1 TERMS OF REFERENCE

The Pandalus Assessment Working Group (WGPAND) (Chairman Mr. S. Tveite, Norway) will meet in Lysekil, Sweden from 9-12 September 1997 to:

- a) assess the status of the stocks of *Pandalus borealis* in the North Sea, Skagerrak and Kattegat and provide catch options for 1998;
- b) provide information on quantities of discards by gear type and area for the stocks of Pandalus and fisheries considered by this group (OSPAR 1997/5:3) and report to WGECO;
- c) determine the predation mortality of *Pandalus* stocks;
- d) continue the work on determining the criteria for ageing;
- e) continue the work on the definition of population and assessment units;
- f) report to the ACFM and the Shellfish Committee.

The above terms of reference are set up to provide ACFM with information required to respond to the requests for advice from NEAFC, the EC and OSPAR.

2 PARTICIPANTS

P. Koeller	Canada
S.A. Pedersen	Denmark
B. Sjöstrand	Sweden
S. Tveite (Chairman)	Norway

Data from Scottish and English shrimp fishery in the North Sea were supplied by Jim Kinnear and Jon Elson.

3 PANDALUS STOCKS IN SUB-AREA IV AND DIVISION IIIA

A detailed overview of the various stocks is given in ICES (CM 1990/Assess:9) The Working Group grouped them into three assessments units:

1. Skagerrak and Norwegian Deeps combined

2. Fladen Ground

3. Farn Deeps

Nominal landings for Division IIIa and Sub-area IV are shown in Table 3.1.

3.1 Natural mortality

The level of natural mortality for *Pandalus* has been discussed at several occasions. The value used i.e., 0.75 for Divisions IIIa, IVaE is not well founded.

Work is initiated to elucidate predation mortality, however, no changes were made in the values of natural mortality used in this year's assessments.

3.1.1 Landings

Landings are given in Table 3.1 by area (Division IIIa and Sub-area IV) as officially reported to ICES. The reported amounts for both areas are similar to the 1995 levels.

Table 3.1.1 presents the landings and estimated discards for the assessment unit, i.e. Division IIIa and eastern part of Sub-area IVa. These landings have increased compared to 1995 and are on the same record high level as in 1987, viz. around 14 200 t.

Landings from Norway and Sweden (and to a small extent from Denmark) consist of a fraction of larger shrimps that are boiled on board and a remaining portion of smaller shrimps landed fresh. The boiling causes the shrimps to loose weight. The conversion factor to obtain live weight is 1.15. Official reported figures from Norway are

given as landed weight. The same procedure has been adopted by Sweden for the last few years. In the amounts used by Working Group, the Swedish landings of large shrimps have, however, been converted to live weight. The amount added for 1996 was 171 tonnes. No conversion has been applied on the Norwegian landings by the Working Group. The underestimate of total landings by this omission is for 1996 roughly estimated to about 500 t. The Working Group felt this estimate too inaccurate to include in the assessment figures. When more accurate estimates become available, the landings for all years should be updated.

3.1.2 Discards

Discarded shrimps are of two categories:

The smallest size fractions from the sieving procedure is not accepted by the canning industry and are discarded. This practice is traditional in the Norwegian and Swedish fisheries. The Working Group estimated the amounts of discards by using the Norwegian length measurements from samples taken onboard before discarding. The proportion below 15 mm carapace length are considered discarded.

More recently, the substantial price difference between large, boiled shrimps and medium sized fresh ones has resulted in high grading by discarding the latter. The amounts of discards in this category were estimated for 1996 only. Using the proportions of large and medium sized shrimps (by month and statistical rectangle) from a time period when no high grading occurred.

The estimate of total discards in 1996 of 1280 t was added to the total catch for assessment purpose.

3.1.3 Effort

Annual figures for landings per unit of effort (LPUE) and effort are given in Table 3.1.2 Total effort values have been estimated from LPUE data based on logbook records. Swedish and Norwegian effort decreased from 1995 while Danish effort increased.

3.1.4 Assessment

3.1.4.1 Age distributions

Length frequencies from Danish, Norwegian and Swedish quarterly samples were added and weighted by the numbers of animals measured. Numbers at age were then estimated by first splitting the length frequency distributions into normal distribution using the Bhattacharya method as implemented in ELEFAN (Pauly 1987). The numbers caught by each country were then calculated from numbers per kilo in their quarterly samples and split into age groups using the combined age distribution. Quarterly growths are shown in Figure 3.1.1. Total catch in numbers at age are given in Table 3.1.3

3.1.4.2 Mean weight and maturity at age

Weights at age for 1996 were obtained by applying average Danish and Swedish mean weight per length group data to the length frequencies of each year class. The mean weights at age in the catch is given in Table 3.1.4. The same weights at age are used as stock weights.

The 0- and 1-group were assumed to be immature, and the 3+ groups fully mature. The mature part of the 2-group or potential spawners was taken as the sum of intersexes and females in the first quarter of the year. These proportions have been:

1985	1986	1987	1988	1989	1990	1991	1992	1993	1994	1995	1996
0.62	0.09	0.20	0.30	0.68	0.73	0.73	0.68	0.70	0.64	0.45	0.46

Spawning stock size has in this assessment been calculated per 1 Jan; i.e. FPROP=MPROP=0 for all years.

3.1.4.3 Natural mortality

Natural mortality has been set at 0.75 for all ages. M was, as earlier, set at 0.75 for all ages.

3.1.4.4 Assessment

An XSA was performed on the 1985-1996 dataset to estimate stock sizes and exploitation levels. Data on effort and catch per unit of effort by age for three commercial fleets and catch at age from the annual Norwegian shrimp survey was used for tuning (Table 3.1.5).

Default values were accepted, in most instances, as input variables in the XSA (Table 3.1.6). Catchabilities were, however, assumed independent of stock size for all ages, and independent of age for ages 2 and older. Survivor estimates were shrunk towards the mean F of final 5 years or the 2 oldest ages.

Fishing mortalities, expressed as unweighted mean over age groups 1-3, (see Table 3.1.7) decreased from 1992 to a minimum in 1994. This decrease is mainly due to a major drop in the high values for the 3-group.

Stock size in terms of number at age is given in Table 3.1.8. Spawning stock decreased to below the average level from 1994 to 1996. The total stock biomass increased due to the strong 1995 year class.

Summary results without SOP corrections are given in Table 3.1.9

3.1.4.5 Recruitment

The abundance indices of young shrimps obtained by the Norwegian survey in October are given in Table 3.1.10. The 1995 year class had a low 0-group index but turned out to be very strong as 1-group. The 1996 0-group index is above average and preliminary results for 1997 seems to confirm that the year class as 1-group is relatively strong.

The 1996 year-class was estimated as 0-group by a regression on XSA estimates (RCT3 was used). The input data is in Table 3.1.11 and the output in Table 3.1.12. The year-class was thus estimated to 20,286 billion.

3.1.4.6 Catch prediction

Input data for the prediction are shown in Table 3.1.13. The fishing pattern used for 1997 is the 1994-1996 average scaled to the 1996 level (mean of ages 1-3). Mean weights are averages for the period 1994-1996. Recruitment in 1996 is the RCT3 estimate. The 1996 year-class as 1-group in 1997 was taken from the RCT3 estimate and recalculated as 1-group by applying the total mortality for 1996. Recruitment in 1997 - 1999 is the geometric average for the period 1985-1996.

The spawning stock estimates are very dependent on the maturity ogive, which has varied considerably during the period of investigation. In this year's prediction the maturity for age group 2 is based on the percentage intersexes and females in the 2-group observed in Norwegian samples during quarter one 1997. The status quo landings for 1997 is predicted to 17,550 tonnes, whereas the agreed TAC is 15,000 t. Predicted status quo catches in 1998 is 17,830 assuming mean recruitment (Table 3.1.13). If the minimum recruitment observed over the 12 year period is applied the predictions is 16,860.

3.1.4.7 Management consideration

Predictions of yield and spawning stock size for the period 1997-2006 were performed based on a model developed at the Danish Institute for Fisheries Research. It is implemented in Excel. The model includes uncertainties in the estimated population size in 1997, in mean weights at age and in the proportion mature of age group 2. The uncertainty in population size in 1997 is the one estimated in the XSA. Uncertainties in mean weights and maturity are estimated from the historic data. Recruitment (at age 0) is based on the historic relationship between SSB and recruitment assuming a Ricker function. Recruitment is assumed to be lognormally distributed around the Ricker curve using the variance observed in the historic data.

The percentiles of the probability distributions after 200 runs are presented in Figure 3.1.2 for yield and SSB under constant fishing mortality at the 1997 level.

The results indicates a drop in yield and SSB to 1999 and thereafter a likely catch of about 15 000 t and a 10% risk that SSB will be less than 12 000 t.

Long-term evaluation

A stock-recruitment relationship was calculated as a Ricker curve based on the 1985-1996 data points (Figure 3.1.3). The estimated values for the parameters are $a = 2,2764$ and $b = 22,068$, when recruitment is expressed in billions and SSB in thousand tonnes. Maximum recruitment would consequently occur at around 22,000 t SSB. The rather narrow range of SSB (12,000-24,000 t), so far experienced, makes the estimation of the relationship unprecise.

Equilibrium yield and SSB based on this S-R relationship and a Yield per recruit calculation are given on Figure 3.1.4.

Biological Reference Points

The following BRPs were estimated from yield per recruit calculations and from equilibrium yield and SSB calculations based on a Ricker type relationship (Figures 3.1.3 and 3.1.4). The rather narrow range of SSB (12 000 - 24 000 t) so far experienced, makes the estimation of the relationship unprecise:

$$F_{0,1} = 0.8$$

$$F_{med} = 1$$

$$F_{MSY} = 1$$

$B_{MSY} = 15\,000\,t$

Trawl selection

The high discard figures indicate that the selection properties of commercial shrimp trawls are poor. Sorting grids or other means facilitating the escape of small shrimps should be included in the management of the stock.

3.1.4.8 Assessment quality

Most of the samples used for length frequencies for the stock assessment are from the Skagerrak area. Figure 3.1.5 shows that in the fourth quarter the length frequencies from survey in the Skagerrak area and the one used for VPA are quite similar (when the catches of 0-group caught in the fine meshed survey trawl are omitted), while there are considerable higher proportion of large ones in the Norwegian Deeps, indicating a considerable bias in sampling of commercial catches.

Stock Assessment based on Survey data

Imprecision in landing data and commercial cpue, uncertain discard estimates and the possibility of a bias in the samples of landings encouraged the WG to attempt an assessment based on Survey data only. The data from the Norwegian Surveys were analysed with the RCPUE model (Cook, 1995). Inputs are given in Table 3.1.14. Both natural mortality, maturity and mean weights at age in catch and in stock were kept constant for all years. The 0 and 4+ group were given lower relative weights in the estimation procedure as they were assumed to be more variable (noisier) than other age groups. The relative catchability is obviously much lower for the 0 group than for older shrimps. This is due to both the mesh selectivity and to their changing availability at the time of the survey. The relative catchability for this age group had to be put to 0.08 in order to avoid negative age effects.

The resulting estimates of stock size, fishing mortalities and yield are found in Table 3.1.15 in which also the diagnostic output is given.

The trends of stock estimates, yield and exploitation level obtained in this analysis and with the XSA is compared in Figure 3.1.6. The two methods give different results for the stock estimates and the yield. The two methods depict different trends of landing per recruit and yield per biomass, although they give similar trends for the exploitation level.

It is apparent that the two methods give different pictures of the stock dynamic and of yield. When exploitation is expressed as yield per biomass instead of fishing mortality, the two methods depict similar trends.

Causes for the observed differences in results from the two assessments could be the quality of the fishery related data, the constrain in the model assuming constant mean weights and natural mortality. In both models M were assumed large and constant over time. If natural mortality has varied during the period of assessment (for

example due to changes in the predation rate on shrimps) the effect on the estimates of fishing mortality (and yield) would be different in the two models as the partitioning of total mortality is performed quite differently.

The estimates of Stock biomass from the survey based assessment have in other cases been demonstrated to be fairly robust (Cook, 1995). The WG therefore made a comparison between biomass estimates/indices from surveys and from fishery based data. (XSA, RCPUE, survey data expressed as kg/hr and commercial cpue). Figure 3.1.7.

The general trends are similar between survey estimates (from RCPUE) and the fishery data (commercial cpue) with a correlation of $r= 0.74$.

3.2 Fladen Ground

Table 3.2.1 shows the landings from the Fladen Ground since 1972. Only Denmark and Scotland exploited this stock during 1996.

The total catch increased due to a doubling of Scottish effort (Table 3.2.2) There was a reduction in CPUE for both countries. No further data for assessment purpose were available.

3.3 Farn Deep

In recent years *Pandalus* in the Farn Deep have been fished by UK vessels only. Total landings fell from 500 t in 1988 to none in 1993. In 1994 there was a small fishery of 4 tonnes, 171 t in 1995 and 60 t in 1996 (Table 3.3.1).

4 BYCATCH

Bycatch in the 1996 shrimp fishery is available from Danish log books and from a Danish discard project (Table 4.1 and Table 4.2).

The Danish discard project in the North Sea was started in 1995. Information on bycatch in the Danish shrimp fishery in 1996 was collected during fishing trips with four randomly selected fishing vessels representative of the Danish shrimp fishing fleet (vessel size from 83 to 114 GRT, length from 22 to 28 m, crew of 3 or 4 men, and shrimp trawls with a codend meshsize of 36-38 mm). The entire catch (or a subsample raised to the entire catch) of all species from randomly selected shrimp fishing hauls were weighed and counted by biological assistants from the Danish Fisheries Research Institute. The number of samples (i.e. hauls) in 1996 by fishing area and quarter is given in Table 4.2.

A first estimate of the total bycatch in the international shrimp fishery was obtained by raising the species bycatch from the Danish discard project in kg and numbers per kg shrimp to the total catch of shrimp by all nations (Table 4.2).

Logbook information is usually unreliable for species other than the target species due to under or misreporting. Information from the discard project provides a check for the reliability of logbook information and allows a rough estimation of the discard of bycatch species. In general the fish not reported in logbooks are under sized and low value species not landed and therefore discarded at sea. A comparison of bycatches from logbooks and the discard project on the Fladen Ground in the 1. Quarter shows that catches of small and under sized fish e.g. Norway Pout, haddock and whiting are under reported in the logbooks, while estimates of market sized high value fish species e.g. cod and Anglerfish (Monk) using these two methods are in relatively close agreement. These trends are even more pronounced in the data from the Norwegian Deep and the Skagerrak area.

* Includes small amounts of other Pandalid shrimp.

† 1970 to 1974 includes subarea IV; from 1975 onwards, figures relate to the North Sea and the Wadden Sea area.

‡ Total 1988-1990 includes 19.21 AND 51 t. by the Netherlands.

1996 figures are preliminary.

ICES Sub-area IV is roughly bounded by the British Isles and the North Sea, extending from the Shetland Islands in the north to the Bay of Biscay in the south. It includes the North Sea and the Wadden Sea area.

ICES Sub-area IIIa is roughly bounded by the British Isles and the North Sea, extending from the Shetland Islands in the north to the Bay of Biscay in the south. It includes the North Sea and the Wadden Sea area.

The following table gives nominal landings (tonnes) of *Pandalus borealis* in ICES Sub-area IIIa (excluding subarea IV) and subarea IV as officially reported to ICES.

ICES Sub-area IIIa includes the British Isles and the North Sea, extending from the Shetland Islands in the north to the Bay of Biscay in the south.

ICES Sub-area IV includes the British Isles and the North Sea, extending from the Shetland Islands in the north to the Bay of Biscay in the south.
