## REPORT OF THE

# HERRING ASSESSMENT WORKING GROUP FOR THE AREA SOUTH OF $62^{\circ} \mathrm{N}$ 

ICES Headquarters<br>10-19 March 1997

## Part 2 of 2

This report is not to be quoted without prior consultation with the General Secretary. The document is a report of an expert group under the auspices of the International Council for the Exploration of the Sea and does not necessarily represent the views of the Council.

Conseil International pour l'Exploration de la Mer

### 3.1 The Fishery

### 3.1.1 ACFM advice and management applicable to 1996 and 1997

ACFM stated again in 1996 that the state of the stock is uncertain as available information is conflicting. Results from research surveys indicate intermediate to high levels of mortality.

The management advice was, that if a precautionary TAC was required for Sub-divisions 22-24, the catch levels in that area should not exceed recent catches.

The 1996 agreed herring TAC between the EU, Norway and Sweden to be taken in Division IIIa was $120,000 \mathrm{t}$. A TAC including all catches of all species taken in the mixed clupeoid fishery and landed unsorted was set at $43,000 \mathrm{t}$.

In June 1996 the TACs for the area were changed. A $25 \%$ reduction in the directed herring fishery was agreed between EU and Norway.

As in previous years no special TAC was set by the International Baltic Sea Fishery Commission (IBSFC) for the stock component in the Western Baltic area in 1996. In the Baltic there is a TAC for all the Sub-divisions 22-32.

## Introduction to landing statistics

The landings of herring caught in Division IIIa are a mixture of North Sea autumn spawners and Baltic spring spawners. Spring-spawning herring in the eastern part of the North Sea, Skagerrak, Kattegat and Sub-Divisions 22, 23 and 24 are considered to be one stock. This section gives the landings of both North Sea autumn spawners and Baltic spring spawners, but the stock assessment applies only to the spring spawners.

### 3.1.2 Total Landings

Landings from 1985 to 1996 are given in Table 3.1.1. In 1996 the total landings decreased to around $173,000 \mathrm{t}$ in Division IIIa and Sub-Divisions 22-24, of which 44,000 t were from the Kattegat, about 71,000 t from the Skagerrak and $57,000 \mathrm{t}$ from Sub-Divisions 22-24. This represents a decrease of $58,000 \mathrm{t}$ compared to 1995 and it is the lowest level in the time series.

There are several reasons for this significant drop in total landings. First of all the $25 \%$ reduction in the TAC for human consumption fisheries in Division IIIa and a very restrictive management of the small meshed fishery in Kattegat and Skagerrak. The herring fishing fleet in Sub-divisions. 22-24 changed to fishing for cod and for sprat in the eastern Baltic area.

Misreporting of fishing grounds still occurs. Some of the Danish landings of herring for human consumption reported in Division IIIa may have been taken in the adjacent waters of the North Sea in quarters 1, 2 and 4. These landings are included in the figures for the North Sea.

A substiantial part of Swedish landings has been misreported to be caught in the triangle (an area in southern Kattegat which is a part of the Baltic area, Gilleleje, DK - Kullen, S - Helsingborg, S - Helsingør, DK) were included in the figures for Kattegat and Skagerrak.

No estimates of discards were available to the Working Group. In Denmark a program for monitoring discards in different fisheries is conducted. This program has only been running for one year. The preliminary data show that the amount of discards is negligible or none at all in the herring and sprat fisheries in Kattegat and Sub-Divisions 22 24. The magnitude of discarding in Skagerrak may be at a high level, especially in the summer period where there is a special demand for high quality herring to the Dutch market.

The herring catches in Division IIIa are taken mainly in three types of fisheries (see Section 2.15).:

- A directed fishery for herring (fleet C) in which trawlers (with 32 mm mesh size) and purse seiners participate.
- The "Mixed clupeoid fishery" (fleet D) is carried out under a special "Sprat" TAC for all species caught in this fishery.Danish boats have been obliged to use a 32 mm mesh (since 1 Jan 1991). The Swedish fishery by purse seiners fishing for sprat along the coast. Norwegian purse seine catches of sprat for the canning industry.
- Catches of herring also occur as by-catches in small meshed fisheries (fleet $\mathbf{E}$ ) (mesh size<32 mm), such as the Norway pout, blue whiting and sandeel fisheries.

Attempts have been made to separate the landings of these fisheries. The category "Mixed clupeoids" only refers to Denmark since it was not possible to separate the Norwegian and Swedish "Mixed" landings from other industrial landings. During the WG meeting is was not possible to separate Norwegian and Swedish herring by-catch landings from trawl fisheries with a mesh size less than 32 mm , therefore, Fleet E landings only refer to Denmark. All Swedish herring landings fished by vessels using 32 mm mesh size are counted under Fleet C. Norwegian herring by-catches from the small meshed fishery are negligible. These landings are counted under Fleet C.

The landings in the different fisheries for the period 1991-1996 in thousands of tonnes are shown in Table 3.1.2. It should be noted, that the fleet definition has been changed and therefore landings by fleet for 1995 are changed and the new fleet definition was used for 1996 (see Section 2.15).

In Sub-Divisions 22-24 most of the catches are taken in a directed fishery for herring and some as by-catch in a directed sprat fishery. All catches from Sub-Div. 22-24 are treated in this section as one fleet.

The landings from this stock could therefore be split into four fleets:
C: Fleet using 32 mm mesh size in Division IIIa.
D: Mixed clupeoid fleet in Division IIIa.
E: Fleet using mesh size less than 32 mm Division IIIa.
F: Landings from Sub-Divisions 22-24.
In the text table below the 1996 landings are given in thousands of tonnes by fleet and quarter.

| Quarter/ | Fleet C | Fleet D | Fleet E | Fleet F | Total |
| :--- | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{1}$ | 13.9 | 6.9 | 5.2 | 9.3 | 35.3 |
| $\mathbf{2}$ | 12.5 | 0.0 | 2.2 | 23.9 | 38.6 |
| $\mathbf{3}$ | 46.2 | 1.0 | 2.2 | 10.1 | 39.5 |
| $\mathbf{4}$ | 19.4 | 5.9 | 2.4 | 13.5 | 41.2 |
| Total | 92.0 | 13.8 | 10.1 | 56.8 | 174.6 |

The landings from fleets C-F are SOP figures.

### 3.2 Stock Composition

### 3.2.1 Spring spawners in the North Sea

### 3.2.2 The mixing of spring and autumn spawners in Division IIIa

Catches of herring in the Kattegat and Skagerrak are taken from a mixture of two main spawning stocks (ICES 1991/Assess: 15): the Baltic spring spawners and the North Sea autumn spawners.

In addition several local stocks have been identified (Jensen, 1957). These are however considered to be less abundant and therefore of minor importance to the herring fisheries (ICES 1991/Assess: 15).

The North Sea autumn spawners (NSAS) enter Skagerrak and Kattegat as larvae and migrate back to the North Sea at an age of 2-3 years (Rosenberg \& Palmén, 1982). The Baltic spring spawners (BSS) spawn around the Baltic island Rügen. They enter the Belt Sea, Kattegat and Skagerrack as adults after spawning (Biester, 1979).

The herring stocks in the Kattegat and the Skagerrak have traditionally been separated by the average counts in number of vertebrae in herring samples (Rosenberg \& Palmén, 1982; Gröger \& Gröhsler, 1995 and 1996). NSAS have a mean number of 56.5 vertebrae while the BSS are represented by a lower mean number, 55.8 vertebrae. The
most prominent local spring spawning herring, the Skagerrak spring spawners (SSS), are represented by a higher mean number, 57.0 vertebrae.

Following the tradition from Heinke (1898) several other morphometric and metric variables have been used to separate herring stocks (Rosenberg \& Palmén, 1982). The use of most of these variables was evaluated by an ICES study group in 1992 (Anon., 1992). The group concluded that a simple modal length analysis of the relevant 1-2 age groups would be precise enough for routine assessment purposes.

However, modal length analysis has proved to be an imprecise measure requiring a large sampling effort. Experience within the Herring assement working group showed that the separation procedure often failed. The amounts of herring catches that were allocated to the NSAS stock have varied between 30 to $50 \%$ of total annual landings during the last 10 years. Errors in the estimate of this withdrawal will clearly affect the quality of the assessment of the BSS stock. A more precise measure is needed.

The diameter of the first winter ring (annuli) on the otoliths of autumn spawners are significantly larger than for spring spawners (Rosenberg \& Palmén, 1982). The analysis of otolith annuli has however not been applied on a routine basis in the Kattegat -Skagerrak area, because it is more labour-demanding. New image analysis systems can however remove this obstacle.

Otolith microstructurial otolith analysis has also been tested to separate spring and autumn spawned larvae (Moksness \& Fossum, 1991) and adults (Zhang \& Moksness, 1993). Otolith growth, which can be inferred from microscopical examination, is significantly slower for autumn spawners. Mosegaard \& Popp-Madsen (1996) showed that the processing speed of the method can be accelerated by image analysis and training. The disadvantage of a lower number of measurements is outweighted by a very high precision. Efficient grinding methods opens up the possibility to include ages more than 2 years old in a routine examination.

### 3.2.3 Treatment of autumn spawning herring in Division IIIa

For 1996 a new method was employed using otolith micro-structure for separating Baltic spring spawners from North Sea autumn spawners (Mosegaard \& Popp-Madsen, 1996).

The method allows the stocks to be separated at the individual level for all age classes and will produce proportions directly from the samples taken. Double checking of readings gives an estimated error rate of less than $1 \%$ when separating autumn/winter from spring spawners (including possible local populations with similar characteristics) (Mosegaard, W.D.).

For the third and fourth quarters otolith analyses of samples from the Danish surveys were used to calculate proportions of spring spawners by ICES rectangle within Div. IIIa.

For the first quarter herring vertebral counts from the Swedish surveys were applied in the same manner as in previous years, were the fraction of spring spawners by ICES rectangle within Div. IIIa, was calculated as follows:

$$
\mathrm{f}(\mathrm{sp})=[\mathrm{vs}(\mathrm{au})-55.8] /[56.5-55.8]
$$

where vs(au) was the sample mean vertebral count (ICES 1992/H:5). The mean proportion of spring spawners for each of the age classes $0,1,2,3$, and $4+$ within each of the Sub-divisions, Skagerrack and Kattegat, was calculated as the average of the individual proportions over the respective ICES rectangles.

For the second quarter the proportion for each Sub-division was calculated as the average of quarter one and quarter three for each of the age classes 1 to $4+$.

The resulting split is summarised below as autumn spawners and spring spawners by age in each quarter:

| Quarter | Winter <br> rings | Skagerrak |  | Kattegat |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Spring <br> Spawners | Autumn <br> Spawners | Spring <br> Spawners |  |
|  | 0 |  |  |  |  |
|  | 1 | 0,84 | 0,16 | 0,88 | 0,12 |
|  | 2 | 0,69 | 0,31 | 0,3 | 0,7 |
|  | 3 | 0,57 | 0,43 | 0,46 | 0,54 |
|  | $4+$ | 0 | 1 | 0 | 1 |
| 2 | 0 |  |  |  |  |
|  | 1 | 0,87 | 0,13 | 0,67 | 0,33 |
|  | 2 | 0,45 | 0,55 | 0,19 | 0,81 |
|  | 3 | 0,35 | 0,65 | 0,35 | 0,65 |
|  | $4+$ | 0 | 1 | 0 | 1 |
| 3 | 0 | 0,65 | 0,35 | 0,83 | 0,17 |
|  | 1 | 0,90 | 0,1 | 0,46 | 0,54 |
|  | 2 | 0,21 | 0,79 | 0,17 | 0,83 |
|  | 3 | 0,14 | 0,86 | 0,24 | 0,76 |
|  | $4+$ | 0 | 1 | 0 | 1 |
| 4 | 0 | 1 | 0 | 1 | 0 |
|  | 1 | 0,85 | 0,15 | 0,45 | 0,55 |
|  | 2 | 0,01 | 0,99 | 0,17 | 0,83 |
|  | 3 | 0,07 | 0,93 | 0 | 1 |
|  | $4+$ | 0 | 1 | 0 | 1 |

All landings from Sub-divisions 22-24 are assumed to be Baltic spring spawners.

### 3.2.4 Estimation of precision in the historical proportion of spring spawners

Earlier estimates of proportion of spring spawners have been based on a combination of a modal splitting of length frequencies confirmed by vertebral counts on resulting length groups (ICES 1992/H:5). The splitting procedure is sensitive to weightings of sampling strata and the initial choice of means and standard deviations, several solutions therefore lead to a high degree of subjectivity. Historically it has been impossible to apply the method when more than two modal groups have emerged. In an exercise the method could not reproduce earlier splitting factors for Kattegat and Skagerrak (Figure 3.2.4.1 and Figures 3.2.4.2 a\&b).

The combined data base of Swedish and Danish vertebral counts from 1991 to 1997 and 1984 to 1995 respectively, was used to study variability within Sub-divisions (Kattegat and Skagerrak) by year, quarter, age group, and ICES rectangle. Standard deviation was plotted against mean vertebral count and compared to a simulated pattern ( $\mathrm{n}=1000$ runs) from samples of two mixed stocks with mean $\mathrm{vs}=55.8$ and 56.5 respectively and a common $\operatorname{sd}=0.7$, the samples were taken from a similar pattern in sample sizes. A very similar pattern between observed and simulated data suggested that the mix in Division IIIa may very well be composed mainly of the two traditionally expected stocks, North Sea autumn spawners and Baltic spring spawners.

The proportion of spring spawner 2-ringers calculated by vertebral counts was compared to the HAWG's earlier estimated proportions by Sub-division, year, and quarter (Figs. 3.2.4.2a and 3.2.4.2b ). The results show substantial deviation between the two estimates as well as a large variation within and among years.

It was therefore concluded that the simulated pattern of symmetrical $95 \%$ confidence limits for different median vertebral counts and sample sizes could be used as a measure of the minimum variation in proportion of spring spawners in earlier years of HAWG estimates (see Figure 3.2.4.3).

### 3.2.5 Estimation of the precition in the split for 1996

The precision using the analysis of otolith microstructure may be calculated from the binomial distribution and depends almost entirely on the observed proportion and the sample size. Analysis of the variation shows a dominating and significant component of between squares variation, therefore the estimated proportion will largely be influenced by sampling stratified by square, age class, and quarter. This consideration may also apply to the method of vertebral counts.

Danish and Swedish samples from 1996 surveys taken during the third quarter were compared by age and ICES rectangle. The difference in the estimated proportion of spring spawners between otolith determined Danish samples and Swedish samples determined by vs-count, were:

$$
2.9 \% \text { (mean) }+/-30.6 \% \text { (sd) }(\mathrm{n}=27 \text { samples) }
$$

The greater than $30 \%$ in standard deviation is primarily determined by variability in the proportion of BSS determined by vs-counts. Thereby this figure is highly influenced by the low number of herring in some of the age groups from some of the squares.

### 3.2.6 Estimation of bias in the proportion of spring spawners in the catch

Besides the variation in the estimated proportion of spring spawners due to an overlap in meristic characters, a possible bias may exist when estimating the split in the landings from stock identification of different age classes in the surveys. When plotting vertebral counts in herring from surveys versus the same character from the fisheries by Sub-division, year, quarter, and age class, a bias is noted towards a higher mean vs in herring sampled from the landings. This means that more North Sea herring are taken by the fisheries than is representative for Div. IIIa (Figure 3.2.5). The estimated proportion of autumn spawners in the fisheries was overall $\mathbf{1 4 . 6 \%}$ higher than in surveys and the difference was statistically significant ( $2 *$ S.E. $=10.9 \%$ ). The problem is obviously greatest for 2-ringers where the difference was $\mathbf{3 1 . 3 \%}(2 *$ S.E. $=20.7 \%)$.

### 3.3 Catch in numbers and mean weights at age

The sampling intensity of the landings in 1996 was at a higher level than in 1995. The Swedish catches from Skagerrak for industrial purposes were sampled in the last three quarters (see Table 3.4.1). The sampling of the human consumption landings were generally acceptable in Skagerrak and Kattegat. Since, the Danish and Swedish sampling intensity in Sub-Division 24 was at a very low level, German samples from the fourth quarter were used to estimate catch in numbers for the third and fourth quarter. The Danish sampling intensity in Sub-Division 22 was at an adequate level for quarter 1 and 2. A few Swedish and Danish commercial samples were taken from Sub-Division 23 , the Sound. Samples from Sub-Division 24 were used to calculate catch in numbers and mean weights in this area. The Polish and German landings were sampled in the most important quarters.

Based on these data the total numbers and mean weights at age for herring landed from the Kattegat, Skagerrak and Sub-Division 22-24 by the fleets listed in Section 3.1.3. were compiled and shown in Tables 3.3.1-3.3.7.

Based on the above proportions, the catches in number and mean weights by age group for spring- and autumnspawning herring in each of the three fisheries in Division IIIa, are given in Tables 3.3.3-3.3.6 The landings of spring spawners taken in Division IIIa and the North Sea in 1996 were thus estimated to be about 74,000 t (Table 3.3.11) compared to about $96,000 \mathrm{t}$ in 1995, $97,000 \mathrm{t}$ in 1994 and $89,000 \mathrm{t}$ in 1993. This reduction in landings is due to the reduction in the TAC for 1996 compared with previous years. The total catch in numbers of BSS in Division IIIa and the North Sea is shown in Table 3.3.8.

The landings of North Sea autumn spawners in Division IIIa amounted to 42,000 tons compared to 70,000 tons in 1995 and to $86,000 \mathrm{t}$ in 1994 (Tables 3.3.9). The 1994-1996 landings represents a significant reduction compared to 1992 and 1993 when $152,000 \mathrm{t}$ and $132,000 \mathrm{t}$ were taken.

The total catch in number and mean weight at age of Division IIIa/Baltic spring spawners in the North Sea, Division IIII and in Sub-Divisions 22-24 for 1987-1996 are given in Tables 3.3.10 and 3.3.11.

Table 3.3.7 gives the total landings in numbers and mean weight at age by fleet of the Division IIIa/Baltic springspawning herring caught in the North Sea, Division IIIa and in Sub-Divisions 22-24 in 1996. The total landings in

1996 were $130,000 \mathrm{t}$ compared with 1995 where total catch were $173,000 \mathrm{t}$ and in $1994164,000 \mathrm{t}$. This reduction is probably due to a reduction in the TAC's for Division IIIa and in the North Sea for 1996.

Even though, the fleet definition for 1995 was changed, catch in numbers and mean weight for the WB spring spawners in Division IIIa and in Sub-Divisions 22-24 was not changed.

### 3.4 Quality of catch and biological sampling data

The data on landings have been improved since 1993 and 1994 but is at the same level as in 1995. Danish landings were sampled in all quarters for Skagerrak, Kattegat and in quarter 1 and 2 for Sub-Division 22. No samples were taken from the Sound (Sub-Division 23) and Sub-Division 24. Swedish landings from the human consumption fishery were sampled in all quarters and landings for industrial purposes from Skagerrak and Kattegat have been sampled at highest level ever. From the Norwegian landings from Skagerrak only 2 samples were taken.

Table 3.4.1 shows the number of fish aged by country, area, fishery and quarter. The total landings from Division IIIa, IIIb and IIIc were, $173,000 \mathrm{t}$, from which 390 samples were taken. A total of 64,000 herring were measured and 15,500 aged. The figures for 1996 are nearly at the same level as in 1995 . The sampling intensity by quarter over all landings are acceptable, with a mean of more than one sample per 1000 t landed. The distribution over seasons, areas and fishing fleets needs to be improved.

Sampling of the Danish catches for industrial purposes was at a much higher level than in previous years and are now at an acceptable level. The number of samples and number of fish investigated were considered to be at a reasonable level. Again in 1996 there have been difficulties in getting samples from the Danish directed herring human consumption fishery in Skagerrak.

There is uncertainty about where the Danish catches for human consumption, reported from Division IIIa (quarters 1, 2 and 4), were actually taken. These landings were most likely to have been taken in the North Sea and were therefore transferred to the North Sea.

In 1996 Sweden established a new sampling programme for the industrial landings from Division IIIa. This sampling programme met the requirement of the agreed level of one sample per 1000 t landed. Swedish sampling in Kattegat was adequate but sampling of landings by Swedish vessels in Denmark still needs to be improved (see section 2.15).

The Norwegian and Danish fishery for human consumption takes place in the area around the border line between the North Sea and Skagerrak and misreportings are known to occur.

Due to market conditions, technical regulations and quotas, discarding occurs in the purse seine fleets and in some fleets in the trawl fishery in Division IIIa, especially in June, July and August. Lack of sampling of discards creates problems which need to be resolved for the assessment.

Although the overall sampling meets the recommended level of one sample per 1000 t landed per quarter the coverage of different fisheries, areas and seasons are not adequate.

For reasons discussed in section 2.15 the Working Group recommends that adequate sampling is conducted for all fisheries in Division IIIa and Sub-divisions 22-24.

Each nation should provide information on the level of sampling to determine species composition in all fisheries in which herring are caught.

### 3.5 Fishery-independent estimates

### 3.5.1 German bottom trawl surveys in Sub-divisions 22 and 24

The German bottom trawl surveys have been conducted in Sub-divisions 22 and 24 since 1978 by the Institute for Hochseefischerei. Since 1992 the surveys are carried out by the Institute for Baltic Fisheries in Rostock. Depending on the availability of research vessel they were conducted either in November/December or in January/February. The main purpose for these surveys has been to estimate recruitment indices for cod stocks. The survey stations were randomly selected in the first year. After the first year a fixed station grid was used. Sub-division 22 is only covering the Mecklenburger Bucht (20 stations), which is taken as one depth stratum.

Sub-division 24 is divided into four depth strata ( 31 stations). Trawling is done by the herring bottom trawl 'HG $20 / 25^{\prime}$. From each station the catch in number at age is estimated (cod, herring, sprat and flounder). In Subdivision 22 the arithmetic mean values at age are used as indices. The calculated indices at age in Sub-division 24 are stratified means weighted by the area of the depth strata.

Details of the survey design and the gear (HG 20/25) as well as some results for the period 1978 to 1985 are given in Schulz and Vaske (1988).

Abundance indices for $0,1,2$, and $3+$ ringed herring from bottom-trawl surveys carried out in November/December of each year in Sub-divisions 24 and 22 are given in Tables 3.5.1 and 3.5.2. Combined estimates for the total area are obtained by weighting the single survey estimate by the survey areas of each Subdivision. The resulting index series is shown in Table 3.5.3.

The 1996 survey shows in both areas relatively low 1996, 1995 and 1994 year classes. In Sub-division 22 the 0group herring in 1996 is the lowest recorded since 1979. As earlier years the 3+ group in Sub-division 24 seems to be rather high.

Abundance indices for 1 to $8+$ ringed herring from bottom-trawl surveys conducted in January/February each year in Sub-division 24 are given in Table 3.5.4. Since the 1987 survey was influenced by a strong winter with a high ice coverage the estimated abundance indices should be used with caution. Compared to the estimates for the period 1979 to about 1990 there is in the last years a general trend with lower indices for 1, 2 and 3 -ringers and higher estimates for the 6,7 and $8+$-ringers, respectively.

### 3.5.2 Summer Acoustic survey in Division IIIa

This survey is part of an annual survey covering the North Sea and Division IIIa in July-August. As in previous years the survey was conducted by R/V DANA. The echo integration survey from 19 to 30 July covered the North Sea east of $5^{\circ} \mathrm{E}$ between $57^{\circ} \mathrm{N}$ and $59^{\circ} \mathrm{N}$, the Skagerrak and the Kattegat. Acoustic data were collected using a Simrad EK400 38 kHz Simrad echosounder with a hull mounted split-beam transducer (type ES 38-29). The echointegration data were stored by the echo analysis system ECHOANN (Degnbol et al., 1990).

Pelagic trawling was carried out using a Fotö trawl ( 16 mm in the codend), while an Expo trawl ( 16 mm codend) was used on the bottom. The trawl hauls were performed in the time intervals $12.00-18.00 \mathrm{~h}$ and $23.00-5.00 \mathrm{~h}$. The TS relationships used in this survey were:
$\begin{array}{ll}\text { Clupeids: } & \text { TS }=20 \log \mathrm{~L}(\mathrm{~cm})-71.2 \\ \text { Gadoids: } & \mathrm{TS}=20 \log \mathrm{~L}(\mathrm{~cm})-67.5\end{array}$
A total of 36 trawl hauls were carried out. Further details of the survey are given in Simmonds et al. (W.D.1997).
The total stock sizes of Western Baltic spring spawning herring in the years 1992 to 1996 were estimated by combining the results from the Danish (Division IIIa) and Norwegian Acoustic Survey (Sub-area IVa and IVb). The result are summarized in Tables 3.5.5-3.5.9. The total stock estimate for $1996(215,100 \mathrm{t})$ is about $58 \%$ lower than the estimate for $1995(506,200 \mathrm{t})$. During the hours of darkness herring rise close to the surface in Skagerrak and Kattegat, and may not be registered by the hull mounted transducer. Normally a towed-body transducer, which can be deployed close to the surface, is used for echointegration during the Danish surveys. However, in 1996 the towed-body was out of action which could explain the large decrease in biomass observed between 1995 and 1996.

### 3.5.3 October Acoustic survey in Western Baltic and the Southern Part of Division IIIa (Kattegat)

The cruise carried out with R/V 'Solea' from 2 to 18 October 1996 represents the 9th subsequent joint hydroacoustic survey between the Germany and Denmark since 1987. The survey covered the whole of Subdivisions 22, 23, 24 and the southern part of the Kattegat. The acoustic equipment used was an echosounder EK500 connected to the Bergen-Integrator BI500. The transducer ES 38-26 was installed in a towed body.

Pelagic trawling was carried out using a 'PSN 480' trawl, while an 'Aalhopser' trawl was used near the bottom. All investigations were performed at night (18.00-06.00 h) as in recent years.

The $s_{a}$ values for each stratum were converted into fish numbers using the TS-length relationships:
$\begin{array}{ll}\text { Clupeids: } & \mathrm{TS}=20 \log \mathrm{~L}(\mathrm{~cm})-71.2 \\ \text { Gadoids: } & \mathrm{TS}=20 \log \mathrm{~L}(\mathrm{~cm})-67.5\end{array}$

The total number of fish was divided into species and age groups according to the trawl results. A total of 52 trawl hauls were made for biological samples.

The survey results in the years 1992 to 1996 are given in Tables 3.5.5-3.5.9. The total estimated stock size of spring spawning herring in Sub-divisions 22-24 in 1996 ( 229,200 t) was about the same level as in 1995 (244,200 t).

### 3.5.4 Acoustic Monitoring in Sub-Division 23 (the Sound)

A base-line study on the migration of herring was initiated in the autumn of 1993. The main purpose of this study is to provide information for the evaluation of possible environmental impacts of the construction of the Sound Bridge between Denmark and Sweden. A description of the survey and the corresponding results concerning the numbers and the biomass in tonnes during the period September 1993 to May 1995 are given in last years Working Group Report (ICES 1996/Assess:10). The estimates for 1996 cannot be presented because they were not available during the meeting.

### 3.5.5 Larvae surveys

The German herring larvae monitoring started in 1977 and takes place every year from March/April to June in the main spawning grounds of the spring spawning herring in the Western Baltic in the Greifswalder Bodden (area: $510.2 \mathrm{~km}^{2}$, volume: $2,960 \times 10^{6} \mathrm{~m}^{3}$, mean depth: 5.8 m , greatest depth: 13.5 m ) and adjacent waters. Since 1977 the same sampling method, sampling strategy and station grid have been used. Usually 35 standard stations are sampled by R/V „Clupea" in daylight during 10 consecutive cruises. At each station herring larvae samples are taken with a MARMAP-Bongo (diameter: 600 mm , mesh size of both nets: 0.315 mm ) by parallel double oblique tows at a speed of 3 knots.

For the calculation of the number of larvae per station and $\mathrm{m}^{2}$, the methods of Smith and Richardson (1977) and Klenz (1993) were used and extended to length-classes. To get the index for the estimation of the year-class strength, the number of larvae which have reached the length of $\mathrm{TL}=30 \mathrm{~mm}$ (larvae after metomorphosis) were calculated taking into consideration growth and mortality.

Further details concerning the surveys and the treatment of the samples are given in Brielmann (1989) and Mueller \& Klenz (1994).

The estimated numbers of larvae for the period 1977 to 1995 are summarized in Table 3.5.10.

### 3.6 Recruitment

### 3.6.1 Indices of $\mathbf{0}$-ringers

Indices of 0-ringer abundance are available from larval surveys at Greifswalder Bodden and adjacent waters during March to June (Table 3.5.10), and from German Bottom Trawl Surveys during November-December in Div. 22-24 (Table 3.5.1). The indices for year classes 1980 to 1996 are compared in Figure 3.6.1.

### 3.6.2 Indices of 1-ringers

Indices of 1-ringer abundance are available from German Bottom Trawl Surveys during November-December in Div. 22-24 (Table 3.5.1) and from German Bottom Trawl Surveys during January-February in Div. 24 (Table 3.5.4). The indices for year classes 1980 to 1995 are compared in Figure 3.6.2.

### 3.6.3 Trend in recruitment

The indices illustrated in Figures 3.6 .1 and 3.6 .2 show the following trends: A poor recruitment of year classes 1980-81 was followed by an increase to a high level of recruitment for year classes 1983-88. From year class

1990 the recruitment declined markedly and has been at a low level since. An increase in year classes 1993-1994 is indicated. The present estimate of the 1996 year class is low compared to historical record.

### 3.7 Data exploration

Catch at age and survey data are presented in Tables 3.3.10, 3.3.11 and 3.5.1-3.5.11. The input data are restricted to the period 1987 and onwards. This restriction in time was decided in last years report (ICES 96/Assess:10) by the fact that splitting of spring and autumn spawners in Divisions IIIa and Subarea IVa was not done before 1987. In light of the problems in the splitting methodology it should be emphasised that the basis for any assessment of the stock relies on questionable catch and survey data.

Natural mortality, maturity ogive and proportions of F and M before spawning were all assumed to remain constant between years. M is assumed to be 0.2 per year, F-prop. 0.1 and M-prop. 0.25 for all age groups. The maturity ogive used was the same as that used at last years Working Group meeting:

| Age | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | $8+$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Maturity | 0 | 0 | .2 | .75 | .9 | 1 | 1 | 1 | 1 |

It was noted that the estimated maturity ogives obtained from acoustic surveys differs between samples taken in the Division IIIa and in the spawning area in Sub-division 22.

Six surveys with age disaggregated data and one larvae survey were available as indices of abundance:
Index 1: IBTS in Div. IIIa, Feb. 1980-1996, 2 and 3+ ringers
Index 2: German bottom trawl survey (GBTS) in SD 22, Nov. 1979-96, 0-3+ ringers
Index 3: German bottom trawl survey (GBTS) in SD 24, Nov. 1978-96, 0-3+ ringers
Index 4: Acoustic. survey in Div IIIa, July 1989-96, 0-8+ ringers
Index 5: Acoustic. survey in SD 22+24, Oct. 1989-96, 0-8+ ringers
Index 6: Larvae survey in SD 24, March-June 1977-1995, 0-group
Index 7: German bottom trawl survey (GBTS) in SD 24, February 1979-96, 1-8+ ringers
The IBTS indicies (Index 1) in February could not be adequately split between spring and autumn spawners (Section 3.2) and only $3+$ ringers were used in the analyses. Indices 2 and 3 basically cover the same stock component in the Baltic with the same methodology. All three surveys are undertaken at the time of the extensive migration from and to the spawning areas in the southern Baltic (ICES 1996/Assess:10). The acoustic survey in Division IIIa (Index 4) coincides with a high expectation of a large proportion of the stock in Division IIIa. The acoustic survey in Sub-divison 22 and 24 (Index 5) mainly covers the Baltic component of the stock. The use of the larvae survey (Index 6) as a biomass index is restricted (Section 3.5.5) but has nevertheless been interpreted as an SSB estimate. The updated bottom trawl survey results from the Baltic during February covers both the Baltic stock component and the immigrating Division IIII stock component.

The estimated yearclass strenght at age 3 varies and is not consistent between surveys (Figure 3.7.1). However, all surveys indicate less abundant yearclasses after 1993 and 1994. Catches indicate a relatively larger 1994 yearclass. The age distribution in the surveys vary, while the age distribution in the catches seems stable. Mean weights at age in the catch varies by quarter according to the migration model (emigration to the Division IIIa in the third quarter of larger individuals). However, there is a conspicuous difference in mean weights between the Baltic and Division IIIa areas indicating that other stock components in the Baltic interfere with the Western Baltic herring (Figure 3.7.2).

Due to the uncertainties in the basic data (stock separation, catch at age) it was agreed not to attempt to make an analytical assessment. The Working Groups has previously explored such attempts in vain. However, simulations with the ICA program was tested in order to elucidate the reliability of input data.

In all ICA runs the following parameters were kept constant:
The weighting factor to all indices (lambda $=1$ ).
The linear catchability model for all indices.
The range of years for separability constraint ( $=6$ )
The reference F at age 4 and the selection 1 for oldest age.

Further details on input parameters for the ICA are presented in Table 3.7.1. Input data on the ICA run is shown in Tables 3.7.2-3.7.6.

Altogether six runs were made with single indices and one run with multiple indices. The results of the runs were compared by using the estimates and standard deviations of the reference F and the SSB in 1996. The estimates of the comparative runs obtained are given below:

| Run | Index | F and SSB (x 1000 t ) in 1996 from ICA |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |
| No. | No. | Index | Mean F | Lower L. | Upper L. | $\underline{S S B}(\mathrm{x} 1000 \mathrm{t})$ |
|  |  |  | 1996 |  |  | 1996 |
| 1 | 2 | GBTS SD 24 Nov | 0.08 | 0.05 | 0.14 | 920 |
| 2 | 3 | GBTS SD 22 Nov | 1.38 | 0.74 | 2.57 | 90 |
| 3 | 4 | Acou. Surv.IIIa+IVaE | 0.20 | 0.13 | 0.31 | 380 |
| 4 | 5 | Acou. Surv. SD 22-24 | 0.07 | 0.05 | 0.09 | 1060 |
| 5 | 6 | Larv. Surv. SD 24 | 0.59 | 0.23 | 1.49 | $170{ }^{1}$ |
| 6 | 7 | GBTS SD 24 Feb | 0.20 | 0.14 | 0.30 | 390 |
| 7 | 4/5/7 | Indices 4, 5 and 7/ 3-8+ ringers | 0.07 | 0.05 | 0.09 | 990 |
| ${ }^{1} 1996$ data not yet available |  |  |  |  |  |  |

As can be seen, the runs by individual indices estimate both unrealistic and plausible fishing mortalities. The estimated SSB levels also appear very uncertain. The indices and catch at age data appear to give no useful information on absolute stock size. It should be stressed that the results from the ICA run are presented only to illustrate the assessment problems. Consequently, no attempt was made to predict the stock size of herring in Division IIIa and Sub-divisions 22-24.

The two hydroacoustic and the botttom trawl survey in Sub-division 22 and 24 seem to agree in time trends. The additional run was made with only age groups 3 to $8+$ included in order to exclude the splitting problem. The result of the run is presented in Tables 3.7.7-3.7.16 and Figures 3.7.3-3.7.5. This run resulted in an extremly low estimate of reference $F(0.07)$ and a correspondingly large spawning biomass ( $990,000 \mathrm{t}$ ).

### 3.8 Stock assessment

Despite the failure to contribute to an analytical assessment the survey and catch data provide information on stock development. CPUE values (in weight) or biomass estimates were available for all indices. The larvae survey was assumed to represent changes in biomass levels. An inspection of these relative stock estimates was interpreted as a stable or slight decrease in the stock over the last six years (Figure 3.8.1). However, the IBTS CPUE (only 3+ included) increased dramatically from 1995 to 1996 in both the Skagerrak and the Kattegatt.

A separable VPA was run on ages 3 to 6 (only spring spawners) from 1987 to 1996 with down-weighting to 0.01 from 1987 to 1990 . F was assumed to be 0.4 and $S$ was set to 1.0 . Results show a random residual pattern. Spawning stock estimates decrease from a peak in 1992 by $1 / 3$ to 1996 . There were no obvious trends in fishing mortalities.

The catch data indicates lower exploitation in 1996 compared to previous years. Catch curves (3-6 WR) averaged over three year periods show a downward trend in total mortality: $\mathrm{Z}=.95$ in 1988 to 1991, $\mathrm{Z}=0.54$ in 1992 to 1993 and $\mathrm{Z}=0.43$ in 1994 to 1996. Similar trends are seen in the acoustic surveys and the Baltic bottom trawl surveys. Assuming equilibrium conditions total mortality calculated for the same three periods drops by $23 \%$ to $67 \%$. Total mortality in the IBTS drops from $\mathrm{Z}=1.15$ in 1992 to 1994 to $\mathrm{Z}=0.92$ in 1995 to 1997. These capricious calculations do not give rise to fears of increasing exploitation rates.

The overall results of the 1996 exercises indicate a stable SSB and slightly decreasing fishing mortality from 1987 and onwards. However, the Working Group members feel that both the data on the commercial fishery and on the surveys are questionable. The assessment trials cannot provide an accurate indication about the development of the stock. As a consequence, predictions of the western Baltic herring were not considered.

### 3.9 Future activities

Since 1993, the Working Group has encountered severe problems in assessing the status of the spring spawners in Division IIIa and Sub-divisions 22, 23 and 24. These problems have repeatedly been described over the past years by the Working Group. The problems can be ascribed to two sources. Firstly, year and age trends are in conflict between survey indices and the commercial catch data. Some of the indices are internally inconsistent, often demonstrating negative mortality. Furthermore, tuning of the catch data by individual surveys has resulted in conflicting estimates of the SSB and fishing mortalities. These incoherent patterns in the input data and in the assessment results were also observed during the 1996 Working Group meeting.

The second cause for concern is the estimate of the proportion of autumn spawners in the total landings in the SW Baltic and Division IIIa. The net transfer of catches of autumn spawners from the Division IIIa to the North Sea stock varies significantly between years.

Division IIIa and Sub-divisions 22-24

| Year | $\mathbf{1 9 8 5}$ | $\mathbf{1 9 8 6}$ | $\mathbf{1 9 8 7}$ | $\mathbf{1 9 8 8}$ | $\mathbf{1 9 8 9}$ | $\mathbf{1 9 9 0}$ | $\mathbf{1 9 9 1}$ | $\mathbf{1 9 9 2}$ | $\mathbf{1 9 9 3}$ | $\mathbf{1 9 9 4}$ | $\mathbf{1 9 9 5}$ | $\mathbf{1 9 9 6}$ |
| :---: | ---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Landings <br> (x 1000 t) | 349 | 308 | 336 | 432 | 286 | 280 | 257 | 311 | 295 | 234 | 231 | 173 |
| Fraction Spring <br> Spawners (\%) | 71 | 60 | 52 | 58 | 65 | 73 | 74 | 54 | 57 | 70 | 75 | 75 |

The uncertain and highly questionable basis for the split between spring and autumn spawners in Division IIIa and Sub-area IVa are reviewed in section 3.2. In view of the important consequences the present splitting method should be reviewed and preferably replaced by other methods. Pilot studies indicate that measurements of otolith increment widths are statistically robust and more cost-efficient (Mosegaard and Madsen, 1996).

The underlying biological model should be evaluated. Prior to 1988 annual assessments were made separately for Division IIIa and the Baltic (Sub-divisions 22-24). The present perception of a unit stock is based on the assumption that spring spawning herring in the Baltic migrate northwards into Division IIIa and the North Sea after spawning in April-May. The return migration to the Baltic spawning grounds occurs by the end of the winter season. The theory is supported by tagging results (Biester, 1979) and by seasonal and spatial observations of vertebrae counts (Rosenberg \& Palmen, 1981). Results from the acoustic estimates from the Baltic Sound (Subdivision 23) suggest that the migration is substantial and rapid (ICES 1996/Assess:10). Thus, the estimated relative biomass in the Sound remained at 400 tx NM -2 from autumn 1993 to April 1994 when the biomass decreased to 20 tx NM .

Existing fishery-independent surveys have not been designed to account for the assumed migration patterns. None of the surveys covered the entire distribution of the stock. Thus, changes in the migration rate or timing between years may have violated the validity of the time series of these surveys. The Baltic larval survey at spawning time and the acoustic survey during summer in Division IIIa would be expected to reflect the SSB better than the other surveys. The acoustic surveys are not consistent with the catch at age distributions and the Baltic larval surveys have a very low precision. The Baltic trawl surveys are conducted at times when migration is assumed to occur (IBTS) or when a main part of the stock is assumed to be at least partially absent from the surveyed area (Baltic trawl surveys). From an assessment point of view a call for a coordination or a larger coverage of these surveys may address these problems.

The above problems will be addressed inter-sessionally but it is unlikely that they will be resolved before the next Working Group meeting. An EU funded co-operation will start on June 1996. The objectives are to evaluate present splitting methods in terms of precision and accuracy. Traditional vertebra counts will be compared with otolith macro and microstructure analyses. The three year project will also subsample and analyse historical otoliths from surveys and catches for a full VPA range (10 years). Ongoing acoustic surveys in the transition area between the Baltic and Division IIIa, the Sound will contribute to further knowledge of the migration pattern of spring spawning herring.

In order to make fruitful contributions towards a full analytical assessment of spring spawners in the Division IIIa and Sub-divisions 22 and 24, the Working Group recommends that a Study Group should set up. The group should meet in Lysekil January 12th to 16th, 1998 (Chairman Jorgen Dalskov) with the following terms of reference:

1. to formulate and test a migration model of the Baltic spring spawning herring that is consistent with present knowledge and which can be used on a routine basis for assessment purposes. The model should be linked to the results of an evaluation of the methodology on separation of stocks.
2. to compare the methodologies for stock discrimination by vertebrae counts or otolith analyses and to update the historical split between spring and autum spawning components in Division IIIa.
3. to review and update catch at age and mean weight at age data for all fishing fleets that catch herring in Division IIIa and Sub-divisions 22 and 24. The task should include the possibility of a revised sampling regime of the affected fleets.
4. to review and test the consistency among existing results from research surveys and to adapt future sampling to the needs of an established migration model.

No indices of spawning biomass to be used.
No of years for separable constraint ? --> 6
Reference age for separable constraint? --> 4
Constant selection pattern model (Y/N) ? -->y
$S$ to be fixed on last age ? --> 1
First age for calculation of reference F --> 3
Last age for calculation of reference $\mathrm{F} \rightarrow->6$
Use default weighting (Y/N)? --> y
Is the last age of FLT04: Acoustic Surv in DIIIa a plus group ?
(Y/N)--> y
Is the last age of FLT05: Acoustic Surv in SD22-24 a plus group? (Y/N)--> y
Is the last age of FLT11: Germ Bott Trawl Sur SD 24 a plus group?
(Y/N)--> y
You must choose a catchability model for each index.
Models: A Absolute: Index =Abundance +e
L Linear: Index $=\mathrm{Q}$. Abundance +e
P Power: Index $=\mathrm{Q}$. Abundance ${ }^{\wedge} \mathrm{K}+\mathrm{e}$
where Q and K are parameters to be estimated, and $e$ is a lognormally-distributed error.

Weighting options :
1 - Recalculate all survey weights iteratively.
2 - Enter survey weights by hand.
Enter your choice --> 2
Enter weight for FLT04: Acoustic Survey in IIIa at age 3 --> 1
Enter weight for FLT04: Acoustic Survey in IIIa at age $4-->1$
Enter weight for FLT04: Acoustic Survey in IIIa at age 5 --> 1
Enter weight for FLT04: Acoustic Survey in IIIa at age $6 \rightarrow->1$
Enter weight for FLT04: Acoustic Survey in IIIa at age $7 \rightarrow 1$
Enter weight for FLT04: Acoustic Survey in IIIa at age $8-->1$
Enter weight for FLT05: Acoustic Surv. in 22-24 at age $3-->1$
Enter weight for FLT05: Acoustic Surv. in 22-24 at age $4-->1$
Enter weight for FLT05: Acoustic Surv. in 22-24 at age $5-->1$
Enter weight for FLT05: Acoustic Surv. in 22-24 at age $6-->1$
Enter weight for FLT05: Acoustic Surv. in 22-24 at age $7-->1$
Enter weight for FLT05: Acoustic Surv. in 22-24 at age $8-->1$
Enter weight for FLT11: Germ Bott T Su SD 24 Feb age 3 --> 1
Enter weight for FLT11: Germ Bott T Su SD 24 Feb age 4 --> 1
Enter weight for FLT11: Germ Bott T Su SD 24 Feb age 5 --> 1
Enter weight for FLT11: Germ Bott T Su SD 24 Feb age 6 --> 1
Enter weight for FLT11: Germ Bott T Su SD 24 Feb age 7 --> 1
Enter weight for FLT11: Germ Bott T Su SD 24 Feb age 8 --> 1
You should enter estimates of the extent to which errors in each age of the age structured indices
are correlated. These may range from zero
(independence) to 1 (correlated errors).
Enter value for aged index $1-->1$
Enter value for aged index $2-->1$
Enter value for aged index 3 --> 1
Do you want to shrink the final populations? (Y/N) --> n

Model for FLT04: Acoustic Surv in Div IIIa is to be (A/L/P) ?--> 1
Model for FLT05: Acoustic Surv in SD 22-24 is to be (A/L/P) ?--> 1
Model for FLT11: Ger Bott Tra Su SD 24 Feb is to be (A/L/P) ?--> 1
Fit a stock-recruit relationship (Y/N) ? --> n
Enter lowest feasible F --> . 05
Enter highest feasible F --> 1
No of years for separable analysis : 6
Age range in the analysis : 38
Year range in the analysis : 19871996
Number of indices of SSB : 0
Number of age-structured indices : 3
Parameters to estimate : 37
Number of observations : 183
Conventional single selection vector model to be fitted.

### 4.1 Introduction

The herring fisheries to the south of Ireland in the Celtic Sea and in Division VIIj have been considered to exploit the same stock. For the purpose of stock assessment and management these areas have been combined since 1982. The areas for which the assessments are now made, together with the area for which the TAC is set by the EU is shown in Figure 4.1.1. It should be noted that, although the management unit covers all of Divisions VIIg,h,j and $k$ and the southern part of Division VIIa, the total Irish catch which constitutes over $95 \%$ of the catch from this entire management unit is taken from the inshore waters along the Irish coast.

### 4.2 The Fishery in 1996-1997

### 4.2.1 Advice and management applicable to 1996 and 1997

In 1995 ACFM reacted to the apparent decrease in stock in the area and recommended that F should be reduced in 1996 by $60 \%$ of the 1994 value, corresponding to a catch of only $9,800 \mathrm{t}$. The EU subsequently introduced a TAC for 1996 of $16,500 \mathrm{t}$. This was subsequently increased to $21,000 \mathrm{t}$ by the EU following the results of the May 1996 meeting of ACFM.

ACFM did not give specific advice for the fishery for 1997 as the stock was considered to be within safe biological limits. The TAC set by the EU for 1997 was for a catch of $22,000 \mathrm{t}$.

The spawning box closure system, which was first introduced in the late eighties and which is described in ICES (CM1989/Assess:15) was again continued during the 1996/97 season - the box closed being that in Division VIIaS. This was closed for a forthnight in January 1997. The entire Irish fishery was again closed from midFebruary 1996 through to early October 1997.

The total Irish quota was subdivided into boat quotas on a week by week basis. All vessels were again regulated by licences which restrict landings to specific ports and to specific times.

### 4.2.2 The fishery in 1996/1997

As has been the case for a number of years the major portion of the catches in this area was taken by the Irish fishery during the spawning season which normally lasts from October to February. This fishery is directed to the Japanese roe market.

During the period October 1996 to December 1996 shoals appeared to be very abundant throughout all areas particularly on the inshore spawning grounds. Unusually large shoals were also reported during January and early February on the important spawning grounds in Division VIIa (South). Shoals were also abundant in Dingle Bay (Division VIIj) in January and early February. It has been pointed out by recent Working Groups that there appears to have been a continued increase in the abundance of fish from this area i.e. Division VIIj at this time in recent years. The Irish fishery was closed early in February 1997 because of difficulties in disposing of the catch. For this reason the final catch figures for the season were lower than those of recent seasons.

The maximum number of Irish vessels participating in the 1996/1997 fishery was 70 which was an increase on the numbers ( approximately 65) which participated from 1993 to 1995.

The distribution of the total international herring catches ( t ) in Sub-areas VI and VII per quarter per statistical rectangle, based on the logbooks and not corrected for misreporting is shown in Figure 4.2.1 a-d.

### 4.2.3 The catch data

The estimated national catches from 1987-1996 for the combined areas by year and by season (1 April-31 March) are given in Tables 4.2.1 and 4.2.2 respectively. The total catches for the fishery over the longer period from 1958 to 1996 are shown in Figure 4.4.2. The reported catch including the estimates of discards and unallocated landings, taken during the $1996 / 1997$ season was over $17,000 \mathrm{t}$ compared with $23,300 \mathrm{t}$ during the previous season. The decrease was mainly due to marketing difficulties during early 1997 and a reduced level of discards. Landings from this fishery have been stable for a number of years and have averaged about $19,000 \mathrm{t}$
since 1985. Nearly $2,000 \mathrm{t}$ were reported as having been taken in this area during 1996 but were in fact taken in the other areas.

## Discards

The level of discards in this fishery is believed to have decreased in recent years as fishermen have become more expert in identifying suitable shoals for the Japanese roe market and in controlling the amounts of fish in their nets. Nevertheless, discards may on occasions reach a high level particularly if the fishery is allowed to remain open despite marketing difficulties. During the first quarter of 1997 the landings from Division VIIa(South) and Division VIIg were raised by $10 \%$ to include discards as in previous years. The level of discards for the remainder of the season is not believed to have been significant.

The results of an EU funded project (EU Project BIOECO/93/17) indicate that the overall discard rate of $10 \%$ $20 \%$ used by previous Working Groups is realistic.

### 4.2.4 Quality of catch and biological data

Management authorities are confident that the accuracy of the landing statistics from this fishery has increased considerably in recent years. There have, however, been persistent but unconfirmed reports that the overall catch figure may be considerably underestimated. Misreporting of catches from Division VIIj to Division VIIb, which had been a problem, has decreased in recent years. However as mentioned above there has been an increase in the amounts of catches misreported from other areas. Biological sampling of the catches throughout the area continues to be satisfactory and at a high level. Details of the sampling data per quarter are shown in Table 4.2.3, while the length distributions of the catches taken by the Irish fleet per quarter are shown in Table 4.2.4.

### 4.2.5 Catches in numbers at age

The total catches in numbers at age, including discards, per season from 1958 to 1996 are shown in Table 4.2.5. The catch during 1996/1997 was dominated by 2.w.ring fish (the 1993/1994 year class). The 1992/93 year class, which dominated the catches during 1995/96 season was again well represented. The 1990/91 year class which was considered to be a strong year class still represents over $12 \%$ of the total catch.

### 4.3 Mean weights at age

As the major portion of the catch from this fishery continues to be taken during the spawning season the mean weights at age in the catches have traditionally been taken as the mean weights in the stock at spawning time ( 1 October). The mean weights from 1958 to 1996. are shown in Table 4.3.1. The mean weights appear to be reasonably stable although there has been a decrease of approximately $10 \%$ in the values of the $1-3 \mathrm{w}$. ring fish in recent years.

### 4.4 Stock assessments

### 4.4.1 Acoustic surveys

Acoustic surveys have been carried out on this stock each season since 1989/1990. Two surveys have been carried out each season and the surveys were designed to estimate the size of the autumn and winter spawning components separately The total stock has been considered to be the sum of the stocks estimated from both surveys - the different components being separated on the basis of maturity stages. It was again intended to carry out two surveys in 1996/97 but due to unforeseen circumstances it was not possible to carry out the January 1997 survey.

The survey, carried out in October 1996, the results of which were presented in a working document (Molloy, and Fernandes, W.D.1997), was severely disrupted by abnormally bad weather. The survey did not therefore cover the important areas in Division VIIj in which considerable catches were taken in the commercial fishery. It was originally intended that the transects in this survey should extend out as far as 50 miles offshore because of the occurrence of offshore concentrations evident during the 1996 surveys. However, this was not achieved because of time restraints and most of the transects extended only to 20 miles off shore. During this survey unusually large concentrations of herring were located on the spawning grounds along the Irish coast. These concentrations were positively identified as herring from fishing trawls and by the commercial fleet. Considerable
confidence is therefore attached to the estimates obtained during the survey. The shoals were dominated by fish from the 1993/94 year class as also were the catches taken from the commercial fishery.

The total stock size estimated to be in this areas at the time of the survey was $150,000 \mathrm{t}$ which was the highest estimate recorded since these surveys were commenced in 1989. The total spawning stock was estimated to be $143,000 \mathrm{t}$. Although the stock size as estimated from the acoustic survey is the highest recorded it may be even higher because no coverage was possible in Division VIIj. The high stock size is consistent with reports from fishermen who have suggested that there has been a very large increase in this stock in recent years.

The age disaggregated data for this stock, estimated at the time of the survey, and including a small amount of commercial catch ( $1,500 \mathrm{t}$ ) taken prior to the survey is shown in Table 4.4.1 and is compared with similar data for the previous surveys. The age distribution indicates that the 1993/94 year class is the strongest one to enter the fishery since 1990. It is also clear that the numbers of two year old fish is higher than the numbers of one year olds in the preceding year in all cases except for 1994 indicating that some recruitment is coming from outside the survey area. Again there is a considerable reduction in the numbers of 0 -group fish in recent years because of the inadequate coverage in Division VIIj.

### 4.4.2 Results of Assessments

The integrated catch analysis program (See Section 1.5 ) has been used since 1994 to estimate the fishing mortality and the size of the stock. In these analyses the age-disaggregated data from the acoustic surveys from 1990 to 1996 have been used as the only tuning index available. The 0 and 1 -ring fish are excluded from the analyses as they are not believed to be fully recruited to the Celtic Sea from Division VIIa (North). The analyses carried out at the 1994 Working Group meeting indicated that using the acoustic surveys as a proportional index of stock abundance provided the best fit to the ICA model. This approach has again been adopted and the results of this run are shown in Table 4.4.2 and the diagnostics from the ICA model are shown in Figures 4.4.1, to 4.4.11.

The spawning stock biomass estimated by the ICA model for 1996 is $67,500 \mathrm{t}$ compared with $71,400 \mathrm{t}$ for 1995 . The value of $F$ estimated for 1996 is 0.38 which is the lowest value for this stock since 1979 and may be explained by the low catch in 1996/97. The ICA model indicates that the recruitment of the 1992/93 year class, while strong, is not as strong as either the 1992 or 1990 year class. A comparison between the estimates of SSB obtained from the ICAs carried out since 1994 and the SSBs obtained from the acoustic surveys is shown below.

| Season | Acoustic <br> surveys | ICA in 1994 | ICA in 1995 | ICA in 1996 | ICA in 1997 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1990 | 91000 | 65300 | 57500 | 65000 | 66000 |
| 1991 | 77000 | 55000 | 45600 | 55700 | 56800 |
| 1992 | 71000 | 61600 | 44800 | 57300 | 59600 |
| 1993 | 90000 | 62500 | 41200 | 55200 | 58200 |
| 1994 | 50600 | $59100^{*}$ | 45000 | 67800 | 67900 |
| 1995 | 114000 | $59700^{*}$ | $42700^{*}$ | 86000 | 71400 |
| 1996 | 142000 | $60000^{*}$ | $35000^{*}$ | $93000^{*}$ | 67500 |
| 1997 |  |  |  |  |  |

*predicted values
The SSBs estimated from the acoustic surveys suggest that the stock has increased considerably in recent years. The overall trend from the most recent ICA suggest that the stock has been stable but at a lower level than that indicated from the acoustic surveys.

Despite these considerable differences, the diagnostics from the ICA model suggest that there is a good fit between the acoustic age-disaggregated data and the catch at age data although there is evidence to suggest that in 1996 the acoustic survey overestimated the abundance of the 1993/94 year class in comparison with the abundance suggested from the numbers of that year class in the catches. This year class represented $60 \%$ of the stock as estimated from the acoustic survey but only $48 \%$ of the numbers in the catches. An examination of the age distribution of the catches did not indicate any change in the exploitation pattern in the 1996/97 season and there was no evidence to show that the restrictions in the January fishery or the premature closing of the fishery in February due to marketing difficulties resulted in a decreased proportion of the 1993/94 year class in the overall catches.

The effects of the low stock estimate obtained from the 1994/95 survey on the overall development of the stock was investigated by rerunning the ICA model but omitting the results from this survey. However the differences were not substantial. It was therefore decided to accept the assessment using the full data set.

### 4.5 Recruitment estimates

There are no recruitment indices available for this stock which can be used for predictive purposes. The numbers of 1 -ring fish derived from the 1997 ICA model are shown in Figure 4.4.2. There has been no apparent trend in recent years and recruitment has fluctuated considerably The geometric mean value over the period 1983-1995 was taken as the most realistic value to use for predictive purposes. The value for the 1993 year class was not included as it is based on limited data. The resultant value was 543 million, compared with values of 535 million and 517 million used in the prediction carried out in 1995 and 1996.

### 4.6 Short-term Projections

Short-term projections were carried out for the following two scenarios:

## 1. A total catch in 1997 of $22,000 \mathrm{t}$ i.e. the agreed TAC. A range of F factors is then presented for 1998 .

The input data for the predictions are shown in Table 4.6.1.and the results are shown in Tables 4.6.2.
2. A total catch in 1997 of $22,000 \mathrm{t}$ followed by continuation of fishing in 1998 and 1999 at an F level in both years equal to that of 1996 i.e. $=0.375$.

The results of this projection is shown in Table 4.6 .3 and the detailed output is shown in Table 4.6.4. The yield/ recruit curve is shown in Fig 4.6.1.

The total SSB estimated by the ICA for 1996 was $67,500 \mathrm{t}$ and this was predicted to be at the same level in 1997. If a similar catch level is maintained in 1997 the SSB will decrease slightly to $64,000 \mathrm{t}$ and the F level will be about 0.48 .

A continuation of F in 1998 and 1999 at the same level of 1996 will generate catches on between $18,000 \mathrm{t}$ and $19,000 \mathrm{t}$ and the SSB will be about $69,000 \mathrm{t}$ in both years.

The general conclusions from the short term projection indicate that catches during 1997 to 1999 in the range of $18,000 \mathrm{t}-22,000 \mathrm{t}$ will result in a maintenance of the SSB at about the present level.

The results of the projections show stock sizes that are lower than those estimated in the previous assessment when the predicted stock sizes were $90,000 \mathrm{t}$. They are also considerably lower than those indicated by the trend in the results from the acoustic surveys in 1995 and 1996. The differences in the ICA estimates are as a result of the low numbers of 2.w.ring fish ( the 1994/95 year class) in the population estimates for 1997 compared with the numbers of 2 w . ring fish in the population in 1996. These numbers in 1997 were generated by the catches of this year class in the 1996/97 season and they may not have been fully represented as the fishery was prematurely closed. It is therefore not possible to say anything about the relative abundance of this year class.If it is assumed however to have been at the average recruitment level of 534 million fish then it would have appeared in the population at 1 January 1997 at around 198 million fish instead of 168 million as estimated for the prediction. This would produce an increase in the predicted SSB for 1998 from $66,700 \mathrm{t}$ to $69,600 \mathrm{t}$, assuming a continuation of an $F$ level of that in 1996 (i.e $=0.375$ ).

### 4.7 Medium Term Predictions and Safe biological limits

The MBAL and the stock recruitment relationship for this stock were investigated in detail by the 1996 Working Group. The MBAL was defined at about $40,000 \mathrm{t}$ i.e $1 / 3$ of the stock level in a period when it was relatively lightly exploited. For this stock it must again be emphasised that there is no period over the timespan 1958-1997 when F values were lowere than about .35 for more than a few years continuously. To study the future development of the stock a prediction was carried out for the period 1997-2007, assuming average recruitment and catches of about $20,000 \mathrm{t}$. The results show that over this period the stock remains at about the present level while the fishing level also remains at about the 1996 level(=.39). It, therefore seems reasonable to assume that a
catch level of $20,000 \mathrm{t}$ per annum is a safe level for this stock. The results of this prediction are shown in Table 4.6.5.

### 4.8 Management Considerations

The present assessment indicates that this stock is in a stable condition and should be able to sustain the present catch level. The development of the stock in the immediate future is largely dependent on the strength of the 1994/95 and 1993/94 year classes. The 1994/95 year class appears to be relatively low, based on the age distribution of the 1996/97 catches, while on the other hand the 1993/94 year class appears to have been very strong, based on the results of the acoustic survey. There is therefore considerable uncertainty on the development of the stock in the immediate future and this would suggest a cautious management of the fishery.

The major fleet which exploits this stock is capable of generating a very high fishing mortality - particularly as the main fishery takes place for spawning shoals on the spawning beds. The catching power of this fleet is extremely high in relation to the TAC and consideration should be given to reducing the number of vessels that participate in the fishery.

It is extremely important that the fishery should continue to be effectively monitored. This can not be done without adequate survey data and in this respect it is recommended that sufficient resources be made available to enable the acoustic surveys to be maintained.

Table 4.2.1 Celtic Sea and Division VIIj HERRING landings by calendar year (t), 1987-1996. (Data provided by Working Group members.)

These figures may not in all cases correspond to the official statistics and cannot be used for management purposes.

## ing South and South West of Ireland (Celtic Sea + 19-3-1997 Yield and Spawning Stock Biomass

Figure 4.6.1 (I.C.A. run 10)

### 5.1 Division VIa (North)

### 5.1.1 ACFM Advice applicable to 1996 and 1997

ACFM advice in 1996 recommended a precautionary TAC based on the expected catch levels to discourage misreporting from other areas. The agreed precautionary TACs were 83570 t in 1996 and 83570 t in 1997.

### 5.1.2 The fishery

Estimated catches by participating nations for 1996 are given in Table 5.1.1. Reported catches were 82112 t compared with the agreed TAC of 83570 t . This is the eighth year in succession in which the TAC was not reached, but the TACs have been increased for the last two years.

Continued difficulties with catch reporting exist, with many examples of vessels operating and landing herring catches distant from Division $\mathrm{VIa}(\mathrm{N})$ but reporting catches from that area. The problem is particularly acute during the peak months of the herring fishery around Shetland (August to October). The level of misreporting was assessed to be approximately $68 \%$ of the total catch, leading to an estimated catch of 26105 t for Division VIa(N). Some misreported catches were reallocated to $\operatorname{Division~} \operatorname{VIa}(\mathrm{S})$ and all catches from east of $5^{\circ} \mathrm{W}$ were assigned to Division IVa.

The herring fishery in Division $\operatorname{VIa}(\mathrm{N})$ takes place in two main areas. Certain vessels fish inshore for smaller younger herring, whilst other vessels fish offshore in deeper waters where the fish are larger and older. The distribution of the total international herring catches (t) in Sub-areas VI and VII per quarter per statistical rectangle, based on the logbooks, and not corrected for misreporting is shown in Figure 4.2.1 a-d.

### 5.1.3 Catch in numbers at age

Age composition data of commercial catches, for 1996, were available primarily from Scotland (quarters 1, 3 and 4), Germany (quarters 1 and 3) and Ireland (quarter 3) with two additional samples from Northern Ireland and The Netherlands (Table 5.1.2). The German sample data provided extensive age information but did not include any mean weights at age, the Netherlands data provided age and mean weights but from only 25 fish. Both the German and the Netherlands' samples included a higher proportion of older fish and a reduced proportion of younger fish compared with the Scottish samples.

So as to consider the effect of the different age at length data on the stock estimation procedure, two estimates of catch at age were made. The first estimate used the Scottish age-length and mean weight at age data on the entire catch. The second estimate used the Scottish data on the Scottish catches, and the Netherlands' and German agelength data and the Netherlands' mean weight at age data on all other catches. Due to the patchy nature of sampling, certain assumptions were made for the second estimate:

- the mean weight at age data from the Netherlands' sample (taken from 25 fish in the third quarter) were used to infer weight at age estimates for catches in the other quarters, assuming the same proportional change in weight as found in the Scottish data
- the mean weights from the Netherlands' sample were then applied to the German age data

The estimates are shown in Table 5.1.3. The inclusion of the German age and Netherlands' age data substantially increased the proportion of age $9+$ fish in the catch. Following the comparisons described in section 5.1.8, it was decided to use the second estimate as the final catch at age estimate. It is important in the future, that additional weight information be collected from the offshore catches. The estimated catches in numbers at age back to 1970 (including misreporting) are given in Table 5.1.4.

### 5.1.4 Larvae surveys

Larvae surveys for this stock have been discontinued and no new information is available since 1994. As the larval survey indices of abundance will again be used in the assessment the available information has been reproduced in

Table 5.1.5 for convenience. Details of the survey are given in the 1994 report of the Working Group (ICES 1994/Assess: 13).

### 5.1.5 Acoustic survey

Historical acoustic survey information documented in the 1995 Working Group report have been used. The time series has been updated to include information from the most recent survey (Table 5.1.6).

An acoustic survey of Division VIa (N) was completed from 13 to 30 July 1996 using a chartered fishing vessel. Prior to 1994, a single unstratified transect design was used for the surveys. In 1994, this was changed to a two-level stratified design, in order to reflect perceptions of fish aggregation observed in previous years. In 1996 three levels of stratification were used (Transect spacing $=4,7.5$ or 15 nautical mile as in 1995), and chosen to reflect perceptions of historical stock abundance in the area from 1992 to 1995 . Prior analyses have shown that the stock size estimate is highly sensitive to a small number of observations of very dense shoals. Survey precision should therefore be improved substantially if more survey effort can be allocated to areas of high fish abundance.

Thirty nine trawl hauls were shot on the echo traces, of which 21 captured more than 100 herring. The age structure was dominated by 3-ring herring with an apparent shortage of 2-ring fish. The age-structure of the stock is consistent with that observed in the 1992-1996 surveys. Some problems in identification were noted and it is possible that some traces that contained herring were not included in the estimate. Echo-traces were allocated among the following categories, where the percentage in brackets indicates the contribution by number of each category to the biomass estimate.

1. Herring ( $82 \%$ of estimate)
2. Likely to be herring ( $11 \%$ of estimate )
3. Herring found in mixtures( $7 \%$ of estimate)
4. Unlikely to be herring (would add $80 \%$ to stock estimate if included)
5. Known not be herring (not calculated)

The spawning biomass of the stock was estimated to be $370,300 \mathrm{t}$ compared with $452,000 \mathrm{t}$ in 1995 . The value in 1993 was substantially greater. It is thought that the 1993 survey returned an exceptionally high stock estimate, possibly on account of a strongly contagious distribution. The spatial distribution of the herring stock found in the survey is shown in Figures 2.4.1. and 2.4.2.

In fitting the age-structured models to the survey data it was again assumed that $40 \%$ of annual mortality had been incurred before the surveys. This figure was calculated by assuming that natural mortality is constant throughout the year, and that fishing mortality can be apportioned in the ratio of seasonal catches in 1993.

### 5.1.6 Mean weight at age

Weight at age data from the 1996 fishery were available from Scotland, The Netherlands and Ireland. Mean estimates weighted by the reported catches in number are given in Table 5.1.7, together with comparable historic information. Mean weights at age of the five years of acoustic surveys are also given in of Table 5.1.7.

### 5.1.7 Maturity ogive

Historically, a value of 1 was used as the proportion of mature 2 and 3 ringers. The last five years of acoustic surveys of Division VIa $(\mathrm{N})$ highlighted that a value of 1 was too high for both 2 and 3 ringers. As a result, in the present assessment, the proportion of mature fish back to 1992 was determined by data from the acoustic surveys (Table 5.1.8). The mean proportion of mature fish from 1992-1996 was used for years prior to 1992 ( 0.57 for 2 and 0.96 for 3 ringers).

### 5.1.8 Data exploration and preliminary modelling

As in 1995, the reported catches were thought to contain large amounts of misreported data. Discussions with industry representatives and with pelagic fishery enforcement officers lend credence to the belief that by excluding these catch reports, a much better representation of the true catches is likely to be achieved. However, by the very nature of the problem, it is not possible to define a reliable criterion for reallocating misreported catches. Hence
whilst all the assessments were carried out using the estimated catches for Division VIa(N), a large degree of uncertainty still exists about the reliability of the results.

A range of different models were fitted separately in order to examine the effect of the two estimates of catch at age, and the sensitivity of the fitted population parameters on prior assumptions about survey catchability. All models used the following components with equal weighting:

1. acoustic surveys as proportional linear estimates of stock size
2. larvae abundance indices as power indices of stock size

The survey data and models tested were:

1. catch at age and mean weight at age data with the Scottish samples applied to all catches
2. gradual change in the selection pattern (separable constraint) for 1992-1996
3. the acoustic survey from 1993 removed as part of the acoustic index
4. catch at age and mean weight at age data from a combination of Scottish, German and Netherlands' samples applied to catches by fishing area.

The first run used the catch at age and mean weights from only the Scottish catches, which where well sampled throughout the year and contributed more than $50 \%$ of the estimated catch. Examination of the diagnostics indicated a number of problems; the three indices had minima in the reference $F$ ranging from 0.7 to 0.2 , there was a high peak in the selection pattern at 2 ring and a change in residuals at 2 ring over the period 1991 to 1996.

It was noted that the acoustic survey in 1993 showed a very high positive residual and that the age structure changes observed in the series from 1992 to 1994 did not support this change. In order to examine the impact of this point it was removed from the time series and run 3 was carried out. There was no appreciable difference in F or the SSB when this point was included or removed. Therefore the value was included in the series.

Examination of the diagnostics showed a peak in the selection pattern at 2, dropping to 1 at age 4 (the reference age) and flat from 5 to $9+$. The map of residuals showed changing residuals with time for 2 ring herring. The fishery is known to consist of a Scottish fleet catching predominantly 2 and 3 ring fish and a shelf edge fleet catching older fish. These factors indicate that a changing selection pattern may be more appropriate and a gradual changing selection pattern was allowed within the ICA. The resulting run showed; little improvement in the residuals, elevated 2 ring herring in 1996 (which was not supported by the surveys) and also produced an unreasonable recruitment of 1 ring herring in 1996. The relaxation of the constraint was considered to give unreliable results and therefore excluded from the assessment.

In 1995 the stock recruit relationship was examined in detail (ICES 1996/Assess:10) and it was concluded that "neither stock recruit relationship (Ricker or Beverton and Holt) fitted better to the observations than a simple geometric mean recruitment". On this basis no stock recruit relationship was included.

The incorporation of the sample data from the shelf edge catches by the German and Netherlands' fleets reduced the overall sum of squares in the model fit and improved the alignment between the minima in the different tuning indices in the ICA. On this basis it was assumed that these samples should be included despite their poorly estimated mean weight at age, and this model has been used for reference purposes.

A comparison of the F and SSB for the last 7 years for these four options described above can be seen in Figures 5.1.1 and 5.1.2 respectively.

### 5.1.9 Stock Assessment

The second model tested was used as the 'baseline' assessment and has been used as the reference model for the calculation of short- and medium-term projections. The following variables are defined as:

```
a,y - age and year subscripts
C Catch in number at age and year
C' Catch in number at age and year predicted by the structural model
SSB Spawning stock size in the structural model
LAI Larval abundance index
```

ACOUST Acoustic survey estimates of abundance at age Population abundance in the structural model SSB Spawning stock biomass in the structural model
QLAI Coefficient of proportionality for larvae survey estimates of stock abundance
Qacu $\quad$ Coefficient of proportionality for acoustic survey estimates of stock abundance
K Power coefficient for the LAI estimate of stock abundance
$\lambda \quad$ Weighting factor $=0.1$ for age 1 and 1 for all other ages.

The assessment model was fitted by a least-squares minimisation of:

$$
\begin{gathered}
\sum_{a, y}\left(\log \left(C_{a, y}\right)-\log \left(C_{a, y}^{\prime}\right)\right)^{2}+ \\
\sum_{y}\left(\log \left(Q_{L A I} S S B_{y}^{K}\right)-\log \left(L A I_{y}\right)\right)^{2}+ \\
\lambda_{a} \sum_{a, y}\left(\log \left(Q_{A C U, a} N_{a, y}^{*}\right)-\log \left(\text { ACOUST }_{a, y}\right)\right)^{2}
\end{gathered}
$$

This is the same assessment model as that used by the Working Group in 1994 and in 1995. Except that a stock recruit model was excluded. Detailed results of this assessment are given in Table 5.1.9. and in Figures 5.1.3-5.1.15.

Salient points of the assessment are:

1. Fishing mortality in 1996 was low, and in the range 0.05 to 0.21 (parameter $95 \%$ C.I.s)
2. Incidence of 2 ringers in the acoustic survey were unusually low in 1996.
3. 1-ringers are still highly variable in the acoustic index.
4. Assumptions of log-normality in the index observations are not demonstrably violated.
5. Fishing mortality is estimated to have stopped declining or may now be slightly increasing following a declining trend from 1986 to 1994.
6. The assumption of a fixed selection pattern over the last 6 years is not supported by the catch data.
7. The estimate of the absolute level of the SSB poorly established.

The assessment merits further comment. There was a large catch of 2-ringers included in the catch at age matrix for 1995, and this translated into a perception of increased selection at this age which was of concern last year. However, the acoustic survey has confirmed an unusually abundant 1992 year class which supports the sample reallocation (section 5.1.3). It is possible that due to the misreporting problem there has been some confusion about the origin of samples and it is likely that in some cases a North Sea age-structure has been used to allocate catches to age for the Division VIa $(\mathrm{N})$ stock. Therefore, the apparent change in selection may be due to sampling problems or a change in the relative proportions of the Scottish and shelf edge fisheries.

In the present assessment, the estimated fishing mortality is below the assumed natural mortality for ages $1,2 \& 3$ and similar to that for 4 to $9+$. This means the assessment is very strongly dependent on the assumed value of $M$, and provides only limited information on the state of the stock. It is suggested that the assessment be treated as an indication that the stock is lightly exploited. Quantitative estimates of fishing mortality provided here are likely to be of limited value. Summaries of F, yield, recruitment and SSB are shown in Figure 5.1.16.

### 5.1.10 Short-term projections

Conventional short term catch projections were calculated on the following basis:

- Fishing mortality in 1997 = Fishing mortality in 1996
- Starting populations on 1 January 1997 = Population model estimates, except for age 2 for which a geometric mean of population abundance from 1985 to 1995; also used for 1998 and 1999 recruitment.
- Historic mean weights at age from 1993 to 1996 were used for both the stock weights and the catch weights.
- The exploitation pattern used for the projections was that estimated by the population model, and fishing mortality in 1996 was used as a reference value for the projections.

Input data for the projections are given in Table 5.1.10, and the consequences of fishing at different levels of fishing mortality (in terms of catch and spawning biomass) are given in Table 5.1.11.

At present there is no reason to suspect major changes in F , therefore at recent levels of fishing mortality $\left(\mathrm{F}_{(96)}\right)$, status quo catches (Table 5.1.12) are predicted to be of the order of $30,000 \mathrm{t}$. At this level of fishing mortality the SSB should gradually increase.

### 5.1.11 MBAL and Stock-Recruit considerations

Considerations of an appropriate level for the minimum biologically acceptable level (MBAL) of spawning stock size was explored in ICES (1996/Assess:10). This year because the assessment was carried out with a different maturity ogive, derived from measured maturity in the population, MBAL was re-calculated using a precautionary measure which defines the MBAL as one-third of the unexploited stock size.

Unexploited stock size cannot be calculated directly but was approximated by calculating the equilibrium stock size for zero fishing mortality under the following conditions:

- Expected recruitment is calculated as $\operatorname{Rexp}\left(\sigma^{2} / 2\right)$ where R represents the geometric mean recruitment from 1976 to 1995 and $\sigma^{2}$ represents the variance of $\ln$ (recruitment).
- Arithmetic mean weights at age in the stock, 1990 to 1996
- Assumed values of maturity and natural mortality as used by the Working Group.

This calculation (using ages 1 to 9 ) leads to an estimate of unexploited equilibrium stock size of some $430,000 \mathrm{t}$. Taking one-third of this level (see section 5.1.11; ICES (1996/Assess: 10) and rounding appropriately leads to an indicative MBAL of $140,000 \mathrm{t}$. For comparison, estimates of historical stock size range from $53,000 \mathrm{t}$ to $245,000 \mathrm{t}$. The SSB in 1996 is estimated to be $194,000 \mathrm{t}$. Despite being below the MBAL for about nine years in the mid 1970s to the mid 1980s there was no apparent adverse effect on recruitment. Further work to address the problem of setting an appropriate MBAL for this stock is required.

### 5.1.12 Medium-term projections

A medium-term projection indicates a low risk for the stock if fishing continues at recent levels with only a $29 \%$ chance of falling below the $140,000 \mathrm{t}$ in 2004.

The method used to calculate medium-term projections is as described by ICES (1996/Assess:7). A Monte-Carlo method was used, with a conventional stock projection being used for each iteration. Projections were F-constrained. The generation of pseudo-data sets for the projections was performed separately for the population parameters derived from the stock assessment and for the generation of future recruitments.

Population parameters (vector of abundance at age in 1996, fishing mortality at reference age in 1996, selection at age) were drawn from a multivariate normal distribution with mean equal to the values estimated in the stock assessment model (Section 5.1.9), and with covariance as estimated in the same model fit. Pseudo-recruitments for subsequent years were generated by calculating a simple geometric mean recruitment because of the failure to identify a usable stock-recruit relationship and resampling randomly from the residuals according to a conventional non-parametric bootstrap method.

The 'ICP3' program was used to implement the calculations.
Weights at age in the catch and in the stock, maturity ogives and natural mortality were as given in Section 5.1.10. Only one scenario was examined: Exploitation at recent levels of fishing mortality. The fishing mortality in 1997 was constrained at its estimated value for 1996. This projection indicates very little change in stock size for fishing at the 1996 fishing mortality (Figure 5.1.17).

### 5.1.13 Consistency of Assessments

It is not possible to calculate an informative retrospective analysis for this stock, as the assessments are heavily dependent on a short time-series of acoustic survey data. Thus, deleting recent data leaves a data set which is too small for a comparable analysis to be calculated. A summary of estimates of fishing mortality made in recent assessments shows that there has been a marked downwards revision in the fishing mortality estimate Figure 5.1.1. This is clearly due to the new perception that catches from this stock in recent years have probably been about half of the reported levels. In addition there is a reduction in the SSB over the full time series from last years assessment due to the inclusion of a maturity ogive of $57 \%$ at 2 ring and $96 \%$ at 3 ring compared with $100 \%$ for both age groups for
the previous assessments. The perception is that the stock dynamics are not strongly dependant on the model structure. However, the recent changes in the selection pattern are a concern.

### 5.1.14 Management Considerations

The assessment calculation presented here indicates that this is a lightly exploited stock. The modelling approaches used indicate that continued fishing at recent levels is likely to result in catches around $30,000 \mathrm{t}$, and to present little risk of a stock decline.

### 5.2 Clyde Herring

### 5.2.1 Advice and management applicable to 1996 and 1997

Management of herring in the Clyde is complicated by the presence of two virtually indistinguishable stocks; a resident spring-spawning population and the immigrant autumn-spawning component. In recent years management strategies have been directed towards rebuilding the highly depleted spring-spawning component to historical levels.

The measures which remain in force in order to protect the indigenous spring-spawning stock are;

- A complete ban on herring fishing from 1 January to 30 April.
- A complete ban on all forms of active fishing from 1 February to 1 April, on the Ballantrae Bank spawning grounds, to protect the demersal spawn and prevent disturbance of the spawning shoals.
- The TAC in 1996 was maintained at the same level as in recent years ( 1,000 tonnes).

### 5.2.2 The fishery in 1996

Annual landings from 1955 to 1996 are presented in Table 5.2.1. Landings in 1996 were 881 t which is more than double the recorded landing in the previous year. Landings by the local fleet increased from 392 t in 1995 to 598 t in 1996. A total of 283 t was taken by Northern Ireland vessels landing into either Northern Ireland or the Isle of Man. This is the first time since 1985 that landings by UK vessels, other than those from Scotland, have been reported from this area. Most of the landings were in the third quarter of the year with more than half ( 568 t ) taken by Scottish pair trawlers. In 1995 this directed fishery took place later, during October and November. The proportions of spring and autumn spawners in these landings could not be estimated.

Sampling levels in the local fishery have been reduced to almost half the levels of recent years but are still well above recommended levels (Table 5.2.2). Samples were taken from both the Scottish and the Northern Ireland fleet landings.

An index of effort (E), based solely on the Scottish pair trawler fleet, has been calculated for comparison with previous years as follows;

$$
E=E_{p} \cdot L / L_{p}
$$

where $E_{p}=$ days absent by Scottish pair trawlers.
$\mathrm{L}=$ total landings in tonnes.
$\mathrm{L}_{\mathrm{p}}=$ landings by pair trawlers in tonnes.
This shows a big increase in effort, by the pair trawler fleet, in 1996 and a small increase in the catch per unit effort over the previous year. (Table 5.2.3).

### 5.2.3 Weight at age and stock composition

The catch in numbers at age for the period 1970 to 1996 is given in Table 5.2.4. In 1995 the catch of 2 ringers was the highest since 1989 which suggested an improved recruitment of the 1993 year class. The indication from the 1996 catches is that this year class is good with the highest number of 3 ringers in the catch since 1989. The 1991 year class, which appeared to be above average in 1993 and 1994 but not in 1995, has again appeared in the
catches as a good year class in 1996. It is still not possible to tell whether these improved year classes come from either the spring spawning or autumn spawning components.

Weights at age are given in Table 5.2.5. Mean weights in the stock have not been available from research vessel surveys since 1991, therefore the weights in the stock used are the weights at age in the catches. Weights at age in previous years are as used by the Working Group in 1994.

Once again no attempt has been made to apportion catches between spring and autumn-spawning stocks for 1996 . The landings data show that the Scottish fishery was earlier this year and therefore not necessarily directed at aggregations of autumn-spawning fish as in 1995. Only the Northern Ireland vessels made significant landings ( 55 t ) in the autumn. The small landings in the first half of the year ( 12 t ) are mainly taken as by-catch in the demersal trawl fishery.

### 5.2.4 Surveys

No demersal egg surveys on the Ballantrae Bank and Brown Head spawning sites, no acoustic surveys in the Clyde and no spring trawl surveys were carried out in 1996. Historical estimates from these surveys are tabulated in (ICES 1995 Assess:13).

### 5.2.5 Stock Assessment

The structure of the stock in the Clyde remains uncertain. No survey data are available from recent years therefore no analytical assessment could be attempted.

### 5.2.6 Stock and catch projections

In the absence of an analytical assessment no stock projections can be provided.

### 5.2.7 Management considerations

The management of this fishery is made difficult by the presence of a mixture of a severely depleted springspawning component and autumn spawners from Division VIa south. The management objectives for these two components are necessarily distinct. The absence of fishery independent data from surveys further compounds the problem.

Historically the spring spawning stock supported a fishery with catches up to 15,000 tonnes per year in the 1960's. Landings generally began to decline through the 1970's and 1980's with a rapid decline in effort during the late 1980's up to the present time. A TAC was first set in 1984 ( $3,000 \mathrm{t}$.) increasing to a maximum of 3,500 tonnes in 1987 subsequently decreasing to 1,000 tonnes by 1993. Estimated catches, including discards, exceeded the TAC for the first four years. This was followed by a decline in catches to 1990. In 1991 there was a dramatic drop in both landings and effort and since then landings have fluctuated at below 1,000 tonnes. In 1996 the effort remained at a low level but there was a marked increase in catch per unit effort in the Scottish pair trawl fleet.

In the absence of surveys and no stock separation of the catches, nothing is currently known about the state of the spring spawning stock or the origins of the improved year classes of 1991 and 1993. All the management measures, currently in force, need to remain. Catches should be reduced to as low a level as possible and an attempt should be made to apportion those catches to spring and autumn spawning components.

### 5.2.8 Future research requirements

Provision of some fishery independent survey data for this area is necessary before an analytical assessment of the stock can be attempted. In a similar, but smaller stock, in the Thames estuary, a single pelagic trawl survey each year provides an index of recruitment and a measure of the mixture of spring and autumn spawners in the area. That survey now provides a ten year time series and together with landings data and biological sampling is sufficient for an analytical assessment of the state of this stock.

Further research is required to improve the understanding of the stock structure in the Clyde and in particular to attempt to apportion landings to spring and autumn spawners. If current management advice is required for the
spring spawning stock, the otolith structure technique, described by Mosegaard (WD,1996) for separating springspawners from autumn spawners in the Baltic, should be investigated.

There is evidence in adjacent stocks in Divisions VIa (North) and VIa (South) that there is a general increase in the spring spawning components of these stocks. Further research would be necessary to verify this in the Clyde.

Table 5.1.1. HERRING in Division VIa (North). Catch in tonnes by country, 1981-1995. These figures do not in all cases correspond to the official statistics and cannot be used for management purposes.

Table 5.2.5 HERRING in the Firth of Clyde. Mean weights at age in the catch and stock (g).

Figures 5.1.1 and 5.1.2 shows the influence of the use of four main combinations of data and model on the reference $F_{(3-6)}$ and on the SSB with reference to the baseline assessment (4).

1 shows the influence of the removal of a single outlying year (1993) from the acoustic time series, the results are indistingushable from line 4. 2 shows the results of excluding the limited age data on the shelf edge fishery and replacing it with Scottish age and mean weight at age data. 3 shows the influence of allowing a gradual change in the seprable constraint, this results in unreasonable recruitment to 1 ring herring. 4 is the final baseline assessment using all the age and mean weight data with a seperable constraint of 6 years

### 6.1 The fishery

### 6.1.1 Advice and management applicable to 1996 and 1997

The TAC for this area for 1996 was $28,000 \mathrm{t}$. This was a precautionary TAC and was the same as that set each year since 1992. The total catch estimated by the Working Group to have been taken from the stock during 1996 was approximately $32,500 \mathrm{t}$. This was approximately $4,000 \mathrm{t}$ higher than that recorded for 1995 and at about the same level as that from 1992-1995.There is considerable misreporting of catches in this area and the total catch recorded from the area is considerably lower than the actual catch taken from the stock.

Recent Working Groups have not carried out any analytical assessments for this stock but have suggested that the stock has declined in recent years and that the state of the stock is not known. The 1996 Working Group stated that, because of the extremely high catching power of the pelagic fleet in this area and because of it's ability to quickly change their target species, a cautious management should be adopted for this fishery. Therefore it was concluded that catches should not be allowed to rise above the 1995 level until more information on the stock became available. ACFM, in 1996, in the absence of an assessment, did not carry out a forecast for the stock but advised that a precautionary TAC, if required, should be set at a level so that the resulting catches did not exceed $25,000 \mathrm{t}$. The subsequent TAC agreed by the EU for 1996 was again set at $28,000 \mathrm{t}$.

### 6.1.2 Catch data

The main landings in 1996 from this fishery were again taken by Ireland who took over $95 \%$ of the total allocated catches. (Table 6.1.1.)

The total amount of unallocated catches in 1996 was over $8,600 \mathrm{t}$ which was considerably higher than that recorded for 1995. This unallocated catch is mainly composed of catches which were made in Division VIa (South) but which were reported as having been taken in Division VIa (North )) The total international catches, from Sub-areas VI and VII per statistical rectangle, based on log book data, and not corrected for "misreporting" are shown in Figures 4.2.1 a-d.

The catches and landings taken by each country fishing in this area from 1987-1996 are shown in Table 6.1.1 and the total catches from 1970 are shown in Figure 6.1.1. There were no estimates of discards reported from 1996 and there are no indications that discarding is a major problem in this fishery even though substantial catches from this fishery in recent years have been taken in a "roe" fishery. Reports, however, have been received of quantities of discarded herring taken by bottom trawlers fishing in the areas adjacent to known spawning grounds but it has not been possible to quantify the amounts.

The catches for 1996 are preliminary. It has not been found necessary to make any alterations to the 1995 data.

### 6.1.3 The fishery in 1996

Reports from the Irish fishery throughout most of 1996 as in 1995 suggested that herring shoals were very scarce, particularly in Division VIIb. As has been the pattern in recent years catches from the first quarter taken from Division VIa(South) contained substantial amounts of full and spawning fish. In 1996 these fish amounted to over $90 \%$ of the total catch in the first quarter and had a typical winter/spring vertebral count of 56.87 , compared with a vertebral count of 56.51 for full and spawning fish during Quarter 4. Recent Herring Working Groups have commented on the increasing numbers of winter/spring spawning fish which have appeared in the catches from this area in recent years and this pattern has been maintained in the early part of 1997. Herring shoals again appeared to be very scarce on the traditional autumn spawning grounds in Division VIIb in 1996. The main landings by the Irish fleet were taken during Quarter 4. Landings in this quarter increased in 1996 because of additional effort in the fishery due to the participation of the large pelagic trawlers who changed from fishing for mackerel and horsemackerel to fishing for herring.

Landings by the Irish fleet in 1996 were again regulated by weekly quotas and a closed season was introduced during June and July. This closed season is designed to prevent landings of herrings at a time when marketing difficulties are usually experienced.

### 6.1.4 Catch in numbers at age

The catches at age for this fishery since 1970 are shown in Table 6.1.2. In recent years the catches in numbers at age are derived mainly from Irish sampling data. The catches during 1996 were mainly dominated by 3 w.ring fish i.e.the 1992 year class which constituted over $38 \%$ of the total number. This year class was well represented in all areas. Older herring, mainly from the very strong 1985 year class, were taken in Quarter 3 in Div.VIIb where they constituted $28 \%$ of the total number.

### 6.1.5 Quality of the catch and biological data

Management authorities are confident about the accuracy of catch statistics from this area. However there may still be some under-reporting although , the extent of this cannot be quantified. Since 1994 the scarcity of herring throughout the year has not put pressure on skippers to under-report to any great extent. Misreporting of substantial catches taken in Division VIa (North) to the adjoining Division VIa (South) continued in 1996 but it was possible to re-allocate these catches based on information from fishermen.

The numbers of samples and the biological data, together with the length distribution of the catches taken per quarter by the Irish fleet, are shown in Tables 6.1.3 and 6.1.4 respectively. Sampling of catches throughout 1996 improved on the 1995 level and was considered satisfactory.

### 6.2 Mean Weights at Age

The mean weights (g) at age in the catches in 1996 are based mainly on Irish samples, together with one Dutch sample. The mean weights from 1970-1996 are shown in Table 6.2.1. The mean weights have increased in recent years because of the increasing amount of catches of full fish taken during the first quarter.

The 1996 mean weights at age for the stock at spawning time (1 October) are based on Irish samples of full fish taken during the fourth Quarter. The mean weights from 1970-1996 are shown in Table 6.2.2. and have been very similar in recent years.

### 6.3 Ground fish Surveys

Ground fish surveys have been carried out during November along the west coast of Ireland from 1993 to 1996. Over 60 stations have been sampled each year with a bottom trawl fitted with fine mesh liner. Although these surveys are designed to obtain an abundance index for demersal fish it is hoped that they will also provide recruitment indices for herring. The series, however, has not yet been established long enough to provide useful information.

### 6.4 Acoustic surveys

Acoustic surveys were initiated in this area in 1994, and are designed to provide an estimate of the total stock size. The third survey, again using the R.V. Lough Foyle, was carried out in July 1996 and covered the same areas as those in previous years. The results were presented in a working paper (Molloy and Fernandes, 1997. W.D.) and were also included in the report of the 1997 Co-ordinated Acoustic Survey (Simmonds et al., 1997 W.D.).

Considerable difficulties were experienced with the acoustic equipment throughout the 1996 survey. These difficulties were associated with the calibration equipment, the transducer cable and unidentified faults in the E.K.500. Despite intensive investigations it was not possible to identify the reasons for the very low SA values recorded during the survey which resulted in a very low estimate of stock size. The total stock sizes estimated in 1996 were unrealisticand were not used as a basis for any assessment. The total stock estimated for 1995 and 1996 were $354,000 \mathrm{t}$ and $135,000 \mathrm{t}$ respectively.

It is important, however, that acoustic surveys should be continued in this area because there is at present no other method of assessing the stock size and no basis for providing accurate management advice. Herring fisheries are extremely important to the local communities along the Irish coast and there is an extremely high catching capacity of the fleet in the area. The stock appears to have seriously declined in recent years and catches may need to be substantially reduced. Consideration should be given to changing the timing of the surveys in the area because of the difficulties in locating concentrations during the summer. The increasing importance of the
winter/spring herring in the area would suggest that acoustic surveys should be carried out during the winter in the southern part of Division VIa (South).

### 6.5 State of the Stock

Analytical assessments have not been carried out on this stock for a number of years because of the absence of survey data. Recent Working Groups have therefore only carried out VPA analyses to study the development of the stock and no stock projections have been made. The results of those analyses have indicated that the stock has decreased in recent years from a high level in 1988. This high level was as a result of the recruitment of the exceptionally strong 1985 year class which dominated the catches in this area for a long period.

The only additional data available to the present Working Group are the indications of a low stock size from the 1996 acoustic survey and reports from fishermen, both of which indicate a serious decline in stock size. In an attempt to demonstrate possible rates of decline it was again decided to run a series of VPAs with different input F values as has been done by recent working groups. A separable VPA was therefore carried out using the updated catch data and a terminal $S$ value of 1.0 and down weighted prior to 1990 to 0.001 . Age 4 was taken as reference age and the resultant exploitation pattern appears to be reasonably flat topped. The results of the separable VPA are shown in Table 6.5.1. The terminal populations from the separable VPA were then used to carry out traditional VPAs using input $F$ values $=0.3,0.4,0.5$ and 0.6 .

The results from the traditional VPA using F in 1996=0.6 are shown in Tables 6.5.2 and 6.5.3. These indicate that over the period 1970-1996 the spawning stock was at its maximum level in 1988 and has since declined steadily each year. The estimated SSB levels, obtained from using the different F values in 1996 are shown in Figure 6.5.1. The present SSB level is between $14 \%$ and $25 \%$ of the level in 1998 and may be between 50,000 t and $105,000 t$ depending on the input $F$ level. The recruitment of the exceptionally strong 1985 year class had a dramatic effect on the spawning stock in 1988. Since 1985 there have been no other outstanding year classes but there were indications in 1996 that the 1992 year class may have been above average size This, however has not been confirmed.

### 6.6 Stock Forecasts and Catch Predictions

As there is no method of obtaining a recruitment index for this stock and no estimates of stock size from survey data it has not been possible to carry out any stock forecasts or catch predictions.

### 6.7 Management Considerations

The results of these non analytical assessments indicate that the spawning stock has declined considerably in recent years and is now at a comparatively low level. This is consistent with observations from fishermen who in recent years have expressed alarm at the scarcity of herring in this area. There has been no substantial recruitment to the stock in recent years and the very strong 1985 year class has now reached the end of it's natural lifespan. The scarcity of herring may be due to a combination of the decline in stock accentuated by a more northerly distribution of the stock in recent years. It is also interesting to note the increasing importance of winter/spring spawning fish in this area. The old traditional fisheries in this area, which were extremely important in the early part of the century, were all based on winter/spring spawning herring.

As no analytical assessments have been carried out on this stock in recent years the TACs have been set on the average catch level recorded for Divisions VIa (South) and VIIb. The actual catch taken from the stock has consistently exceeded these recommended TACs because of the amounts taken in this area but misreported to Division VIa (North). Because of the decline in the stock and the importance of the fishery to the local communities serious attempts should be made to bring about an actual substantial and realistic decrease in the total catches. Until such time as it is possible to make an improved assessment of the stock and there is evidence of improved recruitment the catches should be stabilised at a level considerably below those recorded in recent years.

### 6.8 Medium Term Projections and Consideration of MBAL

Medium term projections and the MBAL for this stock were considered by the 1996 working group but it was not possible to carry out any projections because of the absence of sufficient data. The situation has not altered in 1997 and in the absence of information about current recruitment levels and because of the uncertainty about the
current stock size no projections were carried out. An examination of the spawning stock/recruitment relationship (Figure 6.8.1) suggests that there is little evidence of any relationship between spawning stock and recruitment over the range of SSB and recruitment encountered.

An examination of the historical data series (1970-1995) did not suggest any period when the stock was subjected to a low fishing effort i.e F below 0.1. The lowest F values were recorded during the period 1984 to 1986 when the mean F was about 0.21 and the average $\operatorname{SSB}$ was about $180,000 \mathrm{t}$. At that time the average catches were about $26,500 \mathrm{t}$. Therefore it might be suggested that if the stock was at this level the fishery might then be able to sustain catches of about $26,000 \mathrm{t}$. The present analyses suggests that the spawning stock has seriously declined in recent years and, even though the exact size is not known, it would appear to be well below $180,000 \mathrm{t}$. This in turn would suggest that the present catches are far too high. It has not been possible with the present data to calculate the MBAL for this stock.

Table 6.1.1 Estimated Herring catches in tonnes in Divisions VIa (South) and VIIb,c, 19861996. These figures do not in all cases correspond to the official statistics and cannot be used for management purposes.

Table 6.5.1

Title : Herring Via South (run: SEPJM24/S24)
At 15-Mar-97 15:51:28

## Separable analysis

from 1970 to 1996 on ages 0 to 8
with Terminal $F$ of .600 on age 4 and Terminal $S$ of 1.000
Initial sum of squared residuals was 2910.224 and
final sum of squared residuals is 1235.700 after 150 iterations

## 7 IRISH SEA HERRING (DIVISION VIIA, NORTH)

### 7.1 The Fishery

### 7.1.1 Advice and management applicable to 1996 and 1997

In 1995 no analytical assessment of this stock was undertaken due to continued uncertainty about the fishing mortality and level of SSB. ACFM concluded that the present state of the stock was not known. Consequently the ACFM advice was that if a precautionary TAC is required for 1995 it should not exceed the recent catch levels of $5,000 \mathrm{t}$. A TAC of $7,000 \mathrm{t}$ was subsequently adopted for 1996 and partitioned as $1,820 \mathrm{t}$ to Ireland and $5,180 \mathrm{t}$ to the UK.

In 1996 the UK fishery opened in the third week in June. The Irish fishery opened in the second week of August with one pair of vessels taking a small catch in September, and took no further participation in this fishery. Closed areas for herring fishing in the Irish Sea along the east coast of Ireland and within 12 nautical miles of the west coast of Britain were maintained throughout the year. The Mourne gillnet fishery, which has a derogation to fish within the Irish closed box, opened in September and closed in November. The area to the east of the Isle of Man (encompassing the Douglas Bank spawning ground) was closed from 21 September to 31 December.

In 1996 an analytical assessment was undertaken and ACFM concluded that the stock was within safe biological limits although the precision of the scientific assessment was comparatively low due to the short time series of catch-independent data. ACFM suggested that continued exploitation at $7,000 \mathrm{t}$ would not be detrimental to the stock. A TAC of 9,000 t was adopted for 1997 and partitioned as $2,340 \mathrm{t}$ to the Republic of Ireland and $6,660 \mathrm{t}$ to the UK.

### 7.1.2 The fishery in 1996

The catches reported from each country, for the period 1983 to 1996 are given in Table 7.1.1 and from 1972 to 1996 in Figure 7.1.2. Again there has been no estimate of discarding or slipping. The total catch of 5,302t was again below the recommended TAC of $7,000 \mathrm{t}$. As in 1993 to 1995, this was mainly due to the Republic of Ireland not taking substantial quantities of herring from Division VIIa(N). In 1996, 59\% of the total catch was taken in the 3rd quarter. There did not appear to be any landings from the Mourne gillnet fishery.

### 7.1.3 Quality of catch and biological data

There are still no estimates of discarding or slippage of herring in the Irish Sea fisheries. Landing statistics are assumed to be accurate.

Biological sampling in this fishery remains fairly high with approximately one sample per 100 t landed (Table 7.1.2). However, there were no samples taken in the 1st, 2nd and 4th quarters; this meant that $1,246 \mathrm{t}$ (approximately $24 \%$ ) landed were not sampled and third quarter biological data needed to be applied to these catches.

### 7.1.4 Catch in number at age

Catches in numbers at age are given in Table 7.1 .3 for the years 1972 to 1996. The predominant year class in 1996 was the 2 -ringers (1993 year class). The 1992 year class, which was numerically the most abundant year class in the 1995 catches was still abundant in the 1996 catches. The 1990 year class was also still abundant. The catch in numbers at length is given in Table 7.1.4 for 1988 to 1996 . Over this time period there has been a slight reduction of lengths of the predominant numbers of fish in the catches. The distribution of lengths in 1996 was similar to that in the preceding years with a low abundance of fish over 30 cm compared with 1988 and 1989, during which the strong 1979 and 1980 year classes were abundant in the catches (see Table 7.1.3).

### 7.2 Mean length, weight, maturity and natural mortality at age

Mean lengths at age were calculated for the 3rd quarter using the Northern Ireland data and are given for the years 1985 to 1996 in Table 7.2.1. In general, mean lengths at age have remained fairly stable since 1988.

Mean weights at age in the stock are given in Table 7.2.2. Mean weights at age in 1996 were, in general, comparable to the mean weights in 1995. Mean weights at age in the third-quarter catches have been used as estimates of stock weights at spawning time.

The maturity ogive used in 1994 (ICES 1994/ Assess:13) was used again since there was no evidence to suggest a change: 0.08 for 1 -ringers, 0.85 for 2-ringers and 1.00 for 3+-ringers.

As in previous years, natural mortality per year was assumed to be 1.0 on 1-ringers, 0.3 on 2-ringers, 0.2 on 3ringers and 0.1 on all older age classes.

### 7.3 Research surveys

### 7.3.1 Acoustic surveys

The information on the time series of acoustic surveys in the Irish Sea is given in Table 7.3.1. No acoustic survey was undertaken on Douglas Bank in 1996 as a result of equipment failure and poor weather conditions.

An acoustic survey was undertaken over the whole northern Irish Sea (Division VIIa(N)) between 2 and 12 September 1996 by Northern Ireland as part of a time series that commenced in 1994. The survey is described in detail by Armstrong and Burns (WD 1997). The survey was carried out using a Simrad EK500 echosounder with a towed 38 kHz split-beam transducer. The survey was stratified to allow variable sampling intensity according to the expected distribution of herring. Targets were identified where possible by midwater trawling. The general spatial distribution of pelagic fish targets in 1996 was similar to that observed in 1994 and 1995, although more adult fish were found over the Douglas Bank spawning ground (Figure 7.3.1). Herring classified as 0 ringers were most abundant off the NW of the Isle of Man, the Solway Firth and the Irish coast. Herring classified as 1 ringers were scarce in the trawl catches. No fish aggregations were found in Liverpool Bay and off the North Wales coast.

In 1994 and 1995 the estimates of biomass were given as fish 1 -ring and older. The biomass recorded was adjusted by a factor of 0.6 (the mean proportion of SSB to $1+$ fish) to obtain an estimate of SSB. The estimates of biomass from 1994, 1995 and 1996 were re-analysed (Armstrong \& Burns WD 1997) using age length keys and mean weight at age from fish sampled in each survey, to give a survey specific 1-ringer and older to SSB ratio (Table 7.3.1). As a result, the SSB estimates for 1994 and 1995 have been increased, and the large number of 1 -ringers in the 1995 survey, compared to 1994 and 1996, taken into account.

A further acoustic survey (using a Simrad EK500 echosounder with a towed 120 kHz split-beam transducer) was carried out in the closed box along the English and Welsh coast in December 1996 (Armstrong WD 1997) to investigate the winter distribution of adult and juvenile herring.

### 7.3.2 Larvae surveys

Larvae surveys were undertaken by Northern Ireland (whole of Division VIIa(N)) and the Isle of Man (northeastern Irish Sea). Due to poor weather, no survey took place on the Douglas Bank and both the north-eastern Irish Sea survey and the VIIa (N) survey were much reduced. The north-eastern Irish Sea survey (the 4th in the series) was undertaken on the 26 November 1996 (see Nash \& Hughes WD 1997). The numbers of larvae at 6 mm length and the estimated larval production were the lowest on record (Table 7.3.2). The distribution of spawning dates, back-calculated from the length at capture, suggested that the majority of the larvae were spawned between 22-30 October 1996.

The 4th Northern Irish larvae survey of Division VIIa(N) was undertaken between 17 and 20 November 1996 (Dickey-Collas WD 1997). The poor weather resulted in only 7 stations being sampled in the western Irish Sea. As in 1995, no Mourne larvae were caught. Manx larvae were distributed across the north east of the Irish Sea, in a similar pattern to other years. Using the larval lengths, spawning was estimated to be in the last 3 weeks of October, a similar estimate to the north-eastern Irish Sea survey. The estimate of total larval production in 1996 $\left(3.9 \times 10^{11}\right)$ was much lower than in previous years (Table 7.3.2). Both the Douglas Bank larval survey and the Division $\mathrm{VII}(\mathrm{N})$ survey show similar interannual variations in estimated larval production (Table 7.3.2).

### 7.3.3 Groundfish surveys of Area VIIa(N).

Groundfish surveys, carried out by Northern Ireland since 1991 in the western Irish Sea, were used by the 1996 Herring Assessment Working Group to obtain indices for 0 group and 1 -ringer herring in the Irish Sea. They indicated a strong 1992 year class. These data have since been re-analysed to cover the whole Irish Sea (Figure 7.3.2) and combined with new 1996 data (Burns \& Armstrong WD 1997). The strong 1992 year class is still evident although the large 1990 year class found in the catch at age data is not apparent (Table 7.4.1).

### 7.4 Data exploration and preliminary modelling

In 1996 an analytical assessment of this stock was undertaken. Western Irish Sea groundfish indices for 1-ringers, acoustic estimates of SSB and Douglas Bank larvae indices of SSB were used as tuning files. This year all the groundfish indices were reworked to reflect the whole Irish Sea (see section 7.3.3) rather than just the western Irish Sea and the acoustic estimates were corrected to reflect the true estimates of SSB (see section 7.3.1). This year, the survey indices were used to initiate an analytical assessment using an integrated catch-at-age analysis (ICA) including a separable constraint (Deriso et al. 1985). The Integrated Catch Analysis (ICA) (see section 1.5) was used. The following short survey series were available for inclusion in an assessment using the ICA package:

1. Larval production estimates from Douglas Bank surveys to provide an SSB index: 1989-1995 (DBL)
2. Larval production estimates from Douglas Bank surveys to provide a recruitment index: 1989-1995 (LPER1)
3. Age-aggregated acoustic estimates of Manx herring spawning aggregations in 1989, 1990 and 1994 (AC_DB)
4. Age-aggregated acoustic estimates for the SSB of herring in Division VIIa(N) in September 1994-1996 (AC_VIIa(N))
5. Age-disaggregated acoustic estimates for the SSB of herring in Division VIIa(N) in September 1994-1996 (ACAGE)
6. Irish Sea groundfish survey indices of 0-ring herring in September 1991-1996 (GFS0S)
7. Irish Sea groundfish survey indices of 1-ring herring in March 1992-1996 (GFS1M)
8. Irish Sea groundfish survey indices of 1-ring herring in June 1991-1994 (GFS1J)
9. Irish Sea groundfish survey indices of 1-ring herring in September 1991-1996 (GFS1S)

The different indices are given in Tables 7.4.1 and 7.4.2. As in this stock 1-ringers are used as the youngest age class the data for O-ringers in the September groundfish surveys (Table 7.4.1) have been assigned to the year that they will be used as a 1 -ringer index. Although individual CVs of the GFS series were comparatively high, similar overall trends were apparent in the four series, with the 1992 year class being strongest in each series. Larval production on the Douglas Bank was also high in 1992. In 1996 it was decided to treat this series as SSB indices in accordance with practices for other herring stocks, however, this year they were also examined as recruitment indices.

The ICA model was fitted using each series in turn (the acoustic survey data were analysed together (SSBA) because of the shortness of the AC_DB and AC_VIIa(N) series). The following input values were used:

- Separable constraint over last 6 years (weighting $=1.0$ for each year)
- Reference age $=4$
- Constant selection pattern model
- Selectivity on oldest age $=1.0$
- First age for calculation of reference age $=2$
- Last age for calculation of reference age $=6$
- Weighting on 1-ringers $=0.1$; all other age classes $=1.0$
- Weighting for all years $=1.0$
- All indices treated as linear
- No S/R relationship fitted
- Lowest and highest feasible $\mathrm{F}=0.05$ and 1.0
- All survey weights fitted by hand i.e. 1.0
- Correlated errors assumed i.e. $=1.0$
- No shrinkage applied

It was again decided not to treat the Division VIIa(N) acoustic survey estimates as absolute because of discrepancies between acoustic estimates and tuned SSB estimates seen in other stocks. No solution could be found using series GFS1M, GFS1J and GFS1S. There was a solution with the GFS0S series but this gave an unacceptably high reference $\mathrm{F}(15.46)$ and was not used. The failure of the GFS data to provide good indices could be because they only provide 1 ringer indices and it is known that Celtic Sea juveniles do occur in Division $\mathrm{VIIa}(\mathrm{N})$. Estimates of $\mathrm{F}(96)$ for the reference age class 4 from the other tuning series are shown in Figure 7.4.1 together with $\pm 1 \mathrm{SD}$ intervals. Mean values ranged from $<0.1$ to 0.30 . Precision was generally poor. In an attempt to explore the performance of these tuning indices the LPER1 was combined with ACAGE and LPER1 with SSBA. Both are also given in Figure 7.4.1. In view of the limited data available and the variability in perceptions of reference $F$ it was decided to only present the ranges in $F$ over the time series and variability in perceived SSB for this range of terminal Fs.

### 7.5 Stock assessment

The variation in $\mathrm{F}(2-6)$ generated from using the various tuning indices is given in Figure 7.5.1. It is obvious that the Douglas Bank larvae survey (DBL) presents questionably low levels of fishing mortality. All other tuning indices show variation in fishing mortality after 1985 with a generally slow decrease over the years. This is consistent with the reported landings remaining relatively stable at approximately $5,000 \mathrm{t}$ from 1991 to the present.

The consequences of these variations in fishing mortality on SSB are shown in Figure 7.5.2. The range in SSB for 1996, from the tuning indices (excluding DBL(SSB)), is between 11,000 and $44,000 \mathrm{t}$. The lowest estimate came from using the acoustic data as age disaggregated indices, primarily for age structure in the population. The highest estimate came from using the acoustic series as SSB indices.

The assessment in 1996 suggested an SSB in 1995 of $38,000 \mathrm{t}$, which is not dissimilar to the estimate of SSB for 1995 this year (approximately $33,000 \mathrm{t}$ ) from the acoustic SSB tuning indices (SSBA). However, three of the tuning series used in 1996 were not used this year (GFS1M, GFS1S and DBL) and one was converted from SSB indices to recruitment indices (LPER1). Unfortunately, there is no objective way to determine which tuning series or combination of tuning series will provide the most likely SSB in the current year since in most cases the series are short and in many cases they are noisy.

Therefore, the Working Group decided not to undertake an analytical assessment of herring in Division VIIa(N) this year.

### 7.6 Stock and Catch Projection

No short-term predictions were undertaken for this stock due to the uncertainty of the size of the SSB. The Working Group noted that the TAC for 1997 has been raised from 7,000 to $9,000 \mathrm{t}$. In the recent past the Irish fleet has not taken substantial catches from Division VIIa(N) but the UK has recorded landings close to its quota. There is no reason to suspect this will not happen in 1997 with the increased quota. Therefore, it is anticipated that landings in 1997 will increase from approximately 5,000 to at least $6,500 \mathrm{t}$. The consequences of this on levels of SSB are, at present, unknown.

### 7.7 MBAL, limit and target reference points

In 1996 (ICES 1996/Assess: 10) an attempt was made to estimate MBAL for this stock. The conclusion was that $20,000 \mathrm{t}$ was a sensible level for this stock. However, the Working Group stated that further analyses should be done to verify a reasonable level for MBAL. In light of the present analyses the level of MBAL will need to be re-examined once the level of SSB in $\operatorname{VIIa}(\mathrm{N})$ has been determined with an appropriate degree of certainty.

In regard to $\mathrm{F}_{\mathrm{lim}}$ and target Fs , again due to uncertainties in an assessment of this stock neither can be calculated with any precision.

### 7.8 Medium-term predictions of stock size

Due to uncertainties in present fishing mortalities and SSB, medium-term predictions were not undertaken.

### 7.9 Management considerations

### 7.9.1 Precision of the assessment

The current time-series of survey data are very short and, as seen here, prone to providing variable perceptions of stock development. Assessments will be possible with longer time-series of abundance indices, especially from acoustic and larvae surveys which are now established in the area.

All indices show an increase in SSB from 1994 to the present, the degree of increase is uncertain. The perceived increase in SSB is primarily due to three relatively strong year classes (1990, 1992 and 1994) within the population. Therefore, maintaining the present catch level, in the short-term, of approximately $5,000 \mathrm{t}$ should not be detrimental to the stock. The consequences of catches above $5,000 \mathrm{t}$ on SSB are at present unknown.

### 7.9.2 Spawning and Juvenile Fishing Area Closures

The present arrangement of closed boxes in Division VIIa $(\mathrm{N})$ are discussed in detail in ICES (1996/Assess: 10). The closed areas consist of: all year juvenile closures along the east coast of Ireland, and the west coast of Scotland, England and Wales; spawning closures along the east coast of the Isle of Man, and along the east coast of Ireland.

In view of the uncertainties in the size of the stock in Division VIIa(N) the Working Group recommends that any alterations to the present closures are considered carefully, in the context of this report, to ensure protection for all components of this stock.

### 8.1 The Fishery

### 8.1.1 ACFM advice applicable for 1996 and 1997

No ACFM advice on sprat TAC has been given in recent years. The TAC set by the management bodies was $175,000 \mathrm{t}$ for 1995 [Subarea IV(EU zone) + Division IIa (EU zone)] and 200,000 t for 1996. The agreed TAC for 1997 is $150,000 \mathrm{t}$

### 8.1.2 Catches in 1996

Landing statistics for sprat for the North Sea by area and country are presented in Table 8.1.1 for 1983-1996. As in previous years, sprat from the fjords of western Norway were not included in the landings for the North Sea. Landings from the fjords are presented separately because the uncertainty concerning their stock identity. Norwegian catches in the western fjords for 1983-1996, are presented in Table 8.1.2.

The monthly and annual distributions of catches by rectangle for Sub-area IV are shown in Figures 8.1.1-8.1.13. The catches reported in the rectangles 41F3-42F4 are unuasual and may be misreportings from other rectangles in Division IVb.

Landing figures for Denmark, Sweden, Norway and UK indicate that $136,600 \mathrm{t}$ sprat were harvested from the North Sea in 1996, which was a decline in landings of about $60 \%$ compared with 1995 . Nearly $60 \%$ of the landings were taken in January. After considerable increases in landings from about 10,000 $t$ in 1986 to a peak of $320,600 \mathrm{t}$ in 1995, the Danish landings decreased to $81,000 \mathrm{t}$ in 1996. During the last years, $60-70 \%$ of the Danish sprat landings have been reported from the third quarter. To reduce the herring by-catches in the smallmeshed fishery, Denmark banned sprat fishing from 1 July to 15 August. In 1996 the Danish landings in third quarter made up for less than $10 \%$ of their landings. The Norwegian landings were $53,000 \mathrm{t}$, the highest recorded for the period. UK catches continued to be at a very low level. Catches by Norway in the western fjords were at the same level as in 1995 with $3,300 \mathrm{t}$.

Landings by area and quarter are shown in Table 8.1.3. Again, most of the landings were reported from Division IVb , predominantly Division IVbE. In 1996 landings from this division were mainly from the first (January) and fourth quarter (October-December).

### 8.1.3 Fleets

The sprat is mainly taken in a directed sprat purse seine fishery and in the fleet B fishery as defined in the North Sea herring assessment (see Section 2.10 and Section 2.15 ad 1.3 a ).

### 8.2 Catch Composition

### 8.2.1 Catches in number

Uncertainties in the reliability and/or absence of quarterly aged samples have prevented the IFWG and later the HAWG, from running a VPA since 1984. A historical perspective of the problems associated with estimates of catch in numbers at age by previous groups up to 1992, is described in the report of the Herring Working Group for 1993 (ICES 1993/Assess:15).

The estimated quarterly catch-at-age in numbers is presented in Table 8.2.1. Age composition data for commercial landings for 1996 were provided by Denmark and Norway. There is a difference in age composition in the Danish and the Norwegian landings in the first quarter. This might be a result of the different gears used in the two fisheries with the Danish using bottom trawl and the Norwegian purse seiners.

### 8.2.2 Mean Weight at age

The mean weights (g) at age in catches taken in 1994-1996 are presented by quarter in Table 8.2.2. Weights were estimated from Danish and Norwegian commercial data as provided by Working Group members.

### 8.2.3 Quality of catch and biological data

The sampling intensity for biological samples, i.e age and weight at age, is given in Table 8.2.3. The number of samples has improved but is still below the recommended level.

The sampling of Danish landings for industrial purposes continued with the intensity and coverage largely unchanged compared to the previous years. From the Danish landings 32 samples were used to estimate age composition and weight at age of sprat and 36 samples from the Norwegian landings. No sprat were reported in the landings from the Norwegian small meshed fishery targeted at sandeel and Norway pout. Sampling intensity for species compositions is presented in Section 2.15.

### 8.3 Recruitment

### 8.3.1 Abundance

The IBTS(February) sprat indices, no per hour, are used as an index of abundance. The historical data were revised by the Working Group in 1995 (ICES 1995/Asses:13). The IBTS-indices are presented in Table 8.3.1 for age groups 1-4, $5+$ and total, along with the number of rectangles sampled and the number of hauls considered.

Table 8.3.1 indicates an increase in the 1 -group index, but the index is still below the average of 1 -group index 1981-1996. It also indicates a strong decrease in the 3-group. The 1993-year class which was observed to be strong as 3 -group in 1996, were in 1997 at a level normal for the 4 -group. The total 1997-abundance index increased from 1996 but was below the values for 1992-1995.

The IBTS data are provided by rectangle in Figure 8.3.1 for age groups 1, 2 and 3+. Age 1-group were found to be concentrated in the central-eastern areas of Division IVb and IVc. The mean lengths in mm of age-group 1 by rectangle are presented in Figure. 8.3.2.

### 8.4 Acoustic Survey

Sprat abundance was estimated from the ICES Coordinated Herring Acoustic survey in June-July 1996 (WD Simmonds et al, 1997b). The sprat were mainly found in the western North Sea, west of $2^{\circ}$ E. The survey area coverage in the eastern and central part of Sub-division IVb does not include the whole area where sprat normally is distributed. Total stock estimates by number and biomass were:

|  | Numbers <br> (mill) | Biomass <br> ('000 t) |
| :--- | :--- | :--- |
| 1996 | 20042 | 213 |

In the western area, unfortunately, weights of the sprat samples were not properly taken during the survey. The mean weight per size-class was derived from sprat taken during the IBTS-survey in January and February 1997. Samples for ageing were either not available or there were some difficulties in interpreting the otoliths.

### 8.5 State of the Stock

### 8.5.1 Catch-Survey Data Analysis

The IBTS surveys have difficulties following strong and weak cohorts for sprat, which has also been demonstrated by the last years Working Groups (see 1996). The 1-group:2-group ratio varies among 0.32 (1981 year class) and 7.57 (1988 year class).

Combined with the ageing problems, this implies that the available indices do not adequately reflect the dynamics of the stock.

Prior to 1997 the data have not permitted projections of either catches or stock sizes. As discussed in the 1995 Herring Working Group report (ICES 1995/Asses:13), the 1989 IBTS index continues to be an outlier in a regression of total landings and IBTS-indices. The regression was also highly affected by the 1994 observation.

Regression of the total catches and the IBTS indices for 1981-1996 shows as in previous years the 1989 index to be an outlier and this value was deleted in the subsequent analysis. The 1997 (February) index was applied to a regression excluding the 1989 -index $\left(r^{2}=0.81\right)$ and this predicted a yield for 1997 of 110,000 tons, see Figure 8.6.1. Other regressions using log-log relationship gave similar prediction for 1997.

ACFM in May 1996 commented that "it is wrong to regress numbers on yield". The HAWG does not think it is wrong but of course that the slope has the dimension of tons per number. It may well be that the biomass IBTS index would be a worse predictor than the number index if the mean weight at age measured in February is a highly variable predictor of the mean weight at age at the time of the catch. The procedure was recommended by ACFM in 1993 in its comments to the assessment at that time.

An attempt to improve the analysis was performed by including a model for stock development, The Biomass dynamic model. This model was fitted using the CEDA program, see ICES (1993/Assess:15). The data were total catch and IBTS(February) abundance indices for 1978 to 1996. The initial state of the stock in 1978 was assumed to be that the biomass was 0.25 of the carrying capacity K . The 1989 observation was again considered as an outlier. A new run was done excluding the 1989 -index. The model suggests that the biomass is currently at a very low level, Figure 8.6.2a. The log residuals on the abundance IBTS indices are considerable,Figure 8.6.2b.

SHOT estimates (Shepherd, 1991) were provided by the IFWG, but as demonstrated in their report of 1992 (ICES 1992/Assess:9), little confidence was put in the estimates. At that time the analysis was driven by the very strong 1989-index. With more data available, the Herring Assessment Working Group decided to undertake a new SHOT-estimate for the North Sea sprat. The estimated landings for 1997 using the total IBTS-indices was found around 100000 tonnes, Table 8.6.1. Other runs using the 1-group indices and the combined 1-and 2-group indices gave similar estimates for the 1997 yield.

### 8.7 Management Considerations

The stock shows signs of heavy exploitation as both catch and biomass appear to be decreasing. There is no signs of a good year class recruiting to the 1997 fishery. Therefore, catches should be reduced to the lowest possible level until there are signs of increased recruitment.

### 8.8 Research Recommendations

The Working Group considered the research required to improve the quality of the sprat assessment and recommends the following to be addressed before the next meeting of the Working Group:

- Data from the acoustic survey in 1996 indicate that sprat abundance estimates can be obtained from this survey. The work deriving these estimates for 1995 and earlier years should be continued.
- The improvement of the biological sampling intensity in the last three years should be continued.

Table 8.1.1 Sprat catches in the North Sea (' 000 t ) 1983-1996. Catch in fjords of western Norway excluded (Data provided by Working Group members except where indicated). These figures do not in all cases correspond to the offical statistics and cannot be used for management purposes.

### 9.1 The fishery

### 9.1.1 ACFM advice applicable for 1997

The TAC for this fishery was set to 12000 t for 1997. No ACFM advice has been provided in recent years.

### 9.1.2 Catches in 1997

Table 9.1.1 shows the nominal landings in 1983-1997. The landings in 1997, as reported by UK(England\&Wales), were at the same low level as in the last years. Monthly catches for the Lyme Bay sprat fishery are shown in Table 9.1.2. Monthly and annual distributions of catches by rectangle are shown in Figures 8.1.1-8.1.13.

### 9.2 Catch Composition

Data on catch composition and mean weights were available for the Working Group for April, October and December (three samples). Catch compositions and the mean weights for 1991-1997 are given in Table 9.2.1 and Table 9.2.2.

Table 9.1.1 Nominal catch of sprat (t) in Divisions VIId,e, 1983-1996.

### 10.1 Fishery

### 10.1.1 ACFM advice applicable for 1996 and 1997

ACFM advice on a sprat TAC has not been provided in recent years. Sprat is landed under the TAC for the mixed clupeoid fishery, including all catches of all species taken in this fishery (see Section 2.15 a ).

The proportion of sprat in the mixed clupeoid fishery increased substantially between 1993 and 1994. In 1994 and in 1995 there was, for the first time in several years, a directed sprat fishery for industrial purposes in Skagerrak and the northern part of Kattegat. The high sprat catches were not seen in 1996. The TACs for this fishery, as adopted by the management bodies, were $43,000 \mathrm{t}$ in 1994, 1995 and 1996. The TAC set for 1997 was $40,000 \mathrm{t}$, with a restriction in by- catches of herring not to exceed $12,000 \mathrm{t}$.

### 10.1.2 Catches in 1996

The total annual landings for Division IIIa by area and country in 1974-1996 are given in Table 10.1.1. The Norwegian and Swedish catches include the coastal and the fjord fisheries. The total landings in 1996, as estimated by the Working Group, were $18,000 \mathrm{t}$. This was a reduction of nearly $70 \%$ from 1995. Decreases were reported in both the Danish and Swedish industrial landings. Of the total landings about $14 \%$ were taken for human consumption, $1,000 \mathrm{t}$ by Norway and $1,450 \mathrm{t}$ by Sweden, mainly in Skagerrak.

Landings by quarter for all three countries are shown in Table. 10.1.2. About $50 \%$ of the total landings were taken in the first quarter, and about $25 \%$ in each of the quarters 2 and 4 . Small landings were reported by the industrial fisheries in third quarter. There was a total ban on the directed Danish sprat fishery (mixed clupeoid) from 16 March to 30 September. The Norwegian landings for human consumption were taken in the third and fourth quarter, the Swedish mainly in the first quarter

The composition of sprat and herring in the mixed-clupeoid fishery in the last two years, are given in Table 10.1.3.

### 10.1.3 Fleet

The sprat fishery in Division IIIa is conducted by fleets from Denmark, Norway and Sweden. The Danish landings are taken by two fleet categories: 1) a directed sprat (mixed clupeoid) trawl fishery using minimum mesh size of 32 mm (see herring fleet $D$ defined in section 2.10) and 2) by catches from the small mesh ( 16 mm ) fisheries for Norway pout, blue whiting and sandeel. The landings are for reduction purposes.

The Swedish sprat fishery can be divided into three categories: 1) directed herring trawl fishery with minimum mesh size of 32 mm and by purse seines, mainly for human consumption (see herring fleet C defined in section 2.10 ), 2) directed sprat fishery for human consumption carried out by purse seines (see herring fleet D) and 3) a directed sprat (mixed clupeoid) trawl fishery with mainly 16,18 or 22 mm mesh size, for human consumption and for reduction purposes, (see herring fleet D).

The Norwegian sprat fishery in Division IIIa is an inshore purse seine fishery for human consumption.

### 10.2 Catch composition

### 10.2.1 Catches in number and weight at age

No weight-at-age data in the catches were available for 1983- 1991. For 1992-1993 data were supplied by Denmark, in 1994 and 1995 by Denmark and Sweden, and in 1996 only by Denmark.

The numbers and the mean weight by age in the industrial landings in 1992-1996 are presented in Tables 10.2.1 and Table 10.2.2, respectively. For 1996 the number by age group represents about $67 \%$ of the total industrial sprat landings in Div. IIIa. Low mean weight in age group $1(4,5 \mathrm{~g})$ in fourth quarter, indicate that there might be problems in the ageing.

### 10.2.2 Quality of catch and biological data

Denmark introduced an improved monitoring system for management and scientific purposes in 1996 (see Section 2.15). Samples used for estimation of sprat age and mean weight at age, were provided by Demark for the industrial/"mixed clupeoid" fisheries. The amount of sampling has improved and is considered as adequate. As in previous years, no samples of sprat were taken from the fisheries for human consumption. Details on the sampling for biological data are shown in Table 10.2.3.

### 10.3 Recruitment

### 10.3.1 Abundance of 1-group and older sprat from IBTS

The IBTS(February) indices for 1984-1995, were revised by the 1995 Herring Working Group (ICES 1995/Assess:13). The indices, calculated as mean cpue (no./hr) weighted by the area with water depths between 10 and 150 m of the rectangle, are presented in Table 10.3.1. The IBTS data are provided by rectangle in Figure 8.3.1 for age groups 1,2 and $3+$, and the mean length (mm) of 1-gr sprat in Figure 8.3.2.

The 1997 IBTS indices indicate a continuation of the reduction in the 2-group and 1-group index which is at the same low level as last year. The index of 3-group appears to be high, following a high 2-group index in 1996. The total 1997 sprat index for Division IIIa was one of the lowest recorded in the period 1984-1996.

The age structure of sprat from the survey is rather variable, with difficulties in following strong and weak cohorts from year to year. The ratio $1-\mathrm{gr} / 2-\mathrm{gr}$ has varied between 0.27 and 2.91 (see ICES 1996/Assess:10).

### 10.4 Acoustic Survey

Acoustic estimates of sprat were estimated from the ICES Coordinated Herring Acoustic survey in June-July 1996 (WD Simmonds et al. 1997b). The total number of sprat was $7.9 \times 10^{8}$ or 14,267 tonnes. The main densities of sprat were found in the inner area, with $95 \%$ of the biomass in Kattegat. The majority of the sprat were between 1 and 3 years old and 12 and 14 cm .

### 10.5 State of the Stock

No assessments of the sprat stock in Division IIIa have been presented since 1985 and this year is no exception. The Working Group concluded that the data available do not allow any assessment which could be helpful for management.

### 10.6 Projection of Catch and Stock

IBTS(February) index plotted vs the catch in the same year ( $\mathrm{r}^{2}=0.05$ ) is shown in Figure 10.6.1. The 1994 and 1995 observations are anomously high.

SHOT estimates (Shepherd, 1991) were provided by the IFWG, but as demonstrated in their report of 1992 (ICES 1992/Assess:9), little confidence was put in the estimates. With more data available, the Herring Assessment Working Group decided to undertake a new SHOT-estimate for the Div.IIIa sprat. The estimated landings for 1997 using the total IBTS-indices was found around 10,000 tonnes, Table 10.6.1. Other runs using the 1-group indices and the combined 1-and 2-group indices gave similar estimates for the 1997 yield.

### 10.7 Management Considerations

The recruitment between years does not appear to be driven directly by fishing effort. The sprat stock has in recent years been mainly fished together with herring, except from 1994 and 1995 when a directed sprat fishery was implemented. The human consumption fishery is only a minor part of the total catch. The natural variability in the stock is high.

### 10.8 Research Recommendations

The Working Group considered the research required to improve the quality of the sprat assessment and recommends the following to be addressed before the next meeting of the Working Group:

Data from the acoustic survey in 1996 indicate that sprat abundance estimates can be obtained from this survey. The work deriving these estimates for 1995 and earlier years should be continued.

The improvement of the biological sampling intensity in the last three years should be continued.

Table 10.1.1 Landings of SPRAT in Division IIIa Catch (in tonnes $10^{-3}$ ). (Data provided by Working Group members). These figures do not in all cases correspond to the official statistics and cannot be used for management purposes.
