### 1.2 Terms of Reference

At the Statutory Meeting in 1989 it was decided (C.Res.1989/ 2:4:10) that the Industrial Fisheries Working Group (Chairman: Mr H. Gislason) should meet at ICES Headquarters from 20-27 March 1990 to:
a) consider the Report of the Multispecies Assessment Working Group;
b) estimate monthly quantities and quarterly geographical distribution and size composition of by-catches of herring, cod, haddock, whiting, mackerel, and saithe taken in the fisheries for Norway pout, sandeel, and sprat in the North Sea and adjacent waters and report them to the relevant assessment Working Groups;
c) assess the status of the stocks of the target species in the industrial fisheries, i.e., sprat in Sub-area IV and Divisions IIIa, VIa, and VIId,e and Norway pout and sandeel in Sub-area IV and Divisions IIIa and VIa;
d) provide quarterly catch-at-age and catch and stock mean weight-at-age data and information on the relative distribution at different ages by quarter for North Sea stocks for 1989 as input for the multispecies VPA.

In addition, the Working Group was requested by ACFM (minutes of ACFM meeting 23-31 May 1989) to:

1) Look at the definition of "industrial landings";
2) Look into whether there is a case for combining the North sea and Division IIIa assessments for Norway pout.

These two subjects are covered by sections 1.6 and 4.2 , respectively.

### 1.3 Data Deficiencies

The number of samples obtained from the Danish industrial fishery decreased in 1989 compared to 1988. The decrease was mainly due to an increase in the number of fishermen who refused to have samples collected from their catch.

### 1.4 Assessment Programs

At the previous meeting, the working Group tried with varying success to apply Laurec-Shepherd tuning on annual data in the assessments of Norway pout and sandeel in the North sea. The problems encountered with this approach were thought to be due to the poor convergence of the VPAs, which makes the estimated fishing mortalities very dependent on the input fishing mortalities for the oldest age group. In addition, the high levels of natural mortality make the seasonal distribution of the catch within the year important.

This year a program for tuning on quarterly or half-yearly data was made available to the Group by P.A. Kunzlik. The program uses the same algorithm as the ICES program to provide the terminal fishing mortality in the most recent year. At its present state of development it is only able to handle one fleet at a time and may only use data from a single quarter/half-year. However, considering the drawbacks of using the annual program for highly seasonal fisheries on short-lived species, the Working Group decided to use the quarterly/half-yearly program. The program and input data as well as a short manual are available at ICES Headquarters.

Using a semi-annual or quarterly program does, however, not solve all problems. In most cases the estimated catchabilities are highly variable, which makes the estimated fishing mortalities for the terminal year sensitive to whether the option for using log catchability is chosen or not. The working group decided, as recommended by ACFM, to use logged catchability even though it was realised that this approach differs from the approach used in previous reports where the input $F$ was assumed to be directly proportional to effort.

For North Sea sandeel in particular, one further problem is evident. In previous years it has been noticed that the fishery seems to be able to fish selectively on strong year classes. If this is the case, one of the assumptions behind the ad hoc tuning is violated. One way of getting around this problem could be to make catchability a function of abundance. Due to lack of time this idea could not be pursued further.

### 1.5 The Report of the Multispecies Assessment Working group

The report of the Multispecies Assessment Working Group was briefly discussed and it was noted that, except for Norway pout at age 1 , the estimated total natural mortality at age is in accordance with the values used by this Group.

For Norway pout, a comparison between estimates of stock size and IYFS indices at age 1 revealed that the MSVPA estimates were in slightly better agreement with the IYFS than the single-species VPA estimate of last year's assessment (Anon., 1989a, Table 4.4.4). These relationships are shown in Figure 1.5.

A RCRTINX analysis using the IYFS, EGFS, and SGFS indices with linear downweighting of earlier years and estimates shrunk towards the mean revealed that both the internal and external
standard error of year-class strength predictions decreased by approximately $25 \%$ on average if MSVPA rather than VPA estimates were used.

### 1.6 Definition of Industrial Fisheries

In 1983, the Industrial Fisheries working Group adopted the following definition of industrial fisheries: "The usual definition of industrial fisheries is that these are fisheries with smallmeshed gear for reduction purposes" (Anon., 1983).

In terms of the present Working Group, industrial landings by definition derive from industrial fisheries with small-meshed trawl only. Industrial landings, therefore, do not include:

- Fish landed for industrial purpose from other gears than small-meshed trawl.
- Fish caught by small-meshed trawl but landed for human consumption.
- Fish caugtht for human consumption but due to market conditions used for industrial purpose.

However, for the species for which which this Working Group is asked to provide assessments, i.e., sprat, sandeel, and Norway pout, total catches are used.
since 1983, the above definition has been strictly adhered to, except for 1985 when some quantities of herring caught by purse seine were included, because parts of these landings had been used for reduction purposes.

## 2 TRENDS IN THE INDUSTRIAL EISHERIES FOR SANDEEL, SPRAT, AND NORWAY POUT IN DIVISION IIIA, THE NORTH SEA, AND DIVISION VIA

### 2.1 Division IIIa

The annual landings from the industrial fisheries for the years 1974-1989 are given in Table 2.1. The total landings appear to have oscillated around a long-term mean of $173,000 \mathrm{t}$ without any particular trend. They decreased from 151,000 t in 1988 to 92,000 $t$ in 1989. The long-term declining trends observed in the landings of sprat and Norway pout continued in 1989.

### 2.2 North Sea

The annual landings from the industrial fisheries for the years 1974-1989 are given in Table 2.2. For 1989, the landings have been broken down by quarters to indicate the seasonality of the various fisheries. Over the years the total landings have varied between 1 million $t$ and 1.9 million $t$; on average 1.5 million $t$. They declined from a maximum in 1974 to a minimum in 1985, rising again to 1.3 million $t$ in 1988 , and further to 1.5 million $t$ in 1989. Since 1986, sandeel landings have exceeded the exceptional high level of $800,000 \mathrm{t}$ with the 1989 figure of $1,035,000 \mathrm{t}$ being the highest on record. During this period sandeel on an average made up $70 \%$ of the total landings. The low level of sprat land-
ings was maintained in 1989. The figure of $66,000 t$ is far below the long-term mean of $245,000 \mathrm{t}$. Herring landings have fluctuated considerably without any particular trend. From a maximum of $179,000 \mathrm{t}$ in 1988, landings were reduced to $132,000 \mathrm{t}$ in 1989. The long-term decline in Norway pout landings from a maximum of $736,000 t$ in 1974 terminated with a minimum of $102,000 t$ in 1988. Though increasing to $151,000 \mathrm{t}$ in 1989, this figure is far below the long-term mean of $345,000 t$. Blue whiting landings show an irregular pattern. Landings increased from $28,000 \mathrm{t}$ in 1988 to $52,000 \mathrm{t}$ in 1989 as compared with a long-term mean of $64,000 \mathrm{t}$. By-catches of protected species decreased from 54,000 t in 1988 to 47,000 in 1989 .

### 2.3 Division VIa

The annual landings from the industrial fisheries for the years 1974-1989 are given in Table 2.3. The total landings have varied between $10,000 t$ and $53,000 t$; on an average almost $26,000 t$. No particular long-term trend is apparent, but since 1985 the total landings have been considerably higher than the long-term mean. The sandeel fishery commenced on a regular basis in 1981. Annual landings thereafter ranged from 6,000 to $24,000 \mathrm{t}$, increasing gradually up to 1986 . In the most recent years, landings have fluctuated. Landings of sprat show an irregular pattern, ranging from 850 t to $12,400 \mathrm{t}$; on an average $4,700 \mathrm{t}$. They were above the long-term mean up to 1978, remained at a comparatively stable level until 1985, and then dropped to less than 1,000 $t$ in 1986 and 1987. Following an increase to $4,200 \mathrm{t}$ in 1988, the landings again decreased to $1,100 \mathrm{t}$. Landings of Norway pout have fluctuated without any particular long-term trend, ranging from $4,900 \mathrm{t}$ to $38,300 \mathrm{t}$; on an average $12,700 \mathrm{t}$. Succeeding the maximum in 1987, landings dropped to $6,400 \mathrm{t}$ in 1988 and again increased to $28,200 t$ in 1989.

## 3 BY-CATCHES IN THE INDUSTRIAL FISHERIES IN THE NORTH SEA

The annual landings of by-catches of the major protected species in the industrial fisheries are given in Table 3.1. Total landings of haddock, whiting and saithe declined to the lowest levels recorded in 1986 and 1987 of $22,000-24,000 t$. They increased to $54,000 t$ in 1988, but slightly decreased to $48,000 t$ in 1989, of which the estimated figures were $43,000 t$ of whiting, $3,000 t$ of haddock, and $2,000 \mathrm{t}$ of saithe. In recent years the by-catch of protected species has been dominated by whiting.

Maps showing the distribution of protected species caught in the industrial fisheries were made available for 1989. They are not published in the present report, but are retained in the files of the Working Group.

The distribution of industrial landings by target species and associated by-catches are shown in Table 3.2 for the years 1988 and 1989. By-catches in the sandeel fishery were very small, amounting to $2.7 \%$ in 1988 and $1.4 \%$ in 1989. Herring by-catches were mainly associated with the sprat fishery. On an average, $88 \%$ of the herring by-catch derived from the southern North Sea (south of 57 N ). In the Norway pout fishery, which is conducted solely in the northern North Sea, by-catches mainly consisted of whiting and herring.

## 4 NORWAY POUT IN DIVISION IIIA

### 4.1 Landings

Total landings as officially reported to ICES are shown in Table 4.1. In 1989, the landings dropped to $17,000 \mathrm{t}$, less than half the value of 1988 and the lowest on record.

### 4.2 Including Norway Pout in Division IIIa in the North Sea Assessment

The Working Group was requested to consider including Norway pout from Division IIIa in the North Sea assessment. The Working Group has no objection to doing so in the future. It should be noted, however, that revising the North Sea catch at age to include Division IIIa landings for the period covered by the VPA is a major task.

## 5 NORWAY POUT IN THE NORTH SEA

### 5.1 Landings

Landings by country are shown in Table 5.1.1 for the period 19571989. Landings in 1989 were $48 \%$ greater than in 1988 and were at almost the same level as in 1987. Landings by month and country are given in Table 5.1.2 for the years 1987-1989. Landings increased in all but the first quarter of 1989 when compared with 1988.

### 5.2 Fishing Effort and Catch per Unit Effort

## Danish CPUE

Table 5.2.1 shows Danish CPUE data by vessel category for the period 1982-1989. The greatest differences between 1988 and 1989 values occur for the smallest and largest vessel categories. In 1989, there was approximately a $27 \%$ reduction in CPUE for these categories compared to 1988.

## Norweqian Effort

Number of days fished and mean GRT of the fishing vessels involved in the Norwegian directed Norway pout fishery are shown in Table 5.2.2. (The directed fishery is defined as that with more than $70 \%$ by weight of Norway pout in the catch for all years except 1988 and 1989). In 1989, effort was more than double that of the previous year, principally due to large increases in the 3 rd and 4 th quarters.

Total Danish and Norwegian Effort
Danish and Norwegian effort data were standardised to a vessel size of 200 GRT using methods outlined in the 1985 Working Group Report (Anon., 1985), except for 1988 and 1989.

The Danish CPUE and GRT data were fitted to a GLM of the form

$$
\text { CPUE }=A \text { year } \times(G R T-G O)^{b}
$$

Where $A$ year is a year-dependent coefficient, $b$ is a constant, and Go is a value selected to minimise the RMS of the model fit. Go $=50$ was selected as in previous years. However, it was felt that the coefficient b should not be forced to be a constant for all years. Hence the model as estimated in last year's report (Anon., 1989a) was applied for the period 1982-1987, and a new model was fit to data for 1988 and 1989. The results of the fit for 1988 and 1989 are given below:

$$
\begin{aligned}
& \text { CPUE }_{88}=6.017 \times(\operatorname{GRT}-50) 0.283 \\
& \operatorname{CPUE}_{89}=5.973 \times(G R T-50) 0.283
\end{aligned}
$$

The model fit for 1988 and 1989 had a coefficient of determination of 0.8 and is shown in Figure 5.2.

These results were then used to standardize effort data to a vessel category of 200 GRT, using the Danish and Norwegian catches. As the Norwegian data for 1988 and 1989 include effort directed towards blue whiting, the Norwegian catch data were used to estimate a standardized effort figure by dividing the Norwegian catch with the standardized Danish CPUE. The standardized effort data are given in Table 5.2.3.

Standardized effort in 1989 was approximately $50 \%$ greater than in 1988 and close to the 1987 level. Effort in the 1st quarter was lower in 1989 than 1988 but much greater in other quarters.

### 5.3 Catch at Age

Catch-at-age data were available from Denmark and Norway. The data were combined and raised to total international landings. Quarterly catch-at-age data are given in Table 5.3.

### 5.4 Weight at Age

Mean weight at age in the combined Danish and Norwegian catches are shown by quarter in Table 5.4.1 for the period 1986-1989.

The contribution of each age group to the total catch (by weight) is given in Table 5.4.2 for 1980-1989.

### 5.5 Research Vessel Surveys

Updated research vessel indices are given in Table 5.5. The 1group IYFS index is preliminary and based on the number of fish in the catch less than 15 cm in length. The preliminary 1 -group index for the 1989 year class from this survey is $27 \%$ lower than the previous year's index. However, the EGFS O-group index of the 1989 Year class is almost 10 times greater than previous years EGFS 0 -group index.

### 5.6 VPA

A quarterly VPA was run with terminal $F$ at age in the most recent year, estimated by quarterly tuning of the VPA using catch and
standardized effort data for 1982-1989. Terminal F at age for the oldest ages was chosen to correspond with previous years' values where quarterly VPAs had been used and a value of 0.4 was used for the quarterly natural mortality.

Input Fs for the most recent year were estimated using weighted mean log catchabilities in the fourth quarter of the year for ages 0-3 and in the first quarter of the year for age 4. Where possible, the quarter on which the catchabilities were estimated was that for which catch at age was usually the greatest. Linear downweighting of older data was applied to the log catchabilities. Catch-at-age data used in the analysis are given in Table 5.3 and the tuning statistics and resultant log catchabilities are given in Table 5.6 .1 (in this Table, predicted $F$ refers to the value of $F$ at age estimated in the tuned quarter of the most recent year, and input $F$ refers to the input value in the fourth quarter of the year that will produce the tuned value).

Estimated values of $F$ at age and number in the sea at age are given in Tables 5.6.2 and 5.6.3, respectively. Recent trends in mean $F$ at age and stock biomass totals are shown in Figures 5.6.1 and 5.6.2, respectively.

Estimated $F$ at age 2 in the fourth quarter of 1988 appears rather high, particularly in relation to input $F$ at age 2 in 1989 which is lower despite an increase in effort from 1988 to 1989. It was decided not to adjust the input value to remove this apparent anomaly, because that would also alter the catchabilities at younger ages in other years upon which the tuned input values depend. In addition, it is likely that the catch-at-age data are in error at this point due to poor sampling coverage of the Danish catches.

Mean $F$ (ages 1-2) for each quarter, 1982-1989, is plotted against standardized effort from that quarter in Figure 5.6.3, the point with the highest mean $F$ being that from the final quarter of 1988 (adj. $\mathrm{R}^{2}=0.583$ excluding the outlying point from 1988, quarter 4). VPA estimates of 1 -group numbers are ghown plotted against IYFS 1-group indices in Figure 5.6.4 (adj. $\left.R^{2}=0.539\right)$.

Trends in the stock biomass totals show the total and spawning stock biomasses to be at a low level compared to the early 1980s. This is consistent with the annual Laurec-Shepherd VPA produced in last year's report (Anon., 1989a) but not with the quarterly 'hand-tuned' results (which were only presented graphically). Since 1985, the mean spawning biomass has been approximately $200,000 \mathrm{t}$, whereas the average value for $1978-1984$ was close to 500,000 t.

### 5.7 Catch Prediction

Two catch predictions were made. One was a traditional "analytical" catch prediction and the other a SHOT prediction.

For the analytical prediction, the mean exploitation pattern, by quarter, was estimated and scaled to produce a mean $F$ (ages 1-2) equal to those calculated in the VPA for 1989. These values were used as status quo Fs at age by quarter for the prediction year. Numbers at age entered into the prediction were the arithmetic mean 0 -group numbers estimated from VPA over the period 1978-

1988; the weighted average prediction of 1 -group numbers from an updated RCRTINX2 estimate (Table 5.7.1) and VPA estimates of number at age at the start of 1990 for ages 2 and older (Table 5.6.3).

Using stock mean weights at age, the predicted catch for 1990 is 229,142 $t$ broken down by quarter as:

| QI | 13,388 |
| :--- | :--- |
| QII | 39,598 |
| QIII | 79,880 |
| QIV | 96,276 |

A SHOT prediction was performed, using recruitment at age 1 from the VPA and the RCRTINX2 estimate of the 1989 year class at age 1 (Table 5.7.1). Assuming the Y/B ratio in 1989 and 1990 to be the same as in 1985-1986, the landings in 1990 were predicted to be $187,000 \mathrm{t}$. Actual and estimated landings from the SHOT procedure are given in Table 5.7.2 and shown in Figure 5.7.

## 6 NORWAY POUT IN DIVISION VIa

### 6.1 Landings

Landings officially reported to ICES are given in Table 6.1 for the period 1974-1989. In 1989, landings rose to $28,185 \mathrm{t}$ from $6,366 \mathrm{t}$ in 1988. This is rather more than double the long-term mean, 1974-1988, of 12,700 $t$.

## 7 SANDEEL IN DIVISION IIIa

### 7.1 Landings

Estimated landings decreased somewhat in 1989 to a total of $18,170 \mathrm{t}$ (Table 7.1). The main fishing took place in the Skagerrak.

## 8 SANDEEL IN THE NORTH SEA

### 8.1 Landings in 1989

## North Sea

Landings passed over the one million level in 1989, with a total of nearly $1,035,000 t$ or a $16 \%$ increase from the landings in 1988 which were the highest on record hitherto.

Annual landings by country since the start of the fishery are given in Table 8.1.1, which shows that the increase is almost solely due to Danish landings.

Landings by month and area are further shown in Tables 8.1.28.1.4. They indicate an early start of the fisheries with maximum landings in May. In this respect 1989 resembles 1988 , and it is reasonable to assume that this is caused by the very mild winters in both 1988 and 1989.

As in 1988, areas 1 A and 2 B (Figure 8.1) were the most important, but landings from the easterly area 3 increased considerably from 1988. The Northern assessment area shows the highest landings on record while the smaller increase in the Southern assessment area did not make catches surpass the years 1978 and 1984. The Shetland landings show a further decline, principally due to a closure in the second half of the year.

### 8.2 Sandeel in the Northern North Sea

### 8.2.1 Fishing effort and CPUE

Fishing effort data were available from all fleets fishing for sandeel. The effort data for Norwegian and Danish vessels are based on logbook data with a coverage close to $100 \%$ in the most recent years.

Danish CPUE data by half of year and vessel category for 19821989 are shown in Table 8.2.1.1.

A multiplicative model was fitted to the Danish data:

$$
\text { CPUE }(\text { year, } G R T)=A(\text { year }) * G R T^{B}
$$

The model explained $91 \%$ of the variation. CPUE against GRT is plotted in Figure 8.2.1.

Danish CPUE standardized to a 200 GRT vessel in the first and second half of 1988 and 1989 is shown in Table 8.2.1.3.

Fishing days and mean GRT for the Norwegian fleet were available for the years 1976-1989 (Table 8.2.1.2).

The number of fishing days were standardized to a vessel size of 200 GRT and the corresponding CPUE was calculated. The standardized international CPUE was then calculated as an average of Danish and Norwegian data weighted by catch. Finally, standardized international effort was estimated as catch divided by CPUE. The results are shown in Table 8.2.1.3

Compared to 1988, fishing effort increased by $37 \%$ in the first half of 1989 and decreased by $15 \%$ in the second half.

### 8.2.2 Catch at age

Data on age composition were supplied by Norway for the whole fishing season, while Denmark only covered the first half of the year. For that period, Danish and Norwegian data were combined, while Norwegian data were applied to landings after 1 July. Scottish boats only fished in the northern assessment area in the first half of the year and the same was assumed for the faroese vessels. In both cases, the combined Danish/Norwegian data were applied. Quarterly catch-at-age data are given in Table 8.2.2.1 and semi-annual data in Table 8.2.2.2. In 1989, the number of 1groups caught appears to be one of the highest on record. The 1986 year class is still well represented in the catch.

### 8.2.3 Weight at age

During the first half year, combined Danish/Norwegian data were used to estimate mean weight at age in the catch, while in the second half only the Norwegian data were available. The mean weight at age in the catch is shown in Table 8.2.3.1. The mean weight at age in the stock is given in Table 8.2.3.2.

## 8.2 .4 VPA

A semi-annual VPA was performed using rates of natural mortality taken from last year's report (Table 8.2.4.1).

Because most of the landings were made in the first half of the year, terminal $F$ at age in the most recent year was estimated by tuning the VPA to data from the first half of the year. The weighted mean log catchabilities were used to predict $F$ in the most recent year. Age group 4 was chosen as plus-group and input fishing mortality for age group 3 for 1976-1988 was taken from last year's report.

For age group 2, the estimated fishing mortality for the first half of 1989 of 2.3 implied a number of fish in the sea in the second half of 1989 less than the actual catch. As a fishing mortality of 2.3 seems unrealistically high compared to recent years, the input $F$ was reduced. A value of 1.8 , the same as for age group 3, was adopted.

The input Fs for the oldest age in 1986 and 1987 were modified so that mean Fs in 1985 and 1986 corresponded to changes in fishing effort. The resulting mean Fs for 1985 and 1986 still do not reflect the change in effort, but at least they are less conflicting than the values used last year.

Finally, the O-group $F$ in 1989 was chosen to produce the mean recruitment for the period 1979-1988.

Fishing mortality and stock in numbers are given in Tables 8.2.4.2 and 8.2.4.3. Log catchabilities and tuning statistics are shown in Table 8.2.4.4.

Average $F$ over ages 1 and 2 is plotted against effort in Figure 8.2.4.1 and CPUE against biomass in Figure 8.2.4.2.

The graph of $F$ against effort produces a scattered plot, whilst there is a better correlation between CPUE and biomass.

Due to the poor 1987 year class, the spawning stock biomass has decreased from $682,000 \mathrm{t}$ in 1988 to $161,000 \mathrm{t}$ in 1989.

No predictions were made due to the lack of information on recruitment.

### 8.2.5 Effects of catches of 0 -group sandeel upon the sandeel stock in the northern North Sea

At last year's meeting, the Working Group was asked to consider the effects of catches of O-group sandeel in the North Sea. This year a working document by Lahn-Johannesen et al.
expanded these considerations further.
With respect to the $Y / R$, the conclusions reached at last year's meeting were confirmed. Implementing either a 10 cm minimum landing size or a total closure of the fishery in the second half of the year will produce only marginal changes in $Y / R$. This conclusion is, however, heavily dependent on the assumed weight-at-age and natural mortality of the 0-groups.

In terms of the SSB/R, both measures will lead to an increase. It is, however, difficult to determine a 'safe' level of SSB/R for sandeel. At present there is no evidence to suggest that recruitment is dependent upon SSB within the region of historical experience, i.e., at a SSB above $100,000 \mathrm{t}$. It is furthermore uncertain to what extent recruitment in the northern North Sea depends upon transport of larvae into this area from the southern North Sea.

If needed, the most effective way of increasing the SSB/R is to decrease the fishing mortality on the juveniles. To achieve this a closure of the fishery in the second half of the year seems to be preferable to a minimum landings size accompanied by a bycatch rule. A closure is easier to control and would provide a better protection of the 0 -groups. The reason is that in this case by-catch rules tend to work in a counterintuitive way. If recruitment is high they are difficult to adhere to (and less necessary); if recruitment is low they are not able to decrease the fishing mortality sufficiently.

### 8.3 Sandeel in the Southern North Sea

### 8.3.1 Fishing effort and CPUE

Only Danish CPUE data were available. Semi-annual data by vessel category are shown in Table 8.3.1.1.

The same model for the relation between CPUE and GRT in 1988 and 1989 was used as for the Northern North sea was used. CPUE against GRT was plotted in Figure 8.3.1. The model explained 81\% of the variation.

Effort and CPUE standardized to a vessel size of 200 GRT are given in Table 8.3.1.2. Total international effort for the first half year increased by $12 \%$ in 1989 compared to 1988 and decreased byh $56 \%$ in the second half year.

### 8.3.2 Catch at age

Catch-at-age data were provided by Denmark for the first half of the year. For the second half, the Working Group chose to apply age composition data from the first half in view of the limited landings after 1 July (about $3.5 \%$ of the total). The data are shown in Tables 8.3.2.1 and 8.3.2.2. It appears that the 1986 year class is weak in the southern assessment area as compared to the northern, while the 1985 year class is still well represented.

### 8.3.3 Weight at age

Only Danish data from the first half of the year were available and consequently used in all landings from the southern assessment area (Table 8.3.3.1). Weight at age in the stock is the same as used in last year's report (Table 8.3.3.2).

### 8.3.4 VPA

Natural mortality rate shown in Table 8.2.4.1 is the same as used in last year's VPA.

Terminal Fs for the oldest single age group were taken from last year's report. Because landings were made predominantly in the first half of the year, terminal Fs at ages 1-4 for the most recent year were estimated using catch and effort data taken from the first half of the year. Linearly-downweighted mean log catchabilities were used to estimate input $F$.

Fishing mortality for the O-group in 1989 was chosen to produce a year-class strength equal to the mean recruitment for the years 1979-1988.

The estimated $F$ for age group 2 in the first half of 1989 (Table 8.3.4.1) seems to be very low compared to the value in 1988 in spite of a corresponding increase in effort of $12 \%$. However, values of $F$ and effort in 1989 are consistent with those of 1986 and 1987, suggesting the 1988 value to be anomalous.

The spawning stock biomass (Table 8.3.4.2) has decreased from approximately 2 million $t$ in 1987 to 1.2 million $t$ in 1988 and further to 0.5 million $t$ in 1989. This change can be attributed to a strong 1985 year class, followed by two poor year classes. According to the VPA, the 1988 year class is strong and will increase the spawning stock biomass again in 1990.

Average $F$ over ages 1 and 2 is plotted against effort in Figure 8.3.4.1 and CPUE against biomass in Figure 8.3.4.2. Tuning output is shown in Table 8.3.4.3.

### 8.4 Sandeel in the Shetland Area

### 8.4.1 Fishing effort and CPUE

Fishing effort data are given in Table 8.4.1.1 for the Shetland area during the period 1977-1989. No effort took place in the 2nd half of 1989 due to the closure of the fishery within the 6 miles UK limit.

For the first time, effort data were standardized for this fishery using UK (Scotland) data. A similar GLM as used for sandeel in the southern and northern North Sea was fitted to Scottish CPUE and GRT data (using exact GRTs rather than vessel categories) with the addition of a weighting variate (days absent) applied to the catch and effort data. This gave a coefficient of determination of $82 \%$.

Standardized effort data for the period 1982-1989 are given in Table 8.4.1.2 for a vessel size of 40 GRT . Standardized effort in
the 1 st half of 1989 is $28 \%$ lower than the corresponding period in 1988. Annual standardized effort in 1989 was $47 \%$ less than in 1988 and is the lowest of the standardized series.

### 8.4.2 Catch at age

Catch at age in the Shetland fishery (millions) is given in Table 8.4 .2 by month and age group. Catches were only taken in the 1 st half of the year. O-group fish are represented in the catch quite early in the year suggesting an earlier than normal time of recruitment. 1 -group and 2 -group fish are poorly represented in the catch. Poor 2-group catches may further suggest that the 1987 year class was very poor. However, it is likely, from the spatial distribution of the fishery, that catches were taken mainly from grounds were older fish predominate. In this case a change in exploitation pattern is suggested, further compounded by the closure of the fishery prior to the period in which catches of 0 group are usually greatest.

### 8.4.3 Weight at age

Mean weight at age in the Shetland catch is given in Table 8.4.3.1 for 1989. Stock mean weights at age used to calculate biomass totals for this area are given in Table 8.4.3.2.

### 8.4.4 YPA

A semi-anual VPA was performed with input fishing mortalities in the most recent year estimated by the semi-annual tuning program available to the Working Group. Natural mortality rates and the proportions mature at age were the same as those used in last year's report (Anon., 1989a).

Input $F$ at the oldest age in all years but the most recent was chosen in accordance with previous Working Group reports. Whilst it is recognized that the chosen values are high, it should be pointed out that selecting values which are averages of $F$ over a chosen age range results in estimates of numbers at age and stock biomass totals which are greatly in excess of previous Working Group estimates. Therefore, the current values were selected for consistency with previous reports rather than introducing lower estimates (at least until further information is available).

In the shetland fishery, the bulk of the catch of 1 -group and older fish has usually been taken in the first half of the year. For that reason it was decided to tune the VPA to catch and effort in the first half of the year for those ages. No O-group $F$ at age was, therefore, estimated for 1989 due to the closure of the Shetland fishery in the second half of the year.

Standardized effort data for the period 1982-1989 were used in the tuning procedure where the mean of the $\log$ catchabilities at age was used to estimate $F$ in the most recent years. Mean log catchability was estimated as a weighted value with linear down weighting of older values. Input catch-at-age data are shown in Table 8.4.4.1, and log catchabilities at age and the tuning statistics are shown in Table 8.4.4.2.

Estimated fishing mortalities at age are given Table 8.4.4.3, and values averaged over ages 1 to 3 are shown in Figure 8.4.4.1. The estimated number of fish in the sea and stock biomass totals ( $t$ ) are given in Table 8.4.4.4. The number of O-group recruits (as of 1 July) are given in Figure 8.4.4.2, and historical biomass totals are shown in Figure 8.4.4.3. Mean Fover ages 1 to 3 is plotted against standardized effort in Figure 8.4.4.4 (adj. $\mathrm{R}^{2}=$ 0.851).

Recruitment in 1986 appears considerably stronger than previously estimated with increases in total and spawning biomass totals one and two years later. However, estimated recruitment in 1987 and 1988 is extremely low leading to subsequent declines in the stock biomass totals. Additionally, $F$ at age 0 in the second half of 1988 is estimated to be the highest on record at that age. However, it is necessary to be particularly cautious when interpreting the most recent estimates from VPA in this stock. This is because both the input and recent values of $F$ at age in the younger ages of this stock are generally very low, suggesting very slow convergence of the VPA with most estimates driven by the input values of natural mortality rate. Furthermore, it is likely that the assumption of a constant exploitation pattern has been broken in the most recent years (see Section 8.4.2), casting doubt on the validity of the tuning procedure as used here.

## 9 SANDEEL IN DIVISION VIA

### 9.1 Landings

Official landings of sandeel in Division VIa are given in Table 9.1. Landings in 1989 were $28 \%$ lower than in 1988.

### 9.2 Fishing Effort and CPUE

Fishing effort for the period 1980-1989 is given in Table 9.2 by month and year. Effort (as days absent) was $46 \%$ lower in the first half of 1989 compared with the corresponding period of 1988 and 27\% lower in the 2nd half (38\% lower in total for 1989). Effort in 1989 was around $28 \%$ below the mean for the period 19801988.

No standardized effort data are yet available for this stock.

### 9.3 Catch at Age

Catch at age by month is giuven for 1989 in Table 9.3.

### 9.4 Weight at Age

Mean weight at age for the Division VIa catch in 1989 is given by month in Table 9.4.1. Mean weights at age used to calculate biomass totals are given in Table 9.4.2.

### 9.5 VPA

A semi-annual VPA was performed using values of natural mortality at age and proportion mature at age as given in the previous Working Group report (Anon., 1989a). The comments applied to the choice of $F$ at the oldest age for Shetland sandeel (see Section 8.4.4) also apply here. Input values of $F$ at age for the oldest ages were also as used previously. Input value of $F$ at age for the most recent years was estimated from the semi-annual tuning package using catch and effort data from 1982 to 1989, a log transformation of catchabilities, and the predicted value estimated as a weighted mean with linear down weighting of older data. For all ages, the VPA was tuned to catch and effort data in the second half of each year.

Input catch-at-age data are given in Table 9.5.1 with the tuning statistics and log catchabilities at age given in Table 9.5.2. Estimated values of $F$ at age are given in Table 9.5.3 with trends in mean $F$ (ages 1-3) shown in Figure 9.5.1. Estimated number in the sea and biomass totals (tonnes) are given in Table 9.5.4. Trends in recruitment and biomass totals are shown in figures 9.5.2 and 9.5.3, respectively. Figure 9.5.4 shows the plot of mean $F$ (ages 1-3) against effort for the years 1980-1989 (adj. $\left.\mathrm{R}^{2}=0.765\right)$.

These results suggest a considerable upward revision of the 1986 year class estimate to rather less than three times greater than any other year-class strength. This revision has obvious consequences for the subsequent estimates of stock biomass totals in the following years. The revision appears justified in view of the representation of the 1986 year class in catches from successive years. Estimates of year-class strength subsequent to the 1986 year class suggest that recruitment has been below average resulting in a decline in biomass totals in the most recent years, particularly as the influence of the 1986 year class diminishes. Biomass totals are still greater than the mean values since the start of the fishery.

## 10 SPRAT IN DIVISION IIIa

### 10.1 Landings

The landings by area and countries for the period 1978-1989 are shown in Table 10.1. These figures are based on preliminary data provided by the Working Group members. The total landings in 1989 is slightly below the number for 1988 , which was the lowest on record until then.

### 10.2 Research Vessel Surveys

Final indices for 1 -group and older sprat from the IYFS are given in Table 10.2. This year is the third in succession with very low indices for the 1 -group. The index for 2 -group and older has declined rapidly as the previous stronger year classes have disappeared, and it is now at an all time low level.

### 10.3 State of the Stock and Catch Predictions

According to the IYFS indices, the recruitment has been poor for the last 3 years, and the stock has by now reached a very low level. This is also apparent in the decline of the commercial catches in the later years.

Using the SHOT-method with the regression

$$
Y(t)=0.228 Y(t-1)+14.52 R_{1}
$$

as in previous years, gives an estimated catch in 1990 of 9,128 $t$.

These SHOT estimates have tended to be too high compared to actual landings for the past two years.

There are strong reasons to believe that the $Y / B$ ratio currently used is too high. In the 1970s and up to 1984, the industrial landings dominated. Since 1985, the balance has changed to a dominance of landings for human consumption generated by coastal purse seine fleets which are known to fish selectively for large sprat, thus generating proportionally higher $F$ values for 2 -group and older sprat compared to the earlier period.

The Group, therefore, decided to make a set of new SHOT estimates based on data from 1979 and later. The start year 1979 was chosen because the standard GOV trawl was introduced that year, and a change in catchability is expected to influence the IYFS recruitment indices of sprat.

The SHOT was run with a range of $Y / B$ ratios from the "old" 0.772 to 0.4 for all years and also with a change from 1985 and onwards. The closest fit between predicted and actual landings for the most recent years was obtained with $Y / B$ ratios of 0.772 up to 1984 and 0.6 from 1985 and later years (Figure 10.3). The predicted landings in 1990 were relatively insensitive to the $Y / B$ ratio used for 1985 onwards. Y/B ratios of 0.4 gave unrealistic low or negative production. The predicted catch in 1984 was an outlier in all runs.

The Working Group, therefore, decided to use the SHOT estimate with $Y / B$ ratios of 0.772 and 0.6 , respectively, which resulted in a predicted landing for 1990 of $7,600 \mathrm{t}$.

## 11 SPRAT IN THE NORTH SEA

### 11.1 Landings

The preliminary figure $63,300 t$ for the landings of sprat in the North sea in 1989 is somewhat lower than in 1988, but still well above the landings in previous years.

Table 11.1.1 shows the annual landings by area and country, and Table 11.1.2 shows the landings by area and quarter. The discrepancy between these two tables is due to the landings from other countries, and to the landings from the Norwegian fjords, which are only included in Table 11.1.1. As in previous years, the majority of the catch ( $94 \%$ ) was taken by Denmark in Division IVb East. As in 1988, the main fishery took place in the third
quarter, but in 1989 a substantial fishery also took place in the first quarter.

### 11.2 Catch at Age

Quarterly data for catch in numbers at age were available from Denmark, UK (England) and Norway (Table 11.2). In all seasons, the catches were dominated by 1 -group and 2 -group fish, the latter being slightly more abundant.

### 11.3 Weight at Age

Danish data for quarterly mean weight at age in the catch are shown in Table 11.3

### 11.4 Research Vessel Surveys

### 11.4.1 Acoustic surveys

Acoustic surveys were carried out by Norway in June and July 1989 covering the eastern part of the northern North Sea and by Denmark in July 1989 covering the central North Sea. Norway did a second survey covering the eastern North Sea in November-December.

These surveys are primarily designed to estimate herring abundance. The estimates for other species, including sprat, must be considered as by-products, and are mainly obtained from the species composition in the trawl hauls. The estimated biomasses are summarized below:

June - July 1989
$54-56^{0} N$ East $:$
$54-50^{0} N$ West

$56-62^{0} N$$\quad$| $6,900 t$ |
| :---: |

November - December 1989
Division IVb East : $11,000 \mathrm{t}$
These numbers are below those of 1988.
The estimated stock sizes are, however, as in previous years, far below the actual landings. As in 1988, the Working Group, therefore, decided to disregard these data in the assessment of the North Sea sprat stock

### 11.4.2 International Young Fish survey

Preliminary data from the IYFS in February 1990 (Table 11.4) in the North Sea were available to the Working Group, based on a compilation of 372 hauls in 134 statistical rectangles. As age distributions were not yet available, the distribution of sprat shown in Figure 11.4.1 comprises only sprat $<10 \mathrm{~cm}$. Taking this as mainly 1 -group, a preliminary index for Division IVb is 175. This value is comparable to that for 1986 and 1988, but far below the value for 1989.

### 11.5 Catch Predictions

Since 1986, the landings of sprat from the North sea have increased gradually from a very low level. This trend was broken in 1989. The IYFS index of 1 -year-olds in 1989 indicated an exceptionally large 1988 year class, which led to a very high catch prediction for 1989. This prediction was not fulfilled, and the contribution of this year class to the catches was smaller than that of the presumably small 1987 year class. On the other hand, there are no obvious technical reasons for rejecting the 1989 1year IYFS index, and the index for this year class as 2-year olds is not yet available. The acoustic estimates of sprat abundance have been of little use, since they tend to give unrealistically low values. Because of this, the Working Group found that the available information was insufficient to allow any assessment or catch prediction this year.

## 12 SPRAT IN DIVISION VIa

The landings of sprat from Division VIa are shown in Table 12.1. Landings this year were by the UK (Scotland) only. Of the total of $1,146 \mathrm{t}$, 16 t were taken in the first quarter, the remainder in the fourth quarter.

The catch in numbers at age and the mean weight at age are shown in Table 12.2.

## 13 SPRAT IN DIVISION VIId,e

### 13.1 Landings

The nominal landings are shown in Table 13.1.1. The total catch in 1989 of about $3,400 t$ is somewhat lower than in 1988, but higher than in 1986-1987.

The English fishery showed the following development:
As usual, marketing restrictions severely constrained fishing effort for sprat in the eastern Channel and landings were consequently small. In the western Channel, the Lyme Bay fishery (Table 13.1.2) ended the 1988/1989 season in February, and commenced the 1989/1990 season in August. The catch in 1988/1989 amounted to $2,729 \mathrm{t}$, about average for recent seasons, but the current 1989/1990 season faded out in November after a promising start to the season. The sprat shoals initially concentrated extremely close to the shoreline on the western side of the Bay during September. At one stage they entered Brixham harbour and the River Dart, which caused problems in fishing them. However, when the shoals eventually moved offshore they then dispersed and subsequently proved difficult to locate. As a result, the catch for the 1989/ 1990 season (1,097 t including January 1990) may well be the lowest recorded since the early 1970s.

### 13.2 Catch at Age

Age compositions for the seasons $1966 / 1967$ to $1989 / 1990$ for the Lyme Bay fishery are shown in Tables 13.2.1 and 13.2.2. The 1986 year class contributed about $68 \%$ to the catch early in 1989, and
still made a major contribution ( $38 \%$ ) in the latter part of the year.

### 13.3 Weights at Aqe

The mean weight at age for the Lyme Bay fishery is shown in Table 13.3. As in 1988, the mean weight at age in the dominating 1986 year class is somewhat below the long-term average.
