This is a reduction of about $20 \%$ compared to the period 1979-1982. The historic trend in fishing mortality is shown in Figure 1 and in Figure 5B.

### 3.8 Short-term Projection of Stock Biomass and Catch

In Table 18 the input for the catch and stock biomass predictions are given. The natural mortality, maturity ogive, and weight at age in catch and stock are those used for 1984 in the assessment.

The Working Group expected the rich 1982-1984 year classes to be more heavily exploited at age 3 and 4 than the preceding ones. The $F$ values for these age groups were therefore increased by approximately 0.1 giving the fishing pattern in Table 18.

The input number of 3 year old recruits were taken to be 400, 1500 , and 1500 million individuals for the 1982, 1983, and 1984 year classes respectively (see 3.6 ).

Projections of catches in 1985 and stock size at 1 January 1986 are given in Figure 6. The yield per recruit curve is shown in the upper part of the figure. $F_{\max }=0.33$ compared to a current level of $\bar{F}_{5-10}=$ 0.56. Management options for 1985 are given in the text table below.

## MANAGEMENT OPTIONS

Species: NORTH EAST ARCTIC COD
Area : ICES Sub-areas $I$ and II

| 1984 |  |  |  | Management option for 1985 | 1985 |  |  |  | 1986 |  |

Weight in thousand tonnes
*Expected catch estimated by the Working Group
3.9 Medium-term Projection of Stock Biomass and Catch

Also for the medium-term projection, the 1984 values for the weight-atage in the catches and in the stock were used. It should be noted that slower growth of the strong year classes 1983-1984 would give lower estimates of catches and stock biomass for 1986, and especially for 1987, than those presented. An increase in the exploitation on the younger age groups is also likely to produce lower catch weights for these age groups.

The following text table shows the development of the spawning stock for 5 alternatives of fishing strategy in the period 1985-1987. The total biomass and catches for 1988 and 1989 are not given in the table because of the uncertainty of the growth of the 1983 and 1984 year classes and the unknown recruitment of 3 year old fish in these years.

NORTH EAST ARCIIC COD.

STB : Stock biomass
SSBI : Spawning stock biomass using maturity ogive for 1984
SSBII: Spawning stock biomass as for SSBI except fish of the 1983-1985 year classes.

All alternatives give two sets of figures for the spawning stock biomass in 1987-1989. One set - SSBI - shows the values arrived at when applying the maturity ogive used for 1984 to the whole period. The alternative SSBII - shows the spawning stock biomass when all fish of the 1983 and 1984 year classes at ages 6 years or less were removed from the spawning stock. The reason for presenting these two alternatives was that the Working Group considered it unlikely that the two last years' strong year classes with distribution areas extending far to the east and north in the Barents Sea, would become mature at a rate similar to that observed during the past 3 years.

All alternatives of fishing strategy result in a spawning stock level in 1986 below that of 1985, the 1986 level being 186 and 297000 tonnes for catches in 1985 of 350000 tonnes and 170000 tonnes, respectively. In 1987 and 1988 , the spawning stock biomass increases for 4 of the alternatives, but continue to decrease if the fishing mortalities in 1985 and 1986 are kept similar to those in 1984 and if the 1983 and 1984 year classes do not contribute to the spawning stocks. Bearing in mind the differences observed in maturity ogives for cod during the past 30 years (Anon., 1983), the Working Group was of the opinion that Alternative 5 should not be chosen since this may result in a spawning stock in the late 1980's, which is about half the present level. The spawning stock levels of $350000-400000$ tonnes in 1983/1984 have produced rich year classes and the Working Group, therefore, consider Alternative 4 ( $\mathrm{F}_{\max }$ ) as the better as far as future recruitment is concerned.

### 3.10 Stock and Recruitment Relationship

In its last report (Anon., 1984a), the Working Group made plots of parent stock and number of 3 year olds for the period 1946-1976 for two alternatives of spaming stock. The differences in the spawning stocks arrived at by the two alternatives are large (see discussion in 3.4). The main use of a stock/recruitment relationship would be to determine a minimum level above which the spawning stock should be maintained in order to safeguard recruitment. The Working Group found it extremely difficult from the amount of information available up to now to decide on such a minimum level, because of the uncertainties encountered regarding parent stock size in the past. Diurnal measurements of the spawning stock exist only for the last three years, 19821984. In these years, the spawning stock biomass was estimated to 400000,380000 , and 370000 tonnes respectively, and year classes of fair and strong abundance have been produced. Until information is available which permits the calculation of more precise figures for the spawning stock in the past, the Working Group recommends that effort should be made to keep the spawning stock as close to the level of 1982-1984 as possible, or higher.
4. NORTH-EAST ARCTIC HADDOCK
4.1 Status of the Fisheries (Tables 19-20, Figure 9A)

### 4.1.1 Landings prior to 1984

The revised figure for total landings in 1982, 46955 tonnes, is about 300 tonnes less than the figure used by the Working Group in 1983
(Anon., 1984a). Provisional figures for 1983 showed a further decline in the catches of haddock both in Sub-area I and in Division IIa. The total catch in 1983 of about 22000 tonnes is well below the figure of 27000 tonnes estimated by the 1983 Working Group.

### 4.1.2 Expected landings in 1984 (Table 19)

Based on information about landings in the first half of the year from Norway, USSR, Faroe Islands and the Federal Republic of Germany, the Working Group estimated the landings in 1984 to be approximately the same as in 1983. However, since a significant part of the haddock catches are now taken in the Norwegian coastal fishery in autumn, the landings for the whole year are difficult to estimate.
4.1.3 Catch per unit of effort (Table 21)

Cpue in the Norwegian fisheries showed a sharp decline from 1982 to 1983, both in Sub-area I and Division IIa, the 1983 figures being only half the 1982 figures.
4.2 Catch in Numbers at Age (Table 24)

Age compositions for 1982 were revised using the same data base as the 1983 Working Group and taking into account the revised landing figures. For 1983, the data available for calculating catch in numbers at age were:
(a) Landings by areas from each country for the whole year;
(b) Age compositions from the Norwegian catches, age compositions from the USSR catches in Sub-area I and Division IIa for the first half of the year (data submitted to the Working Group in 1983), age compositions from the Federal Republic of Germany catches in Division IIa.

Catch in numbers at age for the landings of other countries were arrived at. by using the age compositions from Norwegian catches in Sub-area I, age compositions from Norwegian trawl catches outside the 12 nautical mile limit in Division IIa, and age compositions from Norwegian trawl catches off East Finnmark in Division IIb. For 1984, the catch in numbers at age were calculated from the expected landings and the age compositions for the first half of the year from the Norwegian catches in the respective areas, following the scheme used for the 1983 data.

### 4.3 Weight at Age

In the 1983 Working Group report, the same set of weights was used for both catch and stock. There was no evidence indicating significant changes in the stock weights, which therefore have been kept unchanged.

In the most recent years, an increasing part of the catches have been taken by Norway which in 1984 is expected to account for about $90 \%$ of the landings. This has led to changes in the catch weights and the Working Group felt that it would be most appropriate to use the weight-at-age data from the Norwegian landings in 1983 as catch weights in 1983, 1984 and for the predictions. The catch and stock weights are shown in Table 27.
4.4 Age at Maturity (Table 27)
Only two maturity ogives (Sonina 1981, and Sætersdal 1954) were avail-
able for haddock at the Working Group meeting in 1983. No additional
data were made available to this meeting, so therefore the Working
Group decided to apply the standard maturity ogive established last
year (Sætersdal 1954) for the whole period and for the prediction
period.
4.5 Survey Results
The survey information that was used originated from the same surveys
as for cod (see Section 3.5).

### 4.5.1 0-group surveys

Table 22 shows the 0-group indices for haddock. In the last three years, the indices have increased considerably compared with the period 1977-1981, the index for 1984 being the highest observed since the 0group survey started.

### 4.5.2 Bottom trawl surveys (Table 23)

The abundance indices from the Norwegian bottom trawl surveys in the Barents Sea in February are shown in Table 23. The indices for the year classes prior to 1982 are all low and their confidence limits rather high (Dalen et al., 1984). As for cod, it is thought that the index of 15.2 for the 1981 year class as 3 -year-olds is an overestimate. The indices for the 1982 and 1983 year classes are much higher than those for the preceding year classes, thus confirming the results from the 0 -group surveys, and also indicating a similar ratio for year class strength between these two year classes (1:2) as do the 0-group indices.

### 4.5.3 Acoustic surveys

Acoustic estimates of haddock are given by Dalen et al. (1984). The estimates for the year classes prior to 1982 are all low, showing 1015 million 4 -year-old fish in the 1978-1980 year classes. The estimate for the 1981 year class as 3 -year-olds (in 1984) was probably biased upwards for the same reasons as for cod.
In the 1984 acoustic survey, the 1982 and 1983 year classes were estimated to 1000 million and 2100 million individuals, respectively.

### 4.5.4 Evaluation of the surveys

The estimates and indices arrived at for the year classes prior to 1982 were very low and variable both for the bottom trawl and for the acoustic surveys. The maximum information that can be extracted from the figures is that these year classes, 1978-1981, at an age of 3 years probably constituted $10-25$ million specimens, taking into account that the acoustic estimates for this age group tend to be an underestimate - at least for cod.
The estimates for the 1982 and 1983 year classes are in good agreement with the results from the 0-group and bottom trawl surveys. However, Nakken and Ulltang (1982) showed that the acoustic surveys of the 1975 year class tended to overestimate haddock and underestimate cod at ages 2, 3 and 4. The acoustic estimates of the youngest age groups should therefore be used with care.

### 4.6 Recruitment (Tables 26 and 27, Figure 9C)

Information available on the abundance of the recruiting year classes 1982, 1983 and 1984 is:

|  | Year class |  |  |
| :--- | :---: | :---: | :---: |
| 0-group index | $\frac{1982}{0.38}$ | $\frac{1983}{0.62}$ | $\frac{1984}{0.78}$ |
| 1-year, bottom trawl | 315 | 663 |  |
| 2-year, bottom trawl | 356 |  |  |
| 1-year, acoustic | - | 2 | 148 |
| 2-year, acoustic | 1002 |  |  |

The figures for the 0-group and the bottom trawl surveys are abundance indices and those for the acoustic surveys are given in millions of individuals. Looking at Table 22, it appears that only one single year class, the 1969 year class, has recruited more than 1000 million individuals at age 3 , while several year classes have amounted to about 300 million individuals at this age. The figures above indicate the following ratios between the abundance of the three year classes:

$$
\begin{array}{lll}
\frac{1982}{1} & \frac{1983}{1.5} & \frac{1984}{2.0}
\end{array}
$$

A natural mortality coefficient of 0.2 was applied in order to compare the two acoustic estimates. On the basis of these considerations, the Working Group decided to use figures for the 3 year olds in these three year classes as follows:

$$
\frac{1982}{200} \quad \frac{1983}{300} \quad \frac{1984}{400}
$$

where the figures are in millions of individuals.

### 4.7 Fishing Mortalities - VPA Runs

A preliminary VPA was made using input F values for 1984 based on the 1983 exploitation pattern from last year's Working Group Report scaled to $\mathrm{F}_{4-7}=0.20$ to match the expected catches in 1984. With the current low stock size, 0-group indices and survey results are of limited values in estimating the size of the most recent year classes in the VPA. In an adjusted VPA, the exploitation pattern was changed slightly to correspond better to that of the years 1980-1982 except that the $F$ at ages 3 and 4 were set relatively higher to give a better agreement between surveys and VPA for the year classes 1980 and 1981 (Tables 22 and 23). Apart from this, it could only be concluded that the trial VPA was not inconsistent with the other information.

The adjusted VPA shows a sharp decline in fishing mortalities after 1982 to a level in 1984 of about half the level in 1980-1982. Normally a majox part of the haddock is taken as by-catch in the fisheries for cod. Therefore, comparison between fishing mortality, catch per unit of effort and biomass for these two species is thought to
allow conclusions to be drawn for haddock based on the cod assessment. In Figure $7, \bar{F}_{6-7}$ generated on cod by Norwegian trawlers in Division IIa is plotted against $\bar{F}_{5-7}$ generated by the same fleet on haddock. In Figure 8, the ratio of the biomasses (3+) of cod and haddock is plotted against the ratio of total international trawl catches of cod and haddock.

In both plots, the scatter of points is too large to allow accurate estimation of the current fishing mortality level on haddock. However, in both cases the 1984 point is close to the regressed line and since there is no other information on the level of exploitation in 1984, the trial VPA was accepted as the final.

The fishing mortalities and stock numbers from the haddock VPA are given in Tables 25 and 26. The historic trend in fishing mortality is given in Figure 9B.
4.8 Short-Term Projection of Stock Biomass and Catch

In Table 27 are given the different input data used in the 1985 and medium-term projections. As mentioned earlier, the weight-at-age in catches were revised for 1984. This weight-at-age series is also used for 1985 . Also, the 1984 fishing pattern is assumed for 1985. These data do not give an $F_{\max }$ value on the yield per recruit curve as can be seen in Figure 10, Alternative 1. $F_{0.1}$ is almost equal to F1984. Therefore, only one.option is given for the short-term projection presented in the table below.

MANAGEMENT OPTIONS
Species: HADDOCK
Area : ICES Sub-areas I and II

| 1984 |  |  |  | Management option <br> for 1985 | 1985 |  |  |  | 1986 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Stock biom. (3+) | Spawn. stock biom. | $\bar{F}_{(4-7)} \begin{array}{r} 1) \end{array}$ | $\begin{aligned} & \text { Catch } \\ & (3+) \end{aligned}$ |  | Stock biom. (3+) | Spawn. stock biom. | $\bar{F}_{(4-7)}$ | $\begin{aligned} & \text { Catch } \\ & (3+) \end{aligned}$ | Stock biom. $(3+)$ | Spam. stock. biom. |
| 110 | 62 | . 25 | 21 | $F_{1984}=F_{1985}$ | 229 | 58 | . 25 | 47 | 434 | 66 |

1) $\mathrm{F}_{0.1}=0.23$
4.9 Medium-Term Projection of Stock Biomass and Catch

For the medium-term projection, several alternatives are given. Alternative 1 is the same as in the short-term projection. The Working Group expects that the strong 1982, 1983, and 1984 year classes will be more heavily exploited than the previous ones. The fishing mortalities are therefore increased with 0.1 for ages 3 and 4 are presented as Alternative 2. There is no $F_{\max }$ on the yield per recruit curve for this alternative either.

On the basis of stronger year classes and heavier fishing, the Working Group also considers a third alternative with the weight in the catch reduced to the same level as the weight in the stock. This represents
a change of weights for 3,4 , and 5 year olds. Together with the expected fishing pattern, this gives an $F_{\text {max }}$, as seen in Figure 10, Alternative 3. This $F_{\max }$ is almost the same as the expected $\bar{F}_{4-7}$ in 1985, and this alternative is presented in the projection table. Also $\mathrm{F}_{0.1}$ for the same situation is given as alternative 4.

North-East Arctic HADDOCK. Projections of stock and spawning stock biomass and catch.

| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Management strategy | $\begin{aligned} F_{84} & =0.24 \\ \left(F_{0.1}\right. & =0.23) \end{aligned}$ |  |  | $\bar{F}_{4-7}=0.31$ |  |  | $\begin{aligned} \bar{F}_{4-7} & =0.31 \\ \left(\mathrm{~F}_{\max }\right. & =0.34) \end{aligned}$ |  |  | $\mathrm{F}_{0.1}=0.19$ |  |  |
| Year | SB | SSB | Catch | SB | SSB | Catch | SB | SSB | Catch | SB | SSB | Catch |
| 1985 | 229 | 58 | 47 | 229 | 58 | 75 | 229 | 58 | 42 | 229 | 58 | 27 |
| 1986 | 434 | 66 | 101 | 415 | 64 | 166 | 415 | 64 | 89 | 434 | 70 | 62 |
| 1987 | 737 | 109 | 181 | 664 | 94 | 260 | 665 | 94 | 148 | 728 | 114 | 106 |
| 1988 |  | 203 |  |  | 162 |  |  | 162 |  |  | 212 |  |
| 1989 |  | 340 |  |  | 256 |  |  | 256 |  |  | 361 |  |

1. Fishing pattern and fishing mortality as applied for 1984. Expected weight-at-age data.
2. Expected fishing pattern and weight-at-age data. Fishing mortalities in 1984 adjusted for the change in the 1984 fishing pattern.
3. Expected fishing pattern. Fishing mortalities as in 2. Weight-at-age data the same as used in 1983 by the Working Group (Anon., 1984).
4. Expected fishing pattern and weight-at-age data as in VPA.

The stock and catch predictions for 1988 and 1989 are not given. because the estimates are considered to be very uncertain.

The spawning stock biomass of haddock is currently at a low level, and a significant increase will not occur until 1987, when about 25 per cent of the 1982 year class is expected to reach maturity. Also, the current low level of fishing mortalities means that a relatively large change in exploitation is needed to make a significant difference to the spawning stock biomass in 1986, even in relative terms.

The spawning stock biomass in 1987 will also be relatively insensitive to the 1985 TAC. For the long-term development in the spawning stock biomass, changes in the exploitation pattern may be much more crucial than the 1985 TAC.

## 5. DEFICIENCES IN DATA BASE

The deficiences in the data base were:
(a) Lack of age compositions from other countries than Norway, USSR, Spain and Federal Republic of Germany.
(b) Lack of age compositions for the second half of 1983 from USSR fisheries.
(c) Lack of weight-at-age data for years prior to 1982. Such data should always be given together with the age compositions.
(d) The results from the USSR bottom trawl surveys 1983-1984 should have been made available.
(e) Insufficient knowledge of the rate of maturation in years prior to 1982. The use of the published information produces a time series of the spawning stock which does not seem reasonable. Reliable information on maturation rates in the past is essential both for a stock and recruitment relationship and for the prediction of the spawning stock.
