## REPORT OF THE

# WORKING GROUP ON THE ASSESSMENT OF MACKEREL, HORSE MACKEREL, SARDINE AND ANCHOVY 

ICES Headquarters<br>28 September-7 October 1998

## Part 1 of 2

This report is not to be quoted without prior consultation with the General Secretary. The document is a report of an expert group under the auspices of the International Council for the Exploration of the Sea and does not necessarily represent the views of the Council.

International Council for the Exploration of the Sea
Conseil International pour l'Exploration de la Mer

## Summary

The Working Group reports on the state of the stocks of western, southern, and north-east-Atlantic mackerel, southern horse mackerel, western horse mackerel, sardine and anchovy in Divisions VIIIc and IXa, and anchovy in Sub-Area VIII. Corresponding catch forecasts are provided. No estimates of the state of the stocks of mackerel in the North Sca, horse mackerel in the North Sea nor of anchovy in Division IXa are made because of a lack of biological information. Biological sampling of catches has been reviewed. Southern horse mackerel catches are very well covered by the sampling programme. Sampling of commercial catches for sardine, for anchovy in VIII and for mackerel is considered adequate. Sampling coverage for western horse mackerel is poor. No new assessment is calculated for North-East Atlantic mackerel nor for Western mackerel, but a stock projection made from the previous assessment and using reported catches in 1997 agrees well with information analysed to date from the mackerel egg surveys in 1998. The stock appears to be relatively stable at present. Available data on mackerel distributions have been collated. The preliminary information from the western horse mackerel egg surveys indicates a much higher stock size than was expected. The assessments have been revised accordingly, but methodological problems with the assessment of this stock remain to be addressed. The assessments of both north-east Atlantic mackerel and western and southern horse mackerel will be updated in early 1999 when the analysis of egg survey information is complete. The assessment of Southern horse mackerel is closely consistent with that presented previously and there is little change in the perception of the dynamics of this stock. A new sardine assessment model has been formulated to address some methodological problems which have been discovered since the previous Working Group meeting. The perception of the state of the stock remains one in which recruitment is declining and fishing mortality increasing, but estimates of stock size in the 1970 s and early 1980 s relative to recent stock sizes are now known to be unreliable. A weak recruitment is estimated for anchovy in VIII in 1998, and the stock is expected to decline in 1999 as the strong 1996 and 1997 year-classes cease to contribute to the adult stock. Environmental indices of recruitment have been used for anchovy in VIII and have been proposed for sardine.

## Résumé

Le Groupe de Travail s'est intéressé à l'état des stocks de maquereaux de l'Ouest, du Sud et du Nord-Est Atlantique, de chinchards du Sud et de l'Ouest, de la sardine et de l'anchois des Divisions CIEM VIIIc et IXa et de l'anchois de la sous-zone CIEM VIII. Les prévisions de captures ont été fournies. Aucune estimation sur l'état des ressources du maquercau et du chinchard en mer du Nord ainsi que de l'anchois de la Division CIEM IXa n'a pu être fournie compte tenu du manque d'informations sur la biologie de ces espèces. Les échantillons biologiques des captures ont été analysés dans le cadre de la détermination des structures d'âge des populations capturées. Les échantillonnages des captures commerciales pour la sardine et l'anchois de la Division VIII et pour le maquereau sont considérés comme suffisants. Tandis que celui du chinchard de la zone Atlantique Ouest peut être considéré comme très insuftisant. Aucune nouvelle évaluation n'a été effectuée ni pour le stock de maquereaux du Nord-Est Atlantique ni pour celui du stock Ouest. Cependant, une prévision sur l'état du stock, effectuée à partir des évaluations existantes et en utilisant les captures déclarées en 1997, concorde bien avec les informations actuellement collectées lors des campagnes d'évaluation de la répartition et de l'abondance des oeufs en 1998. Le stock apparaît s'être relativement stabilisć. Les données disponibles sur les distributions des maquereaux ont été récoltées. L'information provenant de l'analyse préliminaire des campagnes de suivis des oeufs de chinchards indique que le niveau d'abondance du stock est plus élevé que ce que l'on pensait. Les évaluations ont donc pu être ainsi révisćes, mais des problèmes méthodologiques concernant l'évaluation de ce stock demeurent. Les estimations d'abondance des stocks de maquereaux du Nord-Est Atlantique ainsi que du chinchard des zones Ouest et Sư Atlantique doivent être revues en 1999 à la lumière de l'analyse complète des informations collectées lors des campagnes de suivi des densités d'oeufs. L'évaluation du stock de chinchard du Sud est cohérente avec celle qui a été effectuée l'année passée et peu de changements dans la dynamique de ce stock sont constatés. Un nouveau modèle pour l'évaluation de l'abondance du stock de sardines a été formulé pour prendre en compte certains problèmes méthodologiques qui sont apparus depuis la précédente réunion du Groupe de Travail. La perception de l'état de cette ressource est caractérisée par un recrutement déclinant et une mortalité par pêche qui s'accrô̂t. Cependant, les estimations concernant la taille de ce stock dans les années soixante-dix et le début des années quatre-vingts ne sont pas considérées comme fiables. Pour l'anchois de la zone VIII, on estime, à partir des indices environnementaux, que l'on aura un faible recrutement pour l'année 1998 aboutissant à une diminution de l'abondance de cette espèce en 1999, compte tenu de la diminution de l'impact des cohortes 1996 et 1997 sur l'abondance de la population d'anchois adultes du golfe de Gascogne. Des indices de recrutement basés sur la variabilité des facteurs environnementaux (indices prenant en compte l'importance des remontées d'eaux froides) a été utilisé pour l'anchois et a été proposé pour la sardine.

## Table of Contents

## Part 1

1 INTRODUCTION ..... 1
1.1 Terms of Reference .....  1
1.2 Participants ..... 1
1.3 Report on Progress with Respect to Recommendations ..... 2
1.4 Quality and Adequacy of Fishery and Sampling Data ..... 3
1.4.1 Sampling data from commercial fishery ..... 3

### 1.1 Terms of Reference

The Mackerel, Horse Mackerel, Sardine and Anchovy Working Group met at ICES Headquarters from 28 September-7 October 1998 to address the following terms of reference, as decided at the 85th Statutory Meeting (1997 Annual Science Conference) (C.Res.1997/2:11:9):
a) assess the status of and provide catch options for 1999 for the stocks of mackerel and horse mackerel (defining stocks as appropriate);
b) assess the status of and provide catch options for 1999 for the sardine stock in Divisions VIIIc and IXa, and the anchovy stocks in Sub-Area VIII and Division IXa;
c) provide the data required to carry out multispecies assessments (quarterly catches and mean weights at age in the catch and stock for 1997 by statistical rectangle of the North Sea for mackerel and horse mackerel) and review the time series of quarterly catch and weights at age for North Sea mackerel, western mackerel, North Sea horse mackerel and western horse mackerel used by the MAWG in Doc. ICES CM 1997/Assess:16, suggesting and documenting any necessary revisions to those series;
d) consider the reference points proposed by the SGPAFM, adopting those reference points or presenting alternatives with reasons for the alternative selection;
e) consider the harvest control rules proposed by the SGPAFM, taking into account uncertainties in the data, in the assessments and in the biological processes, and assuming a stock-recruitment relationship, to estimate the probability of avoiding limit reference points;
f) update information on quantities of discards by gear type for the stocks and fisheries considered by this group using the format proposed by the WGECO with a view to establishing a time series;
g) quantify changes in sardine and anchovy recruitment in the Iberian region and the Bay of Biscay and investigate possible relationships between any environmental parameters available and indices of recruitment.

In response to an additional term of reference received by ICES from NEAFC, the Working Group was also asked to:
h) collect and evaluate the available data on the area distribution of mackerel in the NEAFC area for juvenile as well as parental components and advise NEAFC on what further rescarch is needed in order to give a comprehensive description of the distribution and possible technical interaction.

### 1.3 Report on Progress with Respect to Recommendations

The Working Group reviewed the progress which had been made in respect to the various recommendations which had been made at the 1997 meeting. This is reviewed briefly as follows.

## Mackerel

The observer programme to monitor discards in the mackerel/horse mackerel fleets which had been strongly recommended has not been put in place.

The mean weights at age in the stock, calculated from Irish data, have been used together with Dutch data as the best estimates of the weights for the stock at spawning time.

Distribution patterns in the North Sea and VIa North have not been further investigated.
Mackerel egg surveys will be carricd out in the North Sea during 1999.
Modelling work is currently in progress on improving the use of the juvenile surveys for recruitment predictions.
A new project on mackerel recruitment, entitled SEAMAR (Shelf Edge Advection, Mortality and Recruitment) will start on $1 / 1 / 99$. This project is aimed at modelling larval survival through to recruitment. Participants are from Scotland, England, Spain, Portugal, Germany and Ireland.

## Horse Mackerel

There has been no improvement in the age reading programmes carried out by countries on horse mackercl in 1997. This, however is expected to improve in 1998 as Ireland has commenced an age reading programme.

A horse mackercl age reading workshop is expected to be held early in 1999.
No further research has been carried out on North Sca horse mackerel.
Studies on the stock identity and migration patterns of Southern horse mackerel are being carried out but the results have not yet been fully analysed.

## Sardine

Acoustic surveys have been carried out in 1998 but have covered the entire area recommended. This, however, is not the entire area over which the stock is distributed.

A planning group was held in relation to the acoustic surveys.
Recommendations agreed at the 1997 Workshop on Sardine Otolith Age Readings were implemented. An exchange of otoliths from the Gulf of Cadiz was arranged under the EU funded EFAN project.

## Anchoyy

Further studies on ageing of anchovy either by otoliths or other methods in the Gulf of Cadiz were carricd out.
Coordinated acoustic surveys between France and Spain in the Bay of Biscay but no joint surveys were conducted in the Gulf of Cadiz.

Collection of information physiology of anchovy in relation to post-spawning mortality were conducted.

## General

Egg Survey Working Group is expected to meet in Hamburg in April 1999.

## ICES

A complete set of the relevant Working Group reports has not been made available to the Working Group as requested.

### 1.4 Quality and Adequacy of Fishery and Sampling Data

### 1.4.1 Sampling data from commercial fishery

The Working Group again carried out a brief review of the sampling data and the level of sampling on the commercial fisheries. Sampling appears to be adequate for mackerel (approx. $83 \%$ coverage of catch), sardine and anchovy but poor for horse mackerel in the western areas and in the North Sea. A short summary of the data, similar to that presented in recent Working Group is shown for each stock species. The overall sampling intensity is similar in recent years. Intensive sampling programmes continue to be carried out by Spain and Portugal. On the other hand, sampling programmes on some of the large northern fisheries, particularly horse mackerel is very inadequate. Sampling programmes in Spain, Portugal, Ireland, England, France have been supported by an EU funded programme, 94/013. The sampling programme on the various species is summarised as follows.
Mackerel

| Year | Total catch (t) | \% Catch covered by sampling programme | Samples | Measured | Aged |
| :--- | :---: | :---: | :---: | :---: | :---: |
| 1992 | 760,000 | 85 | 920 | 77,000 | 11,800 |
| 1993 | 825,000 | 83 | 890 | 80,411 | 12,922 |
| 1994 | 822,000 | 80 | 807 | 72,541 | 13,360 |
| 1995 | 755,000 | 85 | 1,008 | 102,383 | 14,481 |
| 1996 | 563,600 | 79 | 1,492 | 171,830 | 14,130 |
| 1997 | 569,600 | 83 | 1,067 | 138,845 | 16,355 |

In mackerel it appears that over $83 \%$ of the total catch was covered by sampling. The overall sampling level appears to have decreased during 1997 and returned to the level of 1995. Spain and Portugal continue to carry out extremely intensive programme on their catches but Germany did not continue with their sampling programme which it had commenced in 1996. Norway and UK (Scotland) reduced their programmes but on the other hand Netherlands and UK (England) increased their programmes. Denmark only carries out sampling on their catches during the fourth quarter. There are still, however, a number of important mackerel catching countries which did not carry out any sampling programmes, e.g. Faroes, France, Germany and Sweden.

The main areas, that do not appear to be adequately sampled, are Division IIIa $8,000 \mathrm{t}$ (Denmark), Division VIIIc $3,400 \mathrm{t}$ (France), Division VIId $8,500 \mathrm{t}$ (England). The summarised details of the more important mackerel catching countries are shown in the following table for 1997:

| Country | Official Catch | Catch covered by sampling programme | Samples | Measured | Aged |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Norway | 137,300 | 100 | 130 | 11,877 | 1,508 |
| UK (Scotland) | 105,100 | 89 | 55 | 4,380 | 2,185 |
| Russia | 53,700 | 100 | 57 | 7,886 | 685 |
| Ireland | 53,100 | 99 | 63 | 11,869 | 4,138 |
| Spain | 46,500 | 100 | 361 | 5,4274 | 2,671 |
| UK(England) Wales) | 43,800 | 58 | 53 | 12,513 | 2,129 |
| Netherlands | 23,700 | 100 | 76 | 6,083 | 1,900 |
| Denmark | 22,000 | 63 | 4 | 219 | 74 |
| France | 21,000 | 0 | 0 | 0 | 0 |
| Germany | 15,400 | 0 | 0 | 0 | 0 |
| Faroes | 11,200 | 0 | 0 | 0 | 0 |
| Sweden | 4,700 | 0 | 0 | 0 | 0 |
| Estonia | 1,400 | 95 | 425 | 29,744 | 1,065 |
| Portugal | 2,100 | 0 | 0 | 0 | 0 |
| Others + discards | 24,100 |  | 1,076 | 138,845 | 16,355 |
| Total | 568,100 |  |  | 0 |  |

## Horse Mackerel

The following table shows a summary of the overall sampling intensity on horse mackerel catches in recent years.

| Year | Total catch $(t)$ | Catch covered by sampling programme | Samples | Measured | Aged |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1992 | 436,500 | 45 | 1,803 | 158,447 | 5,797 |
| 1993 | 504,190 | 75 | 1,178 | 158,954 | 7,476 |
| 1994 | 447,153 | 61 | 1,453 | 134,269 | 6,571 |
| 1995 | 580,000 | 48 | 2,041 | 177,803 | 5,885 |
| 1996 | 460,200 | 63 | 2,498 | 208,416 | 4,719 |
| 1997 | 518,900 | 75 | 2,572 | 247,207 | 6,391 |

Although the overall sampling levels on horse mackerel has increased considerably in recent years there are still a number of countries that have substantial fisheries and do not carry out adequate programmes. The only countries that carried out comprehensive sampling programmes in 1997 were Netherlands, Portugal and Spain. Other countries, e.g. Ireland, Denmark and United Kingdom carry out no ageing programmes whatsoever. The lack of sampling data for large portions of the horse mackerel catch continues to have a serious effect on the accuracy and reliability of the assessment and the Working Group remains concerned about the low number of fish that have been aged during the last 4 years.

The following table shows the most important horse mackerel catching countries and the summarised details of their sampling programme in 1997:

| Country | Catch (t) | Catch covered by sampling programme | Samples | Measured | Aged |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Netherlands | 122,684 | 122,684 | 98 | 1,0936 | 2,450 |
| Ireland | 74,250 | 38,835 | 25 | 3,639 | 0 |
| Denmark | 63,077 | 59,617 | 50 | 1,390 | 0 |
| Norway | 46,484 | 43,846 | 21 | 1,819 | 193 |
| Spain | 41,993 | 41,987 | 678 | 50,987 | 752 |
| Germany | 36,379 | 0 | 0 | 0 | 0 |
| Scotland | 32,894 | 0 | 0 | 0 | 0 |
| Others | 22,345 | 21,260 |  |  |  |
| England | 20,047 | 0 | 0 | 0 | 0 |
| Portugal | 18,659 | 18,659 | 1,717 | 178,436 | 2,996 |
| Total | 478,812 | 346,888 | 1,717 | 247,207 | 6,391 |

*Includes discards, small catches by other countries, and some unallocated catches.
The sampling coverage for the various fisheries are shown below:

| Catch | \% Catch covered by sampling | Samples | Measured | Aged |
| :--- | :---: | :---: | :---: | :---: |
| Ireland | 52.3 | 25 | 3,639 |  |
| Netherlands | 100 | 98 | 10,936 | 2,450 |
| Norway | 94.3 | 4 | 1,819 | 193 |
| Spain | 100 | 678 | 50,987 | 752 |
| England | 0 |  |  |  |
| Spain | 94.5 | 50 | 1,390 |  |
| Germany | 100 | 1,717 | 178,436 | 2,996 |
| Portugal |  |  |  |  |
| Scotland | 96.8 | 2572 | 24,7202 | 6,391 |
| Others $(22,345 \mathrm{t})$ <br> Total $(518,882 \mathrm{t})$ | 74.6 |  |  |  |

The sampling intensity for the western fisheries was as follows:

| Catch | \% Catch covered by sampling | Samples | Measured | Aged |
| :--- | :---: | :---: | :---: | :---: |
| Ireland | 52.3 | 25 | 3,639 | 0 |
| Netherlands | 100 | 75 | 8,039 | 1,875 |
| Norway | 94.3 | 4 | 1,819 | 193 |
| Spain | 99.7 | 38 | 2,608 | 52 |
| Denmark | 94.5 | 50 | 1,390 | 0 |
| Portugal | 100 | 27 | 1,862 | 0 |
| Others $(144,273 \mathrm{t})$ | 0 | 0 | 0 | 0 |
| Total Catch $(442,571 \mathrm{t})$ |  | 219 | 19,357 | 2,120 |

The sampling intensity for the North Sea fishery was as follows:

| Catch | \% Catch covered by sampling | Samples | Measured | Aged |
| :--- | :---: | :---: | :---: | :---: |
| Netherlands | 100 | 23 | 2,897 | 575 |
| Others $(8,324 \mathrm{t})$ | 0 | 0 | 0 | 0 |
| Total catch $(19,540 \mathrm{t})$ |  | 23 | 2,897 | 575 |

The sampling intensity for the Southern fishery was as follows:

| Catch | \% Catch covered by sampling | Samples | Measured | Aged |
| :--- | :---: | :---: | :---: | :---: |
| Spain | 100 | 640 | 48,379 | 700 |
| Portugal | 100 | 1690 | 176,574 | 2,996 |
| Total catch $(56,771 \mathrm{t})$ | 100 | 2330 | 224,953 | 3,696 |

Many of the important fisheries carried out throughout Sub-Areas VI and VII remain inadequately sampled and catches have to be converted to numbers at age using data based on the Dutch sampling programme. As has been pointed out many times this procedure may not be appropriate, particularly if fisheries are carried out by vessels using different gears and at different times of the year.

## Sardines

The sampling programmes carried out on sardines in 1997 were again very similar to the programmes of recent years and are summarised as follows:

| Year | Total catch $(t)$ | Catch covered by sampling programme $\%$ | Samples | Measured | Aged |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1992 | 164,000 | 79 | 788 | 66,346 | 4,086 |
| 1993 | 149,600 | 96 | 813 | 68,225 | 4,821 |
| 1994 | 162,900 | 83 | 748 | 63,788 | 4,253 |
| 1995 | 138,204 | 88 | 716 | 59,444 | 4,991 |
| 1996 | 126,926 | 90 | 833 | 73,220 | 4,830 |
| 1997 | 115,814 | 97 | 790 | 79,969 | 5,133 |

In general the overall sampling intensity remains at a satisfactory level and good coverage is maintained throughout the year. No sampling programmes are carried out by France or Denmark.

The summarised details of individual sampling programmes in 1997 are shown below:

| Country | Catch (t) | Catch covered by sampling programme | Samples | Measured | Aged |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Portugal | 81,156 | 81,156 | 444 | 48,193 | 3,400 |
| Spain | 34,658 |  | 346 | 31,776 |  |
| France | 14,105 | 0 | 0 | 0 | 0 |
| UK (England) | 4,907 | 4,830 | 6 | 683 | 0 |

## Anchovy

The sampling programmes carried out on anchovy in 1997 are summarised below. The programmes are shown scparately for Sub-area VIII and for Division IXa. Sampling throughout Divisions VIIb+d and VIIIc appears to be satisfactory. No sampling programme (ages and lengths) is carried out on catches ( $5,500 \mathrm{t}$ ) taken from Division VIIIa although these catches are sampled for size category.

The overall sampling levels for recent years are shown below:

| Year | Total catch $(t)$ | Catch covered by sampling programme (t) | Samples | Measured | Aged |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1992 | 40,800 | 37,700 | 289 | 17,112 | 3,805 |
| 1993 | 39,700 | 39,700 | 323 | 21,113 | 6,563 |
| 1994 | 34,600 | 34,400 | 281 | 17,111 | 2,923 |
| 1995 | 42,104 | 35,048 | $?$ | $?$ | $?$ |
| 1996 | 38,773 | 36,053 | 214 | 17,800 | 4,029 |
| 1997 | 27,440 | 20,966 | 258 | 18,850 | 5,194 |

The sampling programmes for France and Spain are summarised below:

| Country | Division | Catch (t) | Catch covered (t) | Samples | Measured | Aged |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: |
| France | VIIIa | 5528 | 0 | 0 | 0 | 0 |
| France | VIIb,d | 6303 | 6303 | 61 | 2968 | 1590 |
| Spain | VIIIb,d | 3937 | 3937 | 55 | 2957 | 1089 |
| Spain | VIIIc(east) | 6072 | 6067 | 114 | 8034 | 2515 |
| Spain | VIIIc(west) | 307 | 0 | 0 | 0 | 0 |
|  |  |  |  |  |  |  |
| Country | Division | Catch (t) | Catch covered (t) | Samples | Measured | Aged |
| Spain | Div. IXa | 4654 | 4654 | 28 | 4891 | 0 |
| Portugal | Div. IXa | 631 | 0 | 0 | 0 | 0 |
| Total | Div. IXa | 5285 | 4654 | 28 | 4891 | 0 |

### 1.4.2 Catch data

Recent Working Groups have on a number of occasions discussed the accuracy of the landings statistics and the possibility of large-scale underreporting or species and area misreporting. These discussions applied particularly to mackerel and horse mackerel in the northern areas. This topic was again discussed by the present Working Group.

For mackerel and horse mackerel it was concluded that in the southern arcas the catch statistics appear to be satisfactory. In the northern areas it was concluded that in 1996 and 1997 there has been a considerable improvement in the accuracy of the total landing figures. This is because of tighter enforcement of the management measures in respect of the national quotas and because of the increasing awareness of the importance of accurate catch figures for possible zonal attachment of some stocks. There is still, however, large-scale area misreporting of catches particularly in Areas IV, VI and VII and possibly some species misrcporting. Underreporting of catches because of transshipping of catches at sea has decreased in recent years because most of the catches are now landed to factories ashore. Information on discard levels is available for only one fleet but discards may also be carricd out by other fleets. Therefore the total amounts discarded may be underreported. (see Section 1.4.3 below).

### 1.4.3 Discards

## Mackerel

Only one country (Netherlands) supplies information on discards and this information is not applied to any other fleet. There is no new information on discard levels during 1997.

Discarding of small mackerel has historically been a major problem in the mackercl fishery and was largely responsible for the introduction of the south-west mackerel box. In the years prior to 1994 there was evidence of large-scale discarding and slipping of small mackerel in the fisheries in Division IIa and Sub-area IV, mainly because of the very high prices paid for larger mackerel ( $>600 \mathrm{~g}$ ). This factor was put forward as a possible reason for the very low
abundance of the 1991 year class in the 1993 catches in numbers at age. In some fisheries, e.g. those in Sub-areas VI and VII, mackerel is taken as a by-catch in the horse mackerel fisheries. Reports from these fisheries have suggested that discarding may be significant because of the low mackerel quota relative to the high horse mackerel quota - particularly in those fisheries carried out by freezer trawlers. In the fisheries carried out in Divisions IIa and IVa the difference in prices paid for small and large mackerel has decreased since 1994 and the Working Group assumed that discarding may have been reduced in these areas. The level of discards is greatly influenced by the market prices and by quota.

In autumn 1997 an EU-funded programme involving Norway and Scotland commenced with the intention of studying the performance of the purse seine fisheries for herring and mackerel. This programme which will continue over two years will provide data on discards for these fleets. The Working Group would also like to draw attention to the possibility that discarding of small mackerel may again become a problem in all areas particularly if a strong year class enters the fishery.

An EU programme carried out by Spain studied the rate of discards of all species taken by the Spanish fleets, fishing in Sub-areas VI, VII, VIIIc and IXa. The results of this study (Perez et al. 1994) showed that the discard rates varied by species, area and fishing fleet. The observed levels of discards were between $0.2 \%-25.7 \%$ for horse mackerel, between $0.1 \%$ and $8.1 \%$ for mackerel and less than $1 \%$ for sardine.

## Horse mackerel

As with mackerel only the Netherlands provides information on discards in the horse mackerel fisheries. The amounts of horse mackerel discarded by the Dutch fleet represents a much smaller proportion ( $3 \%$ ) of their total catch than in the mackerel fisheries ( $79 \%$ ) and there appears to be no apparent reason why vessels would discard significant amounts apart from losses due to damage to nets. There appears to be no significant amounts of discarding in the Southern horse mackerel fishery but there is no data available.

## Sardine

Discarding in the sardine fishery is not considered to be a significant problem but there are no estimates available.

## Anchovy

As in the sardine fishery there are no estimates of discards in the anchovy fishery but there does not appear to be any significant problem.

Because of the potential importance of significant discard levels on the mackerel and horse mackerel assessments the Working Group again recommends that observers should be placed on board vessels in those areas in which discarding may be a problem. This observer programme should be commenced as soon as possible.

### 1.4.4 Age reading

The quality of the age data for the various assessments depends on 1) the accuracy and precision of the age readings of each species, and 2) the sampling intensity which enables the catches to be converted into numbers at age. The Working Group examined the various species with respect to these factors. Factor 1 is dealt with in this Section, but factor 2 is dealt with in Section 1.4.1.

## Mackerel

A mackerel otolith exchange in 1994 showed that the ageing was of a poor quality. Therefore an otolith workshop was held in February 1995 (ICES 1995/H:1). This improved the quality considerably, and the Working Group now has more confidence in the precision of the age readings.

## Horse Mackerel

A horse mackerel otolith exchange was carried out in 1996. The results showed that there is a considerable bias in the age readings. The results of the exchange are described in ICES (1998/Assess:6) and in Eltink (1997).

As in recent ycars, the only countries carrying out age readings on otoliths of horse mackerel are the Netherlands, Spain, Portugal and Norway. For the western area the catches of the non-sampling countries use the age compositions of either the Netherlands or Norway (only for the Divisions IIa and IVa area) to raise these to their own catches. In some cases this causes serious problems, e.g. where in a certain area/period the Netherlands took only one sample because of low Dutch catches and the Dutch age composition was then raised to the high catches of non-sampling countries. The quality
of the catch in numbers at age would improve considerably, if the non-sampling countries, with relatively high catches would start to age horse mackerel and would take samples for ageing relative to their catches. It is therefore extremely important that countries like Ireland, Denmark and the United Kingdom should initiate ageing programmes immediately. The text table below shows how the number of otolith readings relates to the catches by country for all areas in 1997. The position is little changed from that reported for 1996 (see Section 4.7).

| Country | Catch $(\mathrm{t})^{*}$ | Otoliths read |
| :--- | :---: | :---: |
| Netherlands | 122,700 | 2,450 |
| Ireland | 74,200 | 0 |
| Denmark | 63,100 | 0 |
| Portugal | 18,700 | 2,996 |
| UK | 52,900 | 0 |
| Norway | 46,500 | 193 |
| Spain | 42,000 | 752 |
| Germany | 36,400 | 0 |
| Others | 22,300 | 0 |

*This includes discards.

## The Working Group, once again, strongly recommends that all countries with relatively high horse mackerel catches should sample for age at an adequate level.

## Sardine

In 1997, a Workshop on Sardine Otolith Age Reading was held in IEO, Vigo (Spain), following the sardine otolith exchange between Spain and Portugal carried out during 1996. Otolith samples collected in different areas and seasons off the Atlantic-Iberian coasts were analysed. It was concluded that there was a general good agreement between readings of the different readers involved and that the readings of the Spanish reader, who is responsible for the age length keys, were the most consistent. There was also a reasonably good agreement between those readings and the readings made by the most experienced Portuguese readers.

This Workshop produced several recommendations aiming at improving the age readings and also adopted a protocol with the criteria for the standardisation of sardine age determination. It was also planned that this protocol will be produced as a guide which will assist all otolith readers in the future.

A further problem has arisen in the last year with the appearance of a different growth pattern in the younger age groups ( 0,1 ). This may lead to misinterpretation of the age of these younger age groups in the future.

## Anchovy

The age readings of anchovy and the age sampling of all the catches continue to appear to be satisfactory in Sub-area VIII. In Division IXa the age sampling of the catches appears to be satisfactory but there is not a well established methodology for age determination.

### 1.4.5 Biological data

The main problems in respect to the biological data (except age reading), which are identified by the Working Group for the various species, are as follows:

## Mackerel

The proportion mature of 1 -, 2- and 3-year old mackerel appears to be overestimated in the present maturity ogive. This is because first of all it is based mainly on a visual assessment of maturity stage without the necessary histological evaluation. Furthermore it is potentially biased by disproportionate sampling in nominally adult and juvenile areas.

The sampling for adult parameters during the 1998 egg surveys included a strategy to ensure that a new maturity ogive, based on fish in both juvenile and adult areas, and with histological evaluation, can be produced. These new data will be available at the next Mackerel and Horse Mackerel Egg Working Group meeting in April 1999.

## Horse mackerel

The selection of an appropriate maturity ogive for the western horse mackerel stock still presents major difficulties. This affects the accuracy of the assessment. As in the case of mackerel above, sampling targeted at resolving this problem was carried out during the 1998 egg surveys and will be available in April 1999.

There exists uncertainty about the level of natural mortality (ICES 1998/Assess:6).

## Sardine

The maturity ogive is decreasing to older ages, a feature which seems to be generated by problems in sampling for maturity.

## Anchovy

The main biological problems for anchovy lies in understanding the migration of 0 -group fish and their pre-recruit distribution. Information is also required about variations in natural mortality (M) as M may increase dramatically immediately after spawning has been completed. A better understanding is needed of seasonal growth in weight and length to modulate the time evolution over time of cohorts, because of the large seasonal changes in growth. The input of hydroclimatic conditions on the recruitment success needs to be better understood since the physical conditions strongly affect the strength of the recruitment.

### 1.5 Progress Report from the Mackerel and Horse Mackerel Egg Survey Working Group

### 1.5.1 Historic data series

Plankton surveys, targeted at mackerel and horse mackerel eggs, have been carried, out on a triennial basis, in the western area since 1977. They were initially set up to provide an estimate of the spawning stock size of the western mackerel in the absence of time series data from the fishery on which to base a standard assessment. This was at a time of rapid growth in the exploitation of the stock with catches increasing from a few thousand tonnes annually to over 400,000 tonnes in 1975. This was set against the background of the dramatic collapse of the North Sea mackerel fishery in the early 1970s. The surveys, initially designed to cover the spawning of mackerel, also provided information on the spawning of horse mackerel. They have also been used to provide an estimate of the spawning stock biomass of horse mackerel since 1987 with back calculations made to the 1977 survey.

Over the twenty-one year period of the surveys changes have been made in the way the surveys are carried out and the data analysed. Changes in sampling procedures were comprehensively documented in the report of the Mackerel and Horse Mackerel Egg Production Workshop (ICES 1994/H:4). Changes have also been made in the sampling, analysis and interpretation of data on fecundity, maturity and sex ratio of both species. Many of the changes have resulted from related research projects which have provided new knowledge of the biology of both specics.

As a result of the changes to egg production estimates and to adult parameters, retrospective changes have been made to the estimates of SSB of both species. These changes have been made, either by the Egg Working Group and endorsed by the assessment Working Group, or as a result of decisions made by the assessment Working Group. They are listed in Table 1.5.1.1 (mackerel) and Table 1.5.1.2 (horse mackerel). The reasons for those changes are best explained by detailing the major factors which have contributed to them.
a) Sex ratio

## Mackerel:

Observations made during the 1977 surveys suggested a sex ratio of 1:1.64 females to males. This was not supported by further investigation and the expected ratio of $1: 1$ was eventually used for the 1977 and all subsequent surveys.

## Horse mackerel:

A sex ratio of $1: 1$ is used.

## b) Interpolated rectangles

Protocol permits an interpolated value to be used for an unsampled rectangle where there are two or more adjacent sampled rectangles. For the 1977 survey the interpolated value was calculated using the geometric mean of all adjacent
rectangles including those diagonally adjacent. In 1993 the Assessment Working Group (Anon. Assess:19) recommended the use of the arithmetic mean instead of the geometric mean.

## Mackerel:

Corrections, using the arithmetic means, were made back to the 1983 survey. Corrections were not possible for the 1977 and 1980 surveys because some of the individual rectangle data were missing.

## Horse mackerel:

Corrections, using the arithmetic means, were made back to the 1989 survey only.

## c) Potential Fecundity

## Mackerel:

For the 1977 to 1986 surveys the observed fecundity in 1986, of 1,457 eggs per gram female, was used. A new fecundity estimate was made for 1989 of 1,608 eggs per gram female. (ICES 1990/H:2). This was significantly different from the previous estimate and was used as a separate value. New estimates were also made in 1992 ( 1,569 eggs per gram female) and in 1995 (1,473 eggs per gram female). The Egg Working Group (ICES 1997/H:4) did not consider these values to be significantly different and used a mean value for 1992 and 1995 . The whole question was re-evaluated at the Assessment Working Group in October 1997 (ICES 1998/Assess:22). It was decided that where valid individual estimates of potential fecundity were made in an egg survey year, then those individual estimates should be used. For the years 1977 to 1983 where no estimates were made, the mean of the observed values for the years 1986, 1989, 1992 and 1995 of 1,526 eggs per gram female would be used. This mean figure would not be further updated as new observations are made in the future.

## Horse mackerel:

In 1987, when the estimate of egg production was first used to calculate a SSB, the only available data on fecundity were from Nazarov (1977) for the Celtic Sea area. Observations by Eltink and Vingerhoed (1989) in 1987 and 1988, in the western area provided an estimate of 1,655 cggs per gram female which was used retrospectively in 1989. New observations in 1992 ( 1,454 eggs per gram female) were initially applied to the 1992 survey only and then combined with previous estimates to produce a mean fecundity of 1,589 eggs per gram female. The reasons for combining the observations was that this provided a better coverage of the length distribution.
d) Atresia

## Mackerel:

Following detailed research into the spawning biology of mackerel it was recommended by the 1993 Working Group that a correction be made to the potential fecundity figure to take account of the number of atretic oocytes observed. An observed value of $8.8 \%$ atresia was accepted and applicd retrospectively to the potential fecundity figures to give a series of realised fecundity values. Further research suggested that the value of $8.8 \%$ was an underestimate and a new figure of $10.2 \%$, the mean of observations in 1992 and 1995, was used retrospectively from 1995. The Egg Working Group (ICES 1997/H:4) found significant differences between years. It was subsequently agreed (ICES 1998/Assess: 19), that the individual values for the observed years 1989, 1992 and 1995 should be used and that for the earlier years the mean of the observed values would be used. As in the case of fecundity, this mean figure will not be further updated as new observations are made in the future.

## Horse mackerel:

The supporting research on atresia in horse mackercl is not as extensive as that for mackerel. A value of $10 \%$ for atresia was first applied, retrospectively, to the estimates of SSB in 1993. Observations in 1995 confirmed that this value was too high and the new value of $3.4 \%$ was applied retrospectively in 1996.

## Mackerel:

The second period egg survey in May 1980 produced an exceptionally low value which gave a total egg production of $1.48 \times 10^{15}$ stage 1 eggs. This was rejected by the Egg Working Group in 1984 (ICES 1984/H:3) and the resultant egg production used was $1.84 \times 10^{15}$ stage 1 eggs. A review of the problem was carried out by the Egg Working Group in 1993 (ICES 1993/H:4). No new evidence could be found for rejecting the second survey point, in spite of evidence that the lower egg production produced a better fit to the historic VPA data set. The Assessment Working Group revisited the problem (ICES 1995/Assess:2) and recommended that the third survey data point, and the resultant lower egg production and SSB, be used in future. Currently both values are published in the data table.

In 1989 the first survey period generated a very high production value of $2.22 \times 10^{15}$ stage I mackerel eggs. It was subsequently found that the standard sampling strategy had been seriously violated on that survey. It was concluded that the violation had generated the abnormally high value and that it should be rejected. The resultant estimate of seasonal egg production was $1.41 \times 10^{15}$ stage 1 eggs.

Some small errors were generated when the egg survey data base was transferred from Lowestoft to Aberdeen in 1993. These affected the egg production estimates for the survey ycars 1986 and 1989 only.

Minor changes have been made to the egg production estimates in 1983 and 1986 and 1995 by the inclusion of survey data from outside the designated standard area in that year.

## Horse mackerel:

When the estimates of horse mackerel egg production were first used to calculate SSB, in 1987, some of the survey data were not then available. These data were added in 1988 and generated significant increases in the estimates of egg production and SSB.

The problems generated for mackerel egg production by the first survey in 1989 were also applicable to horse mackerel. The survey data were therefore not used.

### 1.5.2 The 1998 egg survey

The egg surveys of the western and southern areas were successfully carried out, over the period January to July, according to the plan agreed at the planning meeting in Lisbon in 1997 (ICES 1997/H:4). The number of sampling periods had to be reduced from seven to six, to match eventual availability of survey vessels.

Preliminary results from the western area only show that the surveys successfully covered the spatial distribution of horse mackerel spawning but the peak of stage 1 egg production occurred on the final survey.

The temporal distribution of mackerel spawning in the western area was well covered but spatially the western boundary, north of the Porcupine Bank, and the northern boundary was not well established in the sampling periods 4 and 5 .

The surveys began in the southern area on 17 January with Portugal surveying the whole area from $36^{\circ} \mathrm{N}$ to $43^{\circ} \mathrm{N}$ up to 31 January. In the second period, starting on 8 February, Portugal fully sampled the area from $37^{\circ} 45^{\prime} \mathrm{N}$ to $43^{\circ} \mathrm{N}$ but poor weather prevented sampling to the south of that area. A further coverage of the area south of $43^{\circ} \mathrm{N}$ by Portugal from 22 to 28 February was severely hampered by bad weather and a large area at the south-western corner south of $38^{\circ} \mathrm{N}$ was not sampled.

Spain surveyed the area from $43^{\circ} \mathrm{N}$ and along the Cantabrian coast in period 3, from 13 March to 1 April, achieving a good coverage, with the exception of five unsampled rectangles at the western edge of the standard area. Sampling in the southern area in period 4 began on 7 April and ended on 28 April. Spain experienced serious delays due to poor weather during this period. A total of 20 rectangles at the northern, western and eastern edges of the standard area were not sampled. Planned coverage by Spain (IEO) into the southern end of the western area in period 4 had to be abandoned. Sampling in the southern area, north of $42^{\circ} \mathrm{N}$ in period 5 , was carried out by Netherlands and Spain (AZTI) and in period 6 by England.

Provisional plots of the abundance of mackerel and horse mackerel eggs, off Galicia and in the Cantabrian Sea, were provided by Spain (IEO) for periods 3 and 4. Data from the other participants have not yet been fully analysed and no provisional estimates of egg production were available at the Working Group.

Sampling targets for the adult parameters (fecundity, atresia and maturity), in the southern area, were satisfactorily achieved by Spain (IEO) for both species. For mackerel atresia 19 samples ( 258 fish), for maturity 13 samples ( 347 fish) and for fecundity 2 samples ( 69 fish) were taken. For horse mackerel atresia 19 samples ( 281 fish), maturity 14 samples ( 376 fish) and for fecundity 11 samples ( 123 fish) were taken. Most of the sampling targets for mackerel and horse mackerel adult parameters were met by Portugal, with the exception of mackerel maturity targets which were undersampled in the nominal juvenile areas.

The surveys began in sampling period 3 on 15 March with good coverage of the standard area, from $44^{\circ} \mathrm{N}$ to $53^{\circ} \mathrm{N}$, by Germany with 28 duplicate samples, south of $46^{\circ} \mathrm{N}$, taken by Spain (IEO). Sampling in period 4 was carried out by Scotland and The Netherlands from 16-30 April with a full coverage of the standard area. Because of poor weather in the south, Spain (IEO) was unable to sample in the western area during period 4 . The planned samples were taken by the Netherlands instead. Sampling, targeted at the expected peak spawning for both species, in period 5 ( 26 May-13 June) was shared between The Netherlands, Norway, Ireland, England and Spain (AZTI). Sampling in the final period from 14 June-5 July was carried out by Ireland Scotland and England.

Sorting identification and staging of mackerel and horse mackerel eggs was carried out on board ship during the surveys by Scotland, Germany and Norway. Data from those countries, together with the data from Ireland, have been fully worked up and were available as numbers of stage 1 eggs produced per day, for preliminary analysis at this Working Group. The Netherlands sorted plankton samples on board ship and provided most of their data, fully worked up, to the Working Group. All the sample data from period 5 and some of the western area data in period 6, taken by England, were also available for preliminary analysis. The data from Spain (AZTI) were not available.

A provisional cstimate was made of egg production in the western area, based on the incomplete data set, and is reported for mackerel in Section 2.5 .2 and for horse mackerel in Section 6.3.

All fecundity sample collection targets in the western area were met for both species, the samples have been distributed between SOAEFD and CEFAS but have not yet been fully processed.

Samples for the estimation of atresia in both species have been taken in all periods but the samples from Spain, Norway have not yet been delivered to CEFAS for processing.

Only three of the ten planned histology samples ( 100 fish each) were collected for the estimation of the mackerel maturity ogive. Two of those were from offshore, nominally adult areas and one from a nominal juvenile area. Some additional observations of mackercl maturity were made by Norway but no samples were taken for histological screening. A total of 14 samples were taken for the estimation of horse mackerel maturity but the designated juvenile areas were under sampled compared with adult areas.

### 1.6 Quality Control Procedures

The topic of quality control was discussed and it was noted that a comprehensive assessment of this topic was outside the resources of the Working Group. As a contribution in this area, however, the Working Group decided to review its procedures for collection and maintenance of national catch, catch sampling and age-structured information.

Primary responsibility for the accuracy of national biological data lies with the national laboratories that submit such data. Data co-ordinators have the responsibility for combining, collating, and interpolating information where necessary. A number of validation checks will, however, be made by the co-ordinators (using suitable software which will be developed intersessionally) who will in the first instance report anomalies to the laboratory which provided the data. When reports of catches without accompanying sampling information arc provided, it would be helpful to provide an indication of what data could be used as representative of these unsampled catches. Information on stratification should also be provided.

The Working Group endorses the procedures recommended in the draft 'Code of practice for data handling by assessment working groups' prepared by the Study Group on Future Requirements for Fisheries Assessment Data and Software. The Working Group's approach to implementing these recommendations is that:

- An existing spreadsheet used for national data submissions will be developed further to:
(1) build in internal consistency checks,
(2) add a macro facility to export data in a standard format,
(3) be fully protected except for data entry in specified cells.
- The standard long-term data storage should be in an agreed ASCII format as specified in Patterson (WD 1998). Allocations of unsampled catches to age-distributions for calculating total international catches at age and weights at age will be made as described therein. Age distributions should always be stored together with the relevant information on sampling intensity.
- ICES is requested to provide a secure long-term electronic data storage facility to allow the Working Group to build a long-term database.
- Where possible, species-specific data validation and range-checking will be implemented in appropriate software.
- Compiled and documented programmes (and not spreadsheets) should be used in the preparation of standard tables of biological information for assessment purposes.

For anchovy, a complex method of catch sampling based on stratifying by commercial size-categories is used. Because of this, the software system described above is not suitable for this species and an alternative system should be developed.

The Working Group will document sampling coverage of the catches in two ways. Sampling effort will be tabulated against official catches by species (as in Section 1.4). The Working Group also suggests that plots of cumulative sampling effort on cumulative catch (accumulated across the area, time and Sub-Divisions which are used as data reporting units) can be used as a qualitative guide to the effectiveness of sampling effort. Examples are given as Figures 1.6.1. and 1.6 .2 . In such plots, an appropriate sampling scheme would generate roughly a straight diagonal line. From Figure 1.6 .1 it can be seen that a relatively greater sampling effort for NE Atlantic mackerel is applied to smaller catches. When this is examined by quarter (Figure 1.6.2) it can be seen that relatively large catches which are not sampled for age occur in the latter half of the year.

At ACFM's suggestion, the Working Group will provide an assessment summary for each of the stocks in the proposed format.

### 1.7 Fleet Descriptions

## Denmark

Information on the Danish fleet will be provided in next year's Working Group report.

## England and Wales (UK)

The pelagic fleet of England and Wales is small and the effort has remained relatively unchanged over the past ten years. The majority of the landings are by three midwater freezer trawlers, two purser/trawlers and five vessels using either a single or a paired mid-water trawl.

The freezer trawlers and purser/trawlers range in length from 44 to 92 metres and have an engine power of $2300-$ 6500 HP . They account for over $90 \%$ of the pelagic catch, fishing in the seasonal fisheries open to them for herring, mackerel, horse mackerel and pilchard in area V1, the North Sea and to the west of Ircland. Most of their catches are landed outside the UK.

The five mid-water trawlers range in size from 11 to 14.5 metres and from 200 to 300 HP . They fish mainly for mackerel and pilchard in Division VIIe. There is a very large fleet of between two hundred and three hundred hand liners. The majority of these vessels are less than 10 metres in length. They fish almost exclusively for mackerel in the permitted handline fishery inside the SW of the England mackerel box. Their numbers increased to the present level in the early 1990s and have remained stable since then. They account for $4 \%$ of the England and Wales mackerel catch.

## Faroe Islands

The Faroese purse-seine fishing fleet has been rather stable in number since the late 70s, with about 10 vessels. There have been a couple of new vessels bought which have replaced older vessels, and the others have installed new and more powerful main engines, sometimes with an additional segment ( 10 m ) inserted into the vessel to increase the holding capacity. At present 10 vessels are operating ( $1500-6000 \mathrm{HP}$ ).

They fish traditionally for capelin, blue whiting, herring, mackerel and horse mackerel in their traditional fishing areas (west of Ireland/UK, North Sea, Faroes, Iceland, Norwegian Sea, Norway, Jan Mayen, Barents Sea, and Svalbard). The strategy has been to fish for whatever fish catchable with purse-seines in a fishery characterised as an opportunistic seasonal fishery.

## France

The French fleet for pelagic fishes can be divided in two parts: an industrial one, comprising 3 pelagic trawlers (ca. 70 metres length) fishing for herring, mackerel and horse mackerel mainly in Division VII, together with the Dutch fleet, and an artisanal one, comprising about 150 boats fishing anchovy, mackerel, horse mackerel and sardine mainly in the Bay of Biscay and the Channel. The artisanal fleet consists of less than 20 purse-seiners, located in the Basque Country and in Southern Brittany, and pelagic trawlers fishing in pairs, generally located in the Northern part of the Bay of Biscay and in the Basque Country.

## Germany

Due to the total ban of the North Sea herring fishery in the late 70 s and the beginning of the 80s Germany started a limited mackerel fishery in areas west of the British Isles.

The former numerous German trawler fleet declined in the 80 s . After the reunification of the former German Democratic Republic (GDR) with the Federal Republic of Germany (FRG) in 1989 some aged stern trawlers from the GDR joined the fleet and increased the numbers to 17 (freezing capacity ca. $30 \mathrm{t} / \mathrm{day}$ ). In the following years some of them went out of service and only a couple of stern-trawlers of the former FRG-fleet took part in the mackerel fishery in peak scason as a consequence of an improved economic situation within the fishing company. From 1988 onwards, the pelagic fleet was partially replaced by four large freezer trawlers fishing exclusively pelagic species. They have daily freezing capacities of $120-280 t$, and were mostly financed by Dutch funds. These new ships and considerable developments in catching techniques and material (larger nets, increase of engine power etc.) led to a complete achievement of the official mackerel quota in the last couple of years.

Until the mid-80s there was almost no interest in Horse Mackerel in Germany. As a compensation for decreasing herring and mackerel catches in the ICES area since 1990, horse-mackercl catches increased, especially in SA VI and SA VII.

An overview over the development of the German pelagic trawler flect is given below:

| year | $\mathbf{1 9 8 8}$ | $\mathbf{1 9 8 9}$ | $\mathbf{1 9 9 0}$ | $\mathbf{1 9 9 1}$ | $\mathbf{1 9 9 2}$ | $\mathbf{1 9 9 3}$ | $\mathbf{1 9 9 4}$ | $\mathbf{1 9 9 5}$ | $\mathbf{1 9 9 6}$ | $\mathbf{1 9 9 7}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| no. pelagic trawlers | 1 | 1 | 1 | 2 | 4 | 4 | 4 | 4 | 4 | 4 |
| GRT | 4500 | 4500 | 4500 | 7721 | 11918 | 12050 | 12050 | 12050 | $18264^{*}$ | $18264^{*}$ |
| no. other trawlers | 10 | 10 | 10 | 17 | 17 | 14 | 14 | 13 | 11 | 8 |
| GRT | 20285 | 20285 | 18402 | 32003 | 31024 | 28211 | 25670 | 24024 | $20357^{*}$ | $17437^{*}$ |

(* since 1996 gross tomnage)

## Ireland

The Irish pelagic fleet, which specialises in fishing for mackerel, horse mackerel, atlanto-scandian herring and blue whiting, is mainly based at Killybegs on the Northwest coast. The number of vessels in this fleet is 23 . This number has increased in recent years with the addition of approximately 6 small vessels to the mackerel and horse mackerel fisheries. All vessels, with the exception of one factory ship, are refrigerated sea water vessels (R.S.W.) and use either pair or single pelagic trawls. The engine power of the tank vessels range from $860-3350 \mathrm{~kW}$, average 2014 kW . The length range from $32 \mathrm{~m}-65 \mathrm{~m}$, average 43 m . The factory trawler has 5850 kW with a length of 98 m .

New vessels are now concentrating on speed, rather than capacity, with the object of delivering better quality catches to the most lucrative markets. Vessels have continually increased the size of nets and their manoeuvrability in recent years and this, together with new sonars, has had an extremely important influence on catching efficiency.

All vessels fish under quota restrictions and for mackerel each vessel has an individual quota per week. Restrictions may shortly be in place on number of days permitted at sea. Closed seasons are also in operation. The target species for this fleet depends very much on the quotas and markets. Vessels may often change target species during the year. All vessels fish for mackerel during the open seasons in Divisions IVa, VIa, VIIb and VIIj. Fish are landed in Norway, the Faroes, Scotland and Ireland. The factory trawler fishes throughout Areas VI, VII and Division IVa, and lands mainly into Germany

Most of the horse mackerel catch has been taken during Quarters 3 and 4 from the inshore waters in the southern part of Division VIa and from VIIb, by the smaller tank vessels. In recent years the areas from which catches have been taken have expanded (Division VIIj, southern Division of Area VII, e.g. VIIe,f,g). Most of the catch is landed in Ireland for the Japanese market.

## Netherlands

The Dutch fleet on pelagic fish can be divided in two types of vessels, that use pelagic trawls: Vessels landing frozen fish: 'Freezer Trawlers", and Vessels landing fresh fish: "Cutters". The description of the fleet is given by type of vessel.

Freezer Trawlers. In 1997 the number of freezer trawlers was 14, having a mean length of 95 m and a mean engine power of $6100 \mathrm{HP} .72 \%$ of the total catch was taken in EU waters, while $28 \%$ was caught near west Africa. In EU areas in $199751 \%$ of the pelagic catch consisted of horse mackerel, $18 \%$ of herring, $16 \%$ of mackerel, $9 \%$ of blue whiting and $2 \%$ of greater argentine. Another 9 Dutch owned freezer trawlers sail under foreign flags (2 English, 4 German and 3 French).

In the period 1988-1997, the number of ships remained the same, but the catch almost doubled ( $200,000 \mathrm{t}$ to nearly $400,000 \mathrm{t}$ ). During the period 1988-1991 there was a fishery off Morocco, the US east coast and the Falklands. From 1994-1996 there was a fishery off Namibia, and from 1996 onwards an increasing fishery off Mauritania is developing for the largest trawlers. In 1995 a new type of side-scan-sonar was introduced, which improved fish detection considerably. In 1996 light pelagic trawl doors were used for catching fish near the surface.

Cutters. In 1997, 2 ships used pelagic trawls separately and 6 ships acted as pair trawlers. In summer cutters are beamtrawlers fishing for plaice and sole. In that year the number of cutters was 8 , having a mean length of 40 m and a mean engine power of 1842 HP . The total catch was taken in EU waters and consisted of $72 \%$ herring, $12 \%$ horse mackerel and $9 \%$ mackerel. During the last 10 years the number of vessels decreased as well as the catch ( $33,000 \mathrm{t}$ to 12,000 t).

## Norway

The Norwegian vessels fishing for mackerel are divided into two main groups; smaller and larger than 23.45 m ( 70 ft ). The smaller boats have to be registered as mackerel vessels but have no individual vessel quota. They are fishing on a shared quota which has been $20,000 \mathrm{t}$ in several years. This quota was increased to $30,000 \mathrm{t}$ in 1998. These vessels fish with hand lines, gill nets and purse seines.

The group of vessels larger than 23.45 m consists of some trawlers which have a total yearly quota of $3,000-5,000 \mathrm{t}$, and about 100 larger purse seiners. The purse seiners take the main part of the catches. Their share of the quota is the Norwegian TAC for the actual year minus the fixed quotas for the smaller vessels and the trawlers. All the purse seiners are fishing according to individual quotas which are related to the size of the vessel. The purse seiners are fishing directly for mackerel, horse mackerel, herring, capelin and sprat. Some of them are also equipped for blue whiting trawling.

## Portugal

The Portuguese fishing fleet operates mainly in the Portuguese EEZ. Vessels can be classified into three types: artisanal (also called polyvalent), purse-seiners and trawlers. The first type uses different types of gears, such as small seine nets, gill-nets, hook and line, traps and small trawls. Most vessels can use several of these gears simultaneously, and they are usually of very small dimensions (length of $3-20 \mathrm{~m}$, average engine power of 17 kW ). The trawlers and purseseiners are usually larger vessels (above 20 m length, $200 / 500 \mathrm{~kW}$ ) which operate only with one kind of gear.

The development of the number of vessels by gear in the mainland and islands show a decrease in all types of vessels until 1995 in the mainland. Numbers of artisanal boats reduced from 11,467 to 9,172 , numbers of purse seiners from

260 to 190 and numbers of trawlers from 148 to 114. In the last 2 years the numbers remained more or less stable. In Madeira and the Azores the number of vessels in all gears remained stable during the period considered.

Changes in the main target species were not reported for this period. The main target species are sardine, horse-mackerel and hake.

## Russian Federation (Russia)

The fishery on pelagic fish, including mackerel, is conducted by freezer trawlers which use exclusively pelagic trawls. The Russian fleet operating in the Norwegian Sea consists of two types of vessels: Large vessels with a length range of $83-120 \mathrm{~m}$, with an engine power of $2000-7200 \mathrm{HP}$, and middle-sized vessels, ranging from 59 to 62 m length, equipped with engines of $1320-2400 \mathrm{HP}$. In summer 1997 the fleet comprised 38 large and 9 middle-sized trawlers.

Russian vessels fish in a directed fishery for post-spawning mackerel migrating to the Norwegian Sea (ICES Sub-areas $\mathrm{IIa}, \mathrm{IVa}, \mathrm{Vb}$ ) for feeding. They also catch mackerel and horse mackerel as by-catch in the blue whiting and herring fishery. The major part of mackerel catches was taken in Sub-area IIa in international waters. Over the last ten years the total amount of vessels decreased by approx. $50 \%$, but the share of large vessels increased (from 53 to $83 \%$ ). The yield of mackerel increased from 27.9 to 53.7 thousand tover the last decade.

## Scotland (UK)

During 1986-1996, the overall number of vessels in the fleet has fallen from 58 to 46 . Generally there has been a decrease in the numbers of vessels less than 49 m accompanied by an increase in the numbers of vessels over 50 m . The catching power of the fleet has also increased along with vessel size. The number of vessels using the purse seine has declined from 46 in 1986 to only 29 in 1996. From about 1991, there has been an increase in the numbers of single vessels over 50 metres using the pelagic trawl (see following table).

The main target species for the Scotlish pelagic fleet in the period 1986-1997 were herring and mackerel in arcas VIa and IVa. However in 1997, landings of blue whiting and horse mackercl increased considerably. Preliminary data for 1998 indicate that this trend is likely to continue.

PPT=Pelagic pair trawl, PSE=Purse seine, SBPT=Single boat pelagic trawl

## Spain

In the ICES area a considerable part of the Spanish fishing fleet is fishing close to the littoral, although they sometimes work at some distance from the coast. This multispecies fishery is exploited by several fleets. A seasonal exploitation, depending on the presence and abundance of species throughout the year, is characterising it.

The fishery is characterised by their seasonal nature and their exploitation depends on the presence and abundance of species throughout the year. This holds especially truc for the pelagic fishery, the so-called 'costeras'. This fleet can be divided into several sections. Their share of the total catch highly depends on the season as well as the geographical region.

Purse-seine fleet: its main target species are anchovy and sardine. Almost $100 \%$ of the catch of these two species is obtained by this fleet, which also catches horse mackerel and mackerel though always in relation to the availability of the target species.

Hand-line fleet: this fleet is aimed at mackerel from March to May in Sub-division VIIIc East and the Spanish part of Division VIIIb.

Trawl fleet: The trawl fleet targets demersal species, but catches pelagic species associated with them, mainly horse mackerel and, in small quantities, mackerel. In the Gulf of Cadiz some trawlers also catch anchovy eventually, when the abundance of other demersal species of interest to the fleet falls. The trawl fleet uses different bottom trawls ('baca', 'bou' and pair-trawl), 'baca' being the most widely used gear.

Gillnet fleet: this fleet targets demersal species and catches horse mackerel and mackerel in small quantities.
Artisanal fleet: consists of vessels of very small size, which have a wide variety of gears, mainly different gillnets and hand-lines, which catch species on rocky bottoms.

During the last 5 years (there are no homogeneous data available prior to 1993), the purse-seine fleet has decreased its number of vessels (from 261 to 226) and increased the mean power (from 403 to 440 HP) in Sub-division VIIIc East. The number of trawlers was reduced significantly in SD VIIIc East and West ( 45 to 34 and 61 to 44 , respectively). In Sub-division IXa South, there is an increase in the number of purse-seine vessels in the last two years, while in the multipurpose fleet the number of vessels and mean engine power has reduced. The fleets in all other areas showed some fluctuation, but were more or less stable. The following table summarises the structure of the Spanish fleet fishing for pelagic species in 1997:

| Sub-division | fleet type | n vessels | mean length (m) | mean engine power (HP) |
| :--- | :--- | :---: | :---: | :---: |
| VIIIc East | Artisanal | 583 | 7 | 47 |
|  | Gillnet | 38 | 13 | 144 |
|  | Hook | 304 | 12 | 136 |
|  | Purse seiner | 226 | 23 | 440 |
|  | Trawl | 34 | 23 | 425 |
| VIIIc West | Artisanal | 1311 | 6 | 28 |
|  | Gillnet | 67 | 14 | 152 |
|  | Hook | 239 | 16 | 214 |
|  | Purse seiner | 107 | 14 | 194 |
|  | Trawl | 44 | 26 | 516 |
| IXa North | Artisanal | 6027 | 5 | 22 |
|  | Gillnet | 1 | 9 | 51 |
|  | Hook | 152 | 20 | 358 |
|  | Purse seiner | 187 | 13 | 176 |
|  | Trawi | 105 | 24 | 435 |
| IXa South | Multi purpose | 54 | 11 | 134 |
|  | (Trawl+Artisanal) |  |  |  |
|  | Purse seiner | 79 | 14 | 257 |

### 1.8 Future Research

The Working Group is aware that a number of research programmes are being carried out at different laboratories which may in the immediate future be of assistance to the various assessments. It is important that the results of these investigations should be made available as soon as possible to the Working Group and that the Working Group should be kept informed of the progress in these programmes.

Some of the programmes which are of particular interest are:

- The exploratory fishing programmes being carried out on chartered commercial vessels by Faroe Islands, Norway and Russia that are aimed at obtaining information on the summer distribution of mackerel throughout Sub-areas V and II.
- The programmes, being carried out by Russia, using commercial aircraft and information from satellites, on the migrations of mackerel shoals.
- The final results of the EU-funded mackerel tagging project.
- Investigations being carried out by CEFAS and AZTI on the relationship between environmental conditions (water temperature and wind speed and directions) and recruitment.
- Discard levels of mackerel in the purse-seine fleets are being studied in a joint Norwegian, UK (Scotland) programme.
- Norwegian studies on genetic differentiation of Atlantic spawning stocks of mackerel are continuing.
- A new project on mackerel recruitment, entitled SEAMAR (Shelf Edge Advection, Mortality, and Recruitment), coordinated by England will start on $1 / 1 / 99$. This project is aimed at modelling larval survival through to recruitment.
- Scotland and Norway are planning acoustic surveys on mackerel in the fourth quarter in the Northern North Sea. These surveys may be able to produce an SSB index for mackerel for years in-between those in which the egg surveys are carried out and so could be vital in reducing the risk inherent in having an SSB value only once every three years.
- A new project (AIR CT 97-3374) is currently being carried out by the institutes of AZTI, IEO, IFREMER and IPIMAR on the ecology of juveniles of pelagic species (mainly anchovy and sardine). This project entitled "Experimental Surveys for Assessment of Juveniles" will provide a better understanding of the ecology and spatial distribution of the juveniles of these species in autumn time in Sub-areas VII, VIII and IX.
- Surveys, aimed at studying the abundance and distribution of juvenile mackerel in and around the "Cornwall Box", will be carried out by the UK in the winter of 1998/1999.

### 2.1 ACFM Advice and Management Applicable to 1997 and 1998

The TACs agreed by the various management authorities and the advice given by ACFM for 1997 and 1998 were as follows:

|  | 1997 |  | 1998 |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Stock | $\begin{array}{l}\text { Advice recommended } \\ \text { by ACFM }\end{array}$ | Agreed TAC | Catch | $\begin{array}{l}\text { ACFM: } \\ \text { tabulated } \\ \text { wighest } \\ \text { option }\end{array}$ | Agreed TAC |
| precautionary |  |  |  |  |  |$]$

${ }^{1}$ Assumed to be mainly Western stock mackerel, taken from Sub-area IV, Division IIIa and IIa, and included in the total agreed TAC for the western stock.
${ }^{2}$ Division VIIIc, Sub-areas IX and $X$ and CECAF Division 34.1.1 (EU waters only).
The agreed TAC for 1997 for all stocks combined amounts to $470,205 \mathrm{t}$, and that for 1998 to $549,335 \mathrm{t}$. Both these figures include the agreements between EU, Norway and the Faroes, and agreements that the Faroes has with Iceland, Estonia and Russia. The agreement with Russia is a by-catch quota.

For 1997 ACFM recommended a significant reduction in fishing mortality in order to restore and maintain the SSB within the range observed in the time series available. For 1998, ACFM recommended a fishing mortality between 0.15 and 0.20 , the highest tabulated F consistent with the precautionary approach was given as $0.8 \mathrm{~F}_{97}$.

It is again important to stress that while the TAC options are meant to apply to the total catch of all mackerel over the total distribution area the actual agreed TACs do not apply to the catches taken in international waters. The total catches in international waters, which are mainly taken by Russia in the Norwegian Sea, have been increasing in recent years. In 1998, the Russian catch in Faroese and international waters is at the same level as in recent years. There are no restrictions on the amount of fish which can be taken in the fishery in international waters.

In addition to the TACs and the national quota the following are some of the more important additional management measures which were in force in 1997 and are again in force in 1998. These measures are mainly designed to afford maximum protection to the North Sea stock while it remains in its present depleted state while at the same time allowing fishing on the western stock while it is present in the North Sea.

1. Prohibition of fishing in Division IVa during Quarters 1 and 2, and of a directed mackerel fishery in Divisions IVb and IVe throughout the year (Norway opened for a fishery in Division IVa the first half of the year since 1996);
2. Prohibition of a directed mackerel fishery in the "Mackerel Box";
3. Minimum landing size of 30 cm for Sub-area IV, Division IIIa and 20 cm for Divisions VIIIc and IXa;

Various national measures such as closed seasons and boat quotas are also in operations in most of the major mackerel catching countries.

### 2.2 The Fishery in 1997

### 2.2.1 $\quad$ Species mixing

## Scomber sp.

As in previous years, there was both a Spanish and a Portuguese fishery for Spanish mackerel, Scomber japonicus, in the south of Division VIIIb, in Division VIIIc and Division IXa.

Table 2.2.1.1 shows the Spanish landings by Sub-division in the period 1982-1997. In 1997 the catch in Division VIIlb was 362 t , a fall with respect to 1996. The catch in Sub-division VIIIc East reached $4,416 \mathrm{t}$ in 1997, being the highest
catch registered since 1982. In Sub-division VIIIc West the catch was 610 t , an increase with respect to 1996. In Subdivision IXa North in 1997, the catch fell (1,727 t) compared with the period 1993-1997.

Data of monthly landings by gear and area were obtained from fishing vessel owner's associations and fishermen's associations through the existing information network of the IEO and AZTI (Advisory Organisations to Fisheries and Oceanography Administration) in all ports of the Cantabrian and Galician ports. In the ports of Cantabria and Northern Galicia (Sub-division VIIIc West) catches of S. scombrus and S. japonicus are separated by species, since each of them is important in a certain season of the year. In the ports of Southern Galicia (Sub-division IXa North) the separation of the catch of the two species is not registered in all the ports, for which reason the total separation of the catch is made based on the monthly percentages of the ports in which they are separated and based on the samplings carried out on the ports of this area.

In Sub-division IXa South, the Gulf of Cadiz, there is a small Spanish fishery for mixed mackerel species which had a catch of 613 t of Spanish mackerel in 1997. In the bottom trawl surveys carried out in the Gulf of Cadiz in 1997, catches of S. Scombrus were scarce or even non-existent, with S. japonicus making up $99 \%$ of the total catch in weight of both species (M. Millán, pers. comm). Due to the uncertainties as to the proportion of S. Scombrus in landings, they have never been included in the mackerel catches reported to this Working Group by Spain.

In Portugal the landings of Spanish mackerel from Division IXa (CN, CS and S) were 5,408 t in 1997, more abundant in the southern areas than those of the north (Table 2.2.1.1). These species are landed by all fleets but the purse seiners accounted for $73 \%$ of total weight. Landings data are collected from the auction market system and sent to the Gencral Directorate for Fisheries where they are compiled. This includes information on the landings per species by day and vessel.

There is believed to be little error in the identification of mackerel species in the Spanish and Portuguese fisheries in Divisions VIIIb,c and in Division IXa.

The catches of the Scomber japonicus are not included in the TAC of the Scomber scombrus for the Southern area.

### 2.2.2 Catch estimates

The total catch estimated by the Working Group to have been taken from the various areas is shown in Table 2.2.2.1. This table shows the development of the fisheries since 1969. The total catches per quarter sine 1990 are shown in the text table below. The total estimated catch in 1997 was about $569,500 \mathrm{t}$ which was approximately $5,000 \mathrm{t}$ higher than the catch taken in 1996 which was the lowest recorded from the fishery since 1973. The TACs set for 1997 for all areas for which TACs were agreed amounted to $470,205 \mathrm{t}$ (See Section 2.5.1.1.) The decrease in catches during 1996 and 1997 have been mainly due to the decrease in the TACs set as a result of the international agreements and the more effective enforcement of the management measures. The corresponding TAC agreed for 1998 is $549,335 \mathrm{t}$. Estimates of discards are also shown in this table but these estimates apply to one fleet only.

During 1997 the highest catches (over $227,000 \mathrm{t}$ ) were again taken from Sub-area IV and Division IIIa - over 215,700 t of these having been taken in Division IVa. The catches taken from Division IIa and Divisions Va and Vb $(105,000 \mathrm{t})$ where the international fisheries take place were very similar to those recorded in 1996. The overall catch taken in the fisheries in Sub-areas VI and VII and in Divisions VIIa,b,de was $196,000 \mathrm{t}$ compared to 213,000 t in 1996. However, there was a considerable decrease in the catches from Division VIa where the catch fell from 130,000t in 1996 to $67,000 \mathrm{t}$ in 1997. This decrease was mainly recorded by Ireland ( $-10,000 \mathrm{t}$ ), Scotland ( $-13,000 \mathrm{t}$ ), France ( $-7,000 \mathrm{t}$ ), and in the unallocated catches $(-9,500 t)$.There was a corresponding increase in the catch in Division VII where the catch increased from $80,000 \mathrm{t}$ in 1996 to over $114,000 \mathrm{t}$ in 1997. This increase in total catch was reflected throughout all the main fishing divisions in Sub area VII.

The catches taken in Divisions VIIIc and IXa have slowly increased in recent years and the 1997 catch of over 40,700 t continued this trend and is the highest recorded since 1977. The amounts of catch misreported during 1997 was about $72,000 \mathrm{t}$ compared with $52,000 \mathrm{t}$ in the previous ycar. These catches were mainly taken in Division IVa but were reported as having been taken in Division VIa. Catches from the fishery in the southern part of Division VIa which had developed considerably in recent years decreased in 1997 and fell from $20,000 \mathrm{t}$ in the mid nineties to $15,000 \mathrm{t}$ in 1997.

The catches per quarter and per Sub-area and by Division are shown in Table 2.2.2.1 and also in Figures 2.7.1.1 to 2.7.1.4.

The quarterly distribution of the fisheries in 1997 was very similar to that of 1995 and 1996 . Over $34 \%$ of the total catch was taken during the 1st quarter as the shoals migrate through Sub-area VI to the main spawning areas in Sub-area VII.

Only $11 \%$ of the total catch was taken in Quarter 2, most of it from Sub-areas VI and VII. During Quarter 3 the main catches (33\%)were recorded from Division IIa and Division IVa from the shoals on the summer feeding' areas. During Quarter 4 the main catches ( $22 \%$ ) were recorded from the overwintering areas in Divisions IVa and IVa. The main catches from Division VIIIc ( $88 \%$ ) of the total for the division were taken in Quarter 1 and 2. Catches from Division IXa were evenly distributed throughout the year.

The quarterly distributions of the catches since 1990 are shown in the table below There appears to have been an important but gradual changes in the timing of the fisheries.

Percentage distribution of the total catches from 1990-1997

| Year | Q1 | Q2 | Q3 | Q4 |
| :--- | :--- | :--- | :--- | :--- |
| 1990 | 28 | 6 | 26 | 40 |
| 1991 | 38 | 5 | 25 | 32 |
| 1992 | 34 | 5 | 24 | 37 |
| 1993 | 29 | 7 | 25 | 39 |
| 1994 | 32 | 6 | 28 | 34 |
| 1995 | 37 | 8 | 27 | 28 |
| 1996 | 37 | 8 | 32 | 23 |
| 1997 | 34 | 11 | 33 | 22 |

## National catches

The national catches recorded by the various countries for the different areas are shown in Table 2.2.2.2-2.2.2.5. As has been stated in previous reports these figures should not be used to study trends in national figures both because of the degree of misreporting, and because of the high "unallocated" catches recorded in some years due to some countries exceeding their quota. The main mackerel catching countries in recent years continue to be Norway, United Kingdom, Ireland, Netherlands and Russia.

The total catch recorded from Divisions IIa and Vb (Table 2.2.2.2) was believed to be about $105,500 \mathrm{t}$, which was very similar to that for 1996 ( $104,000 \mathrm{t}$ ). Most of this catch was taken by Norway and Russia. The total catch believed to have been taken from "international waters" in this area for 1997 was about $55,000 \mathrm{t}$. High levels of misreporting were recorded in 1994 ( $109,600 \mathrm{t}$ ) between Divisions IVa and Division Ila. However, there appears to have been little misreporting in recent yeas from these areas although there is no data to support this assumption.

The total catch recorded from the North Sea (Sub-area IV and Division IIIa) (Table 2.2.2.3) was $227,600 \mathrm{t}$ compared with $212,800 \mathrm{t}$ in 1996. About $73,500 \mathrm{t}$ were believed to have been taken in Division IVa but were reported as having been taken in Division VIa. The main catches were recorded by Norway $(96,3001$ ), while substantial catches, totalling were also recorded by Denmark ( $22,000 \mathrm{t}$ ) and the United Kingdom ( $19,000 \mathrm{t}$ ).

The total catch estimated from the Western areas (Table 2.2.2.4) was $195,820 \mathrm{t}$, after corrections for unallocated and misreported catches (minus $69,000 \mathrm{t}$ ). The unallocated, misreported catches and discards are mainly made up of an unallocated catch of approximately $4,600 \mathrm{t}$ together with catches of about $73,500 \mathrm{t}$ believed to have been taken in Division IVa. The national catches have been very stable for a number of ycars - the main catches being recorded by the United Kingdom ( $129,000 \mathrm{t}$ ), Ireland ( $53,000 \mathrm{t}$ ) and the Netherlands $(28,000 \mathrm{t})$.

The total catch recorded from Divisions VIIIc and IXa (Table 2.2.2.5) was $40,700 \mathrm{t}$ which is the highest total recorded since before 1977 and continues the increasing trend in catches from this area observed in recent years. The TAC for 1997 was $30,000 \mathrm{t}$ while that for 1998 was $35,000 \mathrm{t}$. The increased catches were as a result of increased prices for mackerel and the increased effort by the Spanish fleet on mackerel in Division VIIc (east) caused by the collapse in the anchovy fishery. Most of the catch from this area is taken by Spain ( $>90 \%$ ).

### 2.2.3 Estimates of discards

At present only one country - the Netherlands - is providing information on discards but this information is not applied to any other fleets.

Information on discarding by the Dutch fleet is obtained from part ( $15-20 \%$ ) of the pelagic fleet which is regarded to be representative for all areas and months where the pelagic fleet is operating (see also Section 1.7 on fleet description). Estimates on discards are not made by independent observers of the fishery activities, but the crew collects information
during each trip per haul concerning date, position, trawl duration, catch composition by species. This estimation of the catch of each haul is done at the time the catch is taken on board (before any discarding takes place). If a catch is lost by torn nets, it is also reported. The information on species composition of the catch is added later. Finally the information on discards is obtained by comparing catch and actual reported landings. This discard information by species is then applied only to the whole Dutch pelagic fleet by month and by ICES Division, but not to the international fleet. This report contains a number of tables in which catches and discards are reported on an annual basis, but not on a quarterly basis (however, the basic discard data are available by month and by ICES Division).

General information on discards in the pelagic fleets is provided in Section 1.4.3.

### 2.3 Stock Units

The results of two new studies were made available to the Working Group. One concerned the results of an EU funded tagging programme for juvenile and adult mackerel (WD Uriarte et al. 1998). The other concerned the results of a genetic study into the different stock components in the NEA mackerel (WD Nesbø 1998). In summary, Uriarte et al. concluded that the western and southern components were not functionally separate as fish tagged in the southern area could be recaptured in the western area. Nesbø concluded that the southern stock was older, more genetically diverse and separate to the western stock. This conflict needs to be resolved. Confirmation of the genetic studies should be considered with further and more standardised sampling, probably associated to a triennial egg survey. The Nesbø study was based on examples from the centres of the areas, and so could not describe where the genetic groups stopped and the next started. The Uriarte et al. study showed that fish from the southern area could migrate to the Norwegian Sea and back. One possible synthesis is that the components, if they exist, might be genetically different but that their behaviour is largely identical. For the southern and western components to exist there must be some homing behaviour and by now it is known that they follow the same migration path, and are mostly caught in the same fisheries. Furthermore, if the two components exist, neither the genetic nor the tagging studies allow any definition of boundaries between these components.

The Working Group agreed that work on tagging and genetics should continue as the exact definition of the status of these stock components remains an important subject.

### 2.3.1 Tagging information

Between the early 70s and 1995 several tagging experiments on mackerel (Eaton 1980, Hamrc 1980, Rankine and Walsh 1982, Bakken and Westgard 1986, Iversen and Skagen 1989, Uriarte and Lucio 1996, in press) have demonstrated that mackerel from all spawning areas (North Sea, western and southern areas) migrate to the North of Europe up to Divisions IIa and IVa where they mix for the second half of the year. Uriarte and Lucio (op.cit.) (SEFOS project, AIR92-CT1905) demonstrated that the adult mackerel visiting the southern area are adults coming from the western area which continue their spawning migration through Division VIIIc before going back to the North (see Section 13.3.3 for further information and figure 13.3.3.1).

Recently, in 1997, a new international study project on the migration of both adult and young mackerel has been carricd out by Portugal (IPIMAR), Spain (IEO and AZTI), Ireland (MI) and Norway (IMR) (Uriarte at al. WD 1998). This project entitled: "Spatial Pattern of migration and recruitment of North east Atlantic mackerel" (EU Study project contract $96-$ 035) has the objectives of clarifying the migration pattern of adult mackerel from the southern and western areas and of determining the spatial pattern of juvenile recruitment from two nursery areas: the Northwest of Ireland and West of the Iberian Peninsula. A total of 119,913 mackerel were tagged along the European Atlantic coasts: 83,514 adults at the spawning time in western and southern areas and 36,399 of juveniles at different times of the year (Figure 13.3.2.2). The preliminary results of this study up to December 1997 concerning adults and juveniles are presented in Figure 13.3.2.3 and 13.3.2.4 respectively.

The preliminary conclusions derived from these Project 96/035 results are:
a) Adult mackerel from all the southern area (Division VIIIc) appear to join the general Migration of mackerel to the North of Europe during the second half of the year with the rest of the Northeast Atlantic population. This finding confirms the conclusions of the previous tagging experiment performed in 1994 in the Southern area, at the east of Sub-division VIIIc east (Uriarte and Lucio, op.cit).
b) Adult mackerel spawning in the western area moved at the end of summer and early autumn into the Norwegian Sea and northern part of the North Sea. This finding is congruent with the observations made for years by the IMR of strong entry of western mackerel into these areas in late summer (Iversen and Skagen 1989).
c) In contrast, young mackerel (both from the west of the Iberian peninsula and from the northwest of Ireland) seem to remain all close to the places where they were tagged.

From the tagging experiments performed on the spawners of the southern area in 1994 and 1997 several recoveries have been produced during spring time in the western spawning grounds. Most of the recoveries come, however, from the Northern areas reflecting probably the larger fishing effort recorded in those areas compared to the southern ones. It seems that adults from the southern and westem areas have always been caught together.

Concerning the definitions of stocks, the tagging experiments suggest that there is mixing between southern and western components. No clear evidence of the homing behaviour can be obtained from the results obtained up to now. The conception of southern and western components is not inferred from the tagging data.

### 2.3.2 Genetic studies

One new piece of work on genetic differentiation of mackerel stocks was presented at this meeting (WD 1998 Nesbø). This WD was based on work on mitochondrial DNA, specifically, the cytochrome $b$ gene and on the D-loop region. The preliminary conclusion was that four genetically different spawning populations can be defined; western, southern, North Sea and Mediterranean. It is suggested that this differentiation occurred after the last glaciation period, some 10,000 years ago. One implication from this is that as the North Sea stock is genetically different, the stock is likely to have to recover from collapse without recruitment from the western stock. A second implication is that it should be possible to study the mackerel found in the North Sea, both juvenile and adult to determine the current spatial distribution and the split between genuine North Sea stock and transients from the western stock. Perhaps most importantly, the impact of fishing on adult mackercl in IV a could be more precisely targeted to reduce the impact on the North Sea stock.

This work is very promising and should be encouraged.

### 2.3.3 Allocation of catches to stock

Since 1987 all catches taken in the North Sea and Division HI have been assumed to belong to the Western stock. This assumption also applies to all the catches taken in the international waters. It has not been possible to calculate the total catch taken from the North Sca stock component separately but it has been assumed to be $10,000 \mathrm{t}$ for a number of years. This is because of the very low stock size and because of the low catches taken from Divisions IVb,c. This figure was originally based on a comparison of the age compositions of the spawning stock calculated at the time of the North Sea egg surveys This assumption has been continued in 1997 but it should be pointed out that if the North Sea stock should increase, then the figure may need to be reviewed. An international cgg survey carried out in the North Sea during June 1996 provided a very low index of stock size in the area. A further egg survey in the North Sea is planned for 1999 and should give additional information on the state of the stock.

Prior to 1995 catches from Divisions VIIIc and IXa were all considered to belong to the southern mackerel stock, although no assessment had been carried out on the stock. In 1995 a combined assessment was carried out in which all catches from all areas were combined, i.e. the catches from the southern stock were combined with those from the western stock. The same procedure was carried out by the 1997 Working Group and again by the present Working Group - the new population unit again being called the North-east Atlantic mackerel unit.

The TAC for the Southern area applies to Divisions VIIIc and IXa. Since 1990, 3,000 t of this TAC, which has been fixed at $30,000 \mathrm{t}$, has been permitted to be taken from Division VIIIb in Spanish waters. This area is included in the "Western" management area. These catches ( $3,000 \mathrm{t}$ ) have always been included by the Working Group in the western component and are therefore included in the assessment for the Western area.

### 2.4 Biological Data

### 2.4.1 Catch in numbers at age

The 1997 catches in numbers at age by quarter for NE Atlantic mackerel (Areas II, III, IV, V, VI, VII, VIII and IX) are shown in Table 2.4.1.1. The percentage catch by numbers at age is given in Table 2.4.1.2.

The age structure of the catches of NE Atlantic mackerel is predominantly $1-6$ year old fish. These age groups constitute $82 \%$ of the total catches. The 1993 year class ( 4 year old fish) dominated the catches throughout half of the arcas where mackerel was caught. Fish belonging to the 1996 year class were dominant in the catches in Q3 Division VIa. In other areas the catches were dominated by young fish; in IVb, IVc and VIIh catches were dominated by 1 year old fish; in

VIId, and VIIe,f catches were dominated by 2 year olds; and VIIg catches were dominated by and 2 and 3 year old fish. Catches from Divisions IXa were again dominated by 0 and 1 group fish in 1997. This continues the trend of greater relative abundance of these age groups in the catch since $1995(24 \%, 44 \%$ and $80 \%$ respectively). In VIIIc east the catches were predominantly age group 4-5 fish, while in VIIIc west $50 \%$ of the catch were age group 2 fish.

Age distributions of catches were provided by Denmark, England, Ireland, Netherlands, Norway, Portugal, Russia, Scotland and Spain. There are still major gaps in the overall sampling for age from countries which take substantial catches, notably Faroes, France, Germany and Sweden (combined catch of $52,156 \mathrm{t}$ ). In addition there were no aged samples to cover the entire catch from VIIa, VIIg, VIIk and Va (total catch 528 t). As in 1997, catches for which there were no sampling data were converted into numbers at age using data from the most appropriate fleets. This is obviously undesirable where the only aged samples available are from a different type of gear. The description of the allocation of age structures to unsampled catches is described in Molloy and Kelly (WD 1998).

Sampling data are further discussed in Section 1.4.1.

### 2.4.2 Length composition by fleet and country

Length distributions of some of the 1997 catches by some of the fleets were provided by England, Ireland, Netherlands, Norway, Portugal, Scotland, Spain and Russia. The length distributions were available from most of the fishing fleets and account for about $90 \%$ of the official catches. These distributions are only intended to give a very rough indication of the size of mackerel by the various fleets and do not reflect the seasonal variations, which occur in many of the landings. More detailed information on a quarterly basis is available for some fleets on the Working Group files. The length distributions by country and fleet for 1997 are shown in Table 2.4.2.1.

### 2.4.3 Mean lengths at age and mean weights at age

## Mean lengths

The mean lengths at age per quarter for 1997 for the NE Atlantic are shown in Table 2.4.3.1. These data continue the long time series and may be useful in investigating changes in relation to stock size.

## Mean weights

The mean weights at age in the catch per quarter and ICES Division for NE Atlantic mackerel in 1997 are shown in Table 2.4.3.2. Mean weights at age in the stock at spawning time for NE Atlantic mackerel are based on a weighted mean of the stock weights for the Western, Southern and North Sea stock components, with the exception of age group 1, which is based on a constant value used since 1988. The stock weights for NE Atlantic mackerel and the Western, Southern and North sea components are given in Table 2.4.3.3.

### 2.4.4 Maturity ogive

The maturity ogives for the North East Allantic mackerel were obtained as averages weighted by the relative proportion of the egg production spawning stock biomass within the respective areas. Thus, for combining the western, southern and North Sea stock data, weighting factors of $0.825,0.125$ and 0.025 respectively were applied. The maturity ogives for the three different stocks and for the North East Atlantic mackerel are given in Table 2.4.4.1.

Maturity at age is constant for each year of assessment. However, it is important for assessment purposes that the maturity ogive represents the proportions of fish by age group that actually spawn, because the assessment is tuned to the SSB obtained from egg surveys. Therefore an estimation of the maturity ogive in 1998 will be obtained as part of the egg survey of the western and southern area (ICES 1997/H:4). In this context samples have been taken over areas of predominantly juvenile distribution as well as on the spawning grounds (see also Section 3.2.1.3). Samples will be analysed by histological examination to provide a more accurate estimate of the numbers of fish which will actually spawn in that year. Results will become available at next year's Working Groups meeting.

### 2.4.5 Natural mortality and the proportions of $F$ and $M$ before spawning

The value for natural mortality used by the Working Group for all components of the NE Atlantic mackerel stock is 0.15 . This estimate agrees with the value obtained from Norwegian tagging studies carried out in the North Sea (Hamre 1978). The proportion of F and M before spawning for NE Atlantic mackerel is taken as 0.4 while for the Western Stock value is 0.4 .

### 2.5 Fishery Independent Information

### 2.5.1 Long-term tagging studies to estimate mortality

No new information was presented at the Working Group meeting this year. Given the small amount of fishcryindependent information the Working Group considers that these studies are valuable and should be continued.

### 2.5.2 Egg surveys

The historic time series of stage 1 egg production and SSB estimates, for the western area from 1977 to 1995, was updated at the Working Group in 1997 (Table 2.2.1 in ICES (1998/Assess:6)). No further changes have been made to that data set.

At the planning meeting in Lisbon, for the 1998 mackerel and horse mackerel egg surveys of the western and southern areas, the Working Group agreed that preliminary results of the 1998 egg surveys would not be available in time for either the current Assessment Working Group or for the October meeting of ACFM. Although some egg survey results might be available by the end of September, work on the analysis of the samples for fecundity, atresia and maturity at age would not be completed until carly in 1999. As a consequence only an incomplete set of egg survey results, from the western area only, is available from the 1998 egg survey (see Section 1.5). These data have not been subjected to a rigorous check and must therefore be regarded as not having undergone a complete analysis.

The following information, on egg distribution was available for the western area only.
In the first sampling period in the western area, period 3, egg production was high along the shelf edge from $53^{\circ} \mathrm{N}$ down to southern Biscay. The main concentrations of stage 1 eggs were found in the vicinity of the Great Sole and Little Sole Banks. The boundaries of the distribution were fairly well defined except at the northern edge, $53^{\circ} 15^{\prime} \mathrm{N}$, where stage 1 eggs occurred in five of the six sampled rectangles.

The peak of spawning occurred in the next period, period 4, and was concentrated very tightly along the shelf edge from the Butt of Lewis ( $58^{\circ} \mathrm{N}$ ) to southern Biscay. Egg production throughout that area was evenly spread with no clearly identifiable major concentration. The boundaries of the distribution were well defined south of the Porcupine Bank area. To the north of this area the western edge was less well defined although there were no very high counts along this edge.

Spawning declined in period 5, although the samples taken from central Biscay southwards have not yet been analysed. Stage 1 eggs were found all the way south from the Butt of Lewis. They were concentrated along the shelf edge south of Ireland and to the west, off the shelf edge, west of Ireland and northwards. As in the previous period the boundaries of the distribution were less well defined to the north of the Porcupine Bank. There were some high numbers of stage 1 eggs well off the shelf edge along the western boundary of the sampled area and also at one station at the northern edge of the survey area.

Spawning had declined further in the final sampling period, period 6, although again the samples taken from central Biscay southwards have not yet been analysed. Production was concentrated on the shelf south of Ireland and into the Celtic Sea whilst from north-west of Ireland and northwards the production was to the west of the shelf edge. The boundaries of the distribution were fairly well defined south of $55^{\circ} \mathrm{N}$ but to the north along the western and northern edges of the sampled area high egg counts were found. Stage 1 eggs were also found in five of the six sampled rectangles at $59^{\circ} 15^{\prime} \mathrm{N}$, to the north of the standard sampling area.

The preliminary estimate of total stage 1 egg production in the western area, from the samples analysed to date, is approximately $15 \%$ lower than the production measured in 1995. Because some of the samples have not yet been analysed, this is likely to be an under-estimate of total production.

No data on mackerel egg production in the southern arca were available at the Working Group.

### 2.5.3 Winter acoustic surveys for mackerel

## The surveys

In recent years a series of echosounder and sonar surveys have been carried out to study the mackerel during this period. Two of these were carried out by IMR Bergen and two by MLA. A working paper on one of the IMR surveys was presented to the Working Group in 1997 (Misund WD 1997) and on one of the MLA surveys in 1998 (Reid WD 1998). All four surveys were successful in locating and surveying the stock concentration, although in all cases it was
concluded that the surveys had probably not covered the whole stock. It should be emphasised that these surveys were designed for research purposes and not for abundance estimation. A partial stock estimate of 1.6 million tonnes was calculated for the MLA survey in 1995, and preliminary analyses suggest a similar biomass for the IMR 1996 survey.

## Problems

There are a few problems to be expected in conducting acoustic surveys on this stock at this time. Most importantly, mackerel has no swim bladder, and so has a relatively low target strength (TS). The presence of other fish with swim bladders (e.g. herring) in any numbers will complicate the analysis as these will tend to dominate the acoustic return. Further the precise TS is poorly established, and so absolute abundance estimation will be difficult. Another problem is the weather in this area at this time of year which is often severe. It would also be useful if the global distribution of mackerel beyond the specified area could be documented for this time of year.

## Advantages

Assuming that the problems described above can be overcome, there are a number of major advantages to this type of survey. These surveys can be carried out in a relatively short time (the MLA surveys lasted two weeks) and at a time of year when research vessels are under less intense pressure. They can thus be carried out on an annual basis. Acoustic surveys include trawling. As a result the stock estimate would also be available in age disaggregated form. Acoustic surveys would be best carried out in the years between the egg surveys.

### 2.5.4 Trawl surveys for juvenile mackerel (mackerel recruit indices)

Once again the traditional mackerel recruit index for mackerel has not been calculated. This is due to consistent doubts about the performance of the index which has shown an upward trend in recent years in relation to the recruitment calculated from the assessment (ICES 1998/Assess:6). A new analysis approach has been developed using Generalised Additive Modelling (GAM) described in Section 2.8. which show considerable promise. The recruit distributions are presented in Section 2.7.2.

As noted in last year's report (ICES 1998/Assess:6) it continues to be important that these surveys be continued. Poor coverage in 1997/98 has made it difficult to follow trends and may also be detrimental to the utility of the GAM based analysis. The results from these surveys are the only available source of data on juvenite distributions, and this forms a significant part of the advice requested from this Working Group to NEAFC (see Section 13).

### 2.6 Effort and Catch per Unit Effort

## Commercial CPUE

The catch-per-unit- effort is only provided for the southern area.
Table 2.6.1.1 and Figure 2.6.1.1 show the fishing effort data from Spanish and Portuguese commercial fleets. The table includes Spanish effort of the hand-line fleets from Santona and Santander (Sub-division VIllc East) from 1989 to 1997 and from 1990 to 1997 respectively, for which mackerel is the target species from March to May. Table 2.6.1.1 and Figure 2.6.1.1 also show the effort of the Aviles and La Coruña trawl fleets (Sub-division VIIIc East and VIIfc West) from 1983 to 1997 and the Vigo purse-seine fleet (Sub-division IXa North) from 1983 to 1992 for which mackerel is a by-catch. The Spanish trawl fleet effort corresponds to the total annual effort of the fleet for which demersal species is the main target. Portuguese mackerel effort from the trawl fleet (Sub-division IXa Central-North, Central-South and South) during 1988-1997 is also included and as in Spain mackerel is a by-catch.

Table 2.6.1.2 and Figure 2.6.1.2 show CPUE corresponding to the fleets referred to in Table 3.3.3.1. The Spanish trawl fleets in 1997 showed an increase compared with the ones from 1996, as well as the hand-line fleets. The Portuguese trawl fleet CPUE decreased from 1996 to 1997.

Catch-per-unit-effort, expressed as the numbers fish at each age group, for the various fleets is shown in Table 2.6.1.3.

### 2.7 Distribution of Mackerel

### 2.7.1 Distribution of commercial catches for mackere]

The distribution of the mackerel catches taken in 1997 is shown by quarter and rectangle in Figures 2.7.1.1-4. These data are based on catches reported by Portugal, Spain, Netherlands, Germany, Denmark, Norway, Sweden, Russia, Faroes, UK and Ireland. In these data the Spanish and Portuguese catches are not based on official data.

## First Quarter 1997

Catches during this quarter totalled about $187,000 \mathrm{t}$. There was again evidence of misreporting between Divisions IVa and VIa, with large catches west of $4^{\circ} \mathrm{W}$. Again the split between these two areas should be treated with caution. The general distribution of catches was similar to 1996 and 1995 suggesting that the pattern and timing of the pre-spawning migration remains constant. Slightly more catches were apparently taken in the English channel area in 1997 than 1996. The catch distribution is shown in Figure 2.7.1.1.

## Second Quarter 1997

Catches during this quarter totalled about $61,700 \mathrm{t}$, up on 1996. The general distribution of catches was similar to 1996. The main catches being taken east of Faroe, SW of Ireland and around the Iberian peninsula. The catch distribution is shown in Figure 2.7.1.2.

## Third Quarter 1997

Catches during this quarter totalled about $162,300 \mathrm{t}$. The general distribution of catches was similar to 1996 and 1995 . The main catch arcas were in the area west of Norway and in Faroese and international waters in the Norwegian Sea. The catch distribution is shown in Figure 2.7.1.3.

## Fourth Quarter 1997

Catches during this quarter totalled about $111,100 \mathrm{t}$. The general distribution of catches was similar to 1996 . The main catches were taken in the area west of Norway across to Shetland. Smaller catches were taken west of Scotland and Ireland and in the English Channel. There were some indications of more catches in the Cantabrian Sea. The catch distribution is shown in Figure 2.7.1.4.

### 2.7.2 Distribution of juvenile mackerel

## Surveys in winter 1997/98

## Fourth Quarter 1997

No data were available at this time for the North Sea or the Western Approaches for quarter 4 1997. In those areas covered, relatively low abundances were recorded for both 0 and 1 year old fish (Figures 2.7.2.1 and 2). West of Scotland and Ireland catch rates for age 0 were greatly reduced from 1996. The only area to maintain similar abundances to 1997 was off the north Portuguese coast.

## First Quarter 1998

As in the previous quarter catch rates were much lower than in 1997. Good catches of 1 year old fish were taken in the central North Sea, which was not seen in 1997. However, there was no evidence of the large numbers of the 1996 year class seen in the northern North Sea in this quarter in 1997. There were also good catches of 1 and 2 year old fish in the Cornwall area (Figures 2.7.2.3 and 4).

## Trends in survey results

Reduced survey effort makes it difficult to assess whether the trends in recruit survey data reported previously (ICES 1998/Assess:6) have been maintained. In quarter 4 there continues to be a "hot spot" near the Spanish-Portuguese border and catch rates west of Ireland and the Hebrides remain low. In quarter 1 there continue to be reasonable catches of age 1 fish in the North Sea, although not on the scale of 1997. Based on recent trends (ICES 1998/Assess:6), the low catch rates off Ireland and the Hebrides compared to the reasonable catches off Cornwall would suggest that 1997 will not prove to be a good recruitment year.

### 2.7.3 Distribution of spawning fish

There were strong indications from the 1998 mackerel egg surveys that the recent trend of a northwards extension of the spawning area was continuing. High densities of recently spawned eggs were found on the northernmost edge of the survey arca, at $58^{\circ} 15^{\prime} \mathrm{N}$, in June and spawning in that area continued into July.

The distribution of spawning at the start of the season, in March, continues to follow the historical pattern of a strong association with the shelf edge, with the highest concentrations in the vicinity of the Little Sole and Great Sole Banks.

By the end of April and in early May this pattern was still evident from southern Biscay to south-west of Ireland. To the north of this area there was extensive spawning over the Porcupine Bank and extending west off the shelf edge to the west of Scotland.

During June most of the spawning was from south-west of Ireland northwards with the major concentrations again over the Porcupine Bank and off the shelf edge west of Scotland, up to $58^{\circ} 15^{\prime} \mathrm{N}$.

At the end of the spawning period, in July, the northwards extension of the spawning area was still evident, with some spawning activity as far north as $59^{\circ} 15^{\prime} \mathrm{N}$. To the south of Ircland the spawning followed the typical pattern, spreading east from the shelf edge over the Celtic Sea. By July spawning was over in the whole of Biscay and along the Cantabrian coast.

The only data available at the Working Group on mackerel spawning in the southern area in 1998 were from surveys off the Cantabrian and Galician coasts in March and late April. Spawning in both periods was typically strongly associated with the narrow shelf with very little spawning beyond the 500 m depth contour.

### 2.7.4 Winter distributions from acoustic surveys

Recent acoustic surveys in the north-eastern part of the North Sea by Scotland and Norway in 1996 and 1997 have confirmed that the bulk of the western mackerel stay in this area from October to at least the end of December. Scottish and Netherlands surveys in January 1994 and 1995 indicate that the migration to the spawning areas then commenced in January. Recent reports from commercial vessels confirm that this pattern appears to have continued into 1998.

### 2.8 Recruitment Forecasting

In previous Working Groups doubt has been expressed about the value of the combined mackerel recruit index derived from the series of bottom trawl surveys in quarters 1 and 4 of each year (ICES 1996/Assess:7; ICES 1995/Assess:2). Evidence was presented (ICES 1997/Assess:3) that this might be explained by the more northerly distribution of the juvenile fish in recent years and it was recommended that further modelling studies be carried out to explore this possibility.

At the Working Group a comparison was made between the recruitment indices derived from the available survey series and the ICA estimates of recent recruitment at age 0 . Last year it was suggested that the fit between the assessment series and the Scottish west coast quarter 1 survey had broken down in 1997 (Figure 2.8.1.b); the survey index giving a very low estimate for the 1996 year class. The juvenile distribution maps (ICES 1998/Assess:6) showed a dramatic increase in age 1 fish in the northern North Sea and based on the assumption that these fish might belong to the Western "stock" rather than the North Sea "stock" they were then included in the west coast index, resulting in an improved fit to the VPA estimates from the catch at age data. Subsequent surveys from the Western area (Figure 2.8.1.c,d,e) have also indicated that the strength of the 1996 year class is below the average of recent years, but stronger than the weak year classes of 1972, 1977, 1982 and 1983. The indices are consistent at age 0 and age 1 . The A Coruña CPUE index for age 1 (Figure 2.8.1.f), which was used as an qualitative index in last year's assessment, also indicates a 1996 class equivalent to the mean of recent years. These indices are in contradiction to those recorded in the Southern area by the Portugal and Spanish October surveys, (Figure 2.8.1.g and h, Table 3.3.2.2.1). Both indicate that there has been an increased catch of the 1996 year class, although historically they have not followed the ICA time serics.

The survey indices show that the strength of the 1997 year class is close to the average of recent years.
The results of analyses carried out at this years meeting have established that there is a latitudinal drift in the centre of gravity of the catches of juvenile mackerel which is correlated with changes in water temperature. Higher temperatures being associated with a northward movement of the distribution of catches of the combined and individual survey components. The calculations assume that the geographic bounds of the areas covered by the surveys are relatively constant throughout the time series.

In order to establish whether this response could be used in a model for predicting year class abundance from trawl survey data, a two stage Generalised Additive Model (GAM, Hastie, T. and Tibshirani, R. 1990.) was fitted to the catch data for age group 0 . The model incorporated a lowess smoothed latitude-longitude surface for the position at which the catches are taken, a lowess smoothed annual temperature effect and separate responses for each of the surveys. In Stage 1 the model is fitted to binomial data, indicating whether a catch was recorded at a station, using a log link function
(McCullagh, P. and Nelder, J. A. 1983). In Stage 2 the stations at which catches were taken were modellcd with a Gamma error structure again with a log link.

The model results are presented graphically in Figures 2.8 .2 and 2.8.3. In both figures the upper left graph presents the year class effect, the upper right the survey effect, the lower left the latitude longitude surface and the lower right the smoothed temperature effect. The trawl survey labels ("count") are: 1 - the English March survey, 2 - the French September/October survey, 3 - the Ireland October/November survey, 4 - the Netherlands November/December survey, 5 - the Scottish March survey, 6 - the Scottish November/December survey. The GAM estimated upper and lower twice-standard-error curves are plotted as hashed lines for the year class, country and temperature effects.

The distance between the standard error lines indicates that the year class effects fitted by both models are poorly determined for the 1984, 1985 and 1986 cohorts and should not be used in any index series. Excluding those years, the year class effects for the probability of recording a catch are relatively constant throughout the time series, apart from the final year, for which only the English and Scottish 1st quarter surveys are currently available. These surveys have a higher probability of recording positive catches as is shown by the country effects (labelled 'count') in Figure 2.8.2.b. Encouragingly, the GAM latitude longitude surfaces for the two models reflect the known distribution of the age 0 fish, which are distributed in the areas of the Celtic Sea, West of Ireland and West of Scotland. As was established in the preliminary studies the catches and the probability of making a catch exhibit a positive correlation with sea temperature.

A combined survey index, calculated by multiplying together the exponents of the year class effects from the two stages, is presented in Figure 2.8 .4 along with the separable populations estimated by ICA at age 0 , for the same time period. The two series show fairly good agreement and give similar patterns for the 1996 and 1997 year classes to those seen in the individual survey results presented in Figure 2.8.1. The increasing trend noted in recent years for the indices derived from average catches appears to have been removed by the use of a sea temperature cffect.

Further developments of the model are planned. These include the use of temperature data for each individual survey and the addition of an index based on the age 1 catches. As noted in previous reports (ICES 1997/Assess:3) there appears to be a tendency in recent years for high catch rates to be taken at the extreme north and south ends of the range in good recruit years. There may be two possible explanations for this. First, that following a good recruit year the juvenile fish tend to spread out over a wider area, the so called "basin effect". Or secondly, that the conditions which lead to a good recruitment also tend to result in a greater transport of the young fish into the Hebrides area. Extensions of the GAM model would provide a method for exploring these scenarios.

The conclusion from these studies is that trawl indices could perhaps be used for modelling the recruitment to the mackerel stock if the influences of environmental conditions on this highly migratory species are taken into consideration. However, the range of years over which the survey indices can be calculated does not include the extreme variation observed in the 1970s and carly 1980s and the predictive power of the model is not tested at these levels. A requirement of the use of this form of model is the availability of temperature data for the months prior to, and at the time of the survcy. The collection of bottom trawl recruit data continues to be important in order to retain an appreciation of changes in juvenile distribution and their potential impact the predictions.

### 2.9 State of the Stock

### 2.9.1 Data exploration and preliminary modelling

Trial runs with the ICA were made to explore in particular the sensitivity to two kinds of model assumptions, the number of years with separable constraint, and the relative weighting of the SSB cstimates for the egg surveys, to the catches at age. The background for this is the problem that appears when the last catch-independent data point is far back in time. This provides litte information as to the recent development of the stock, the estimate of which relies entirely on how catch estimates derived with the assumed fishing pattern fit the actual catches. This fit is quite sensitive to deviations from the assumed selection pattern.

The ICA estimates of the stock numbers in the years of separablc constraint, is weakly influenced by information from previous years, when this is given as absolute measures of abundance. Reducing the number of years with separable constraint therefore also reduces the number of SSB data points that influence the calibration of the population matrix. Accordingly, as the number of years with separable constraint is reduced, the perception of the stock in recent years is increasingly dominated by the last data point. This is illustrated in Figure 2.9.1.1. In particular this is apparent when the number of years with separable constraint is reduced from 8 to 7 , by which the influence of the 1992 SSB estimate is lost.

The final stock estimate is a compromise between the signal given by the survey data and that given by the catches. The influence of each of these components can be scaled by the relative weight given to the survey data. This is illustrated in Figure 2.9.1.2. One possible alternative would be to weight the data according to the inverse estimated variance of the residuals. However, this variance estimate will reflect inconsistencies in the data more than how much faith one should put in the surveys compared to the combination of the catches and the separable assumption.

In ICA, there is an implicit weighting of each category of information, according to the number of data points that contribute to the objective function. The inclusion of another year of catch data therefore implies a downweighting of the survey data, in particular if the number of years with separable constraint is small. Therefore, keeping all model choices similar from year to year does not imply that all model assumptions are similar. As shown in Figure 2.9.1.2, the stock estimate for the recent years is very sensitive to the weighting of the survey data.

Given these sensitivity problems, the Working Group decided not to present a new analytical assessment until the SSB estimate from the 1998 egg survey data is ready. To provide an intermediate guidance for management, a simple projection of the 1997 Working Group stock estimate was made (Section 2.9.2).

Provisional ICA assessments were made with preliminary data for the 1998 egg survey for both the NEA mackerel and the Western mackerel. The results are presented in Tables 2.9.1.1-10 and 2.9.1.11-20 respectively. The diagnostic graphs are in Figures 2.9.1.3-6 and 2.9.1.7-10, respectively. These results indicate a reduction of SSB in recent years by about $10 \%$ compared to the assessment made last year. This number is still preliminary, and based on incomplete data, so this assessment should only be taken as a part of the exploratory runs, and as an indication of what to expect if the final result is similar to the preliminary one. The SSB estimates, together with the results of runs with similar model assumptions and the 1997 Working Group assessment are shown in Figures 2.9.1.11-12.

In both these runs, the estimated SSB in 1998 is very close to the SSB indicated by the egg survey. For previous years, the ICA estimate is generally below the egg estimates. This illustrates some of the conflict between the indications by the catches at age and the egg survey data. The further away the egg survey is, the more will the catches dominate the assessment for the last years, and these will tend to indicate a lower stock. This signal is weak, however, perhaps due to the poor contrasts in the catch at age matrix, so when there is a survey in the last year, the stock estimate will to a large extent be adapted to that value. The text table below, which shows the effect of upweighting and downweighting the survey information with and without the last survey data point, on the SSB-estimate in 1997, again illustrates this sensitivity problem.

|  | Survey weight $=0.1$ | Survey weight $=1$ | Survey weight $=10$ |
| :--- | :--- | :--- | :--- |
| 1998 egg est. included | 1235 | 2200 | 2390 |
| 1998 egg est. excluded | 621 | 2200 | 2920 |

SSB estimate in 1997 in thousand tonnes.

### 2.9.2 Stock assessment

No new assessment was carricd for reasons given in Section 2.9.1. The assessment on the North East Atlantic mackerel as carried out at last year's Working Group meeting was therefore used for assessment purposes. In order to be able to carry out catch predictions (Section 2.10) the starting numbers at age in the population on the first of January 1998 were projected from the numbers at age on first of January 1997 by using the catch numbers at age of 1997. The separable fishery pattern for 1996 from last year's ICA was then tuned to such a level that the SOPs corresponded to the catch of 1997 ( $570,000 \mathrm{t}$ ) as shown in the text table below. The calculated $\mathrm{F}(4-8)$ from these rescaled fishing mortalities is estimated at 0.22 .

| Age | N pop. 1/1/97 | catch 1997 | F calc. | N 1/1/98 | F = F-pattern of 1996 |
| :--- | :---: | :---: | :---: | :---: | :---: |
| 0 | 3872 | 36.01 | 0.010 | - | 0.0063 |

| 11 | 86 | 13.95 | 0.191 | 167.1 | 0.2593 |
| $12+$ | 161 | 24.97 | 0.182 | 228.2 | 0.2593 |
|  |  |  |  |  |  |
|  |  | SSB=2530 kt | catch 570 kt |  | $\mathrm{SSB}=2660 \mathrm{kt}$ |

### 2.9.3 Reliability of the assessment and uncertainty information

In addition to the modelling problems that have been described in Section 2.9.1, some other sources of uncertainty should be pointed out.

The assessment relies heavily on the catch data, and in particular the age structure of the catches. In this respect, it is problematic that a fairly large proportion of the total catch volume has to be distributed by age based on a small number of samples from the fisheries in question, as discussed in Section 1.4.1. Moreover, there is sparse information about underreporting, slipping and discards. Since the stock abundance estimate is calibrated using absolute SSB-values for recent years, and with a VPA for previous years, underestimation of the catches will tend to lead to overestimation of the stock in recent years and underestimation in earlier years. In this respect, one should note that the estimate of the SSB is below the egg survey estimates in most previous years. The finding that it almost hits the egg cstimate for 1998 may be due to this. This result is highly sensitive to the relative weighting of the survey data, however.

The more general problem is that of doing an assessment with very sparse supplementary data. In a previous Working Group (ICES 1997/Assess:3), simpler models using SSB estimates from egg surveys and mortality estimates from tagging data were explored. Although such models leave out much of the detailed information in the age-disaggregated data, they may be more robust with respect to overall trends in the state of the stock. These trends are not very different from those of the ICA assessment. Thus, despite the difficulties encountered in the present attempt to assess the stock, the Working Group considers it unlikely that the perception of the present state of the stock, and of the trend in recent years is likely to be grossly misleading.

The provisional runs using the preliminary SSB estimate from the 1998 egg survey, gave an estimate of the SSB in 1998 slightly below the projected value starting with the 1997 assessment (see Section 2.9:1), and very close to the actual survey cstimate of SSB. As pointed out in Section 2.9.1, this result is strongly dependent on the relative weighting of the survey data, however.

A more formal uncertainty cstimation will be attempted when a new egg survey estimate is finalised.

### 2.10 Catch Predictions

Table 2.10.1 presents the input values for the catch forecasts.
The starting numbers at age in the population on the first of January 1998 are a projection from the numbers at age on first of January 1997 by using the catch numbers at age of 1997 , because no new assessment was carried out at this meeting (sec Section 2.9).

Recruitment of the 1998 year class $=3872$ million, which corresponds to the geometric mean (1972-1995) of the recruitment to the Western mackerel, raised by the average ratio (1.09) of the estimated Western and Southern area recruitments for the period 1984-1994 (the same as used for last year's prediction). Recruitment of the 1996 and 1997 year classes are assumed to be average.

Catch forecasts have been calculated for the provision of area based TACs. Two "fleets" have been defined, corresponding to the exploitation of the western area, including the North Sea and the unregulated catches taken in international waters, Division IIa (Northern), and the southern area (Southern).

The exploitation pattern used in the prediction was the separable ICA Fs for the final year taken from last year's assessment for the reasons given in Section 2.9. These were subdivided into partial Fs for each fleet using the average ratio of the fleet catch at each age and the total catch at each age for the years 1995-1997. Weight at age in the catch was taken as an average of the values for the period 1995-1997 for each area. Weight at age in the stock was calculated from an average (1995-1997) of weights at age for the NEA mackerel stock.

The total of agreed 1998 TACs over all by TAC regulated areas, increased by $80,000 \mathrm{t}$ compared to 1997 (see Section 2.1). The catch for 1998 is assumed to be $650,000 \mathrm{t}$ corresponding to the 1997 catch of $570,000 \mathrm{t}$ plus this TAC increase of $80,000 \mathrm{t}$.

Eight single option summary tables are presented and summarised in the text tables below. Tables 2.10.2.a-d refer status quo fishing mortality in 1998 and Tables 2.10.3.a-d to a constant catch option for 1998 of 650kt. Each of these two options for 1998 are then followed by:

F1999 = F2000 $=0.15$ as agreed between the EU and Norway for 1999;
F1999 $=\mathrm{F} 2000=0.175$ corresponding to F 0.1 ;
F1999 $=$ F2000 $=0.20$ corresponding to the mean F in the 80's when SSB remained stable;
$\mathrm{F} 1999=\mathrm{F} 2000=0.2325$ corresponding to the mean fishing mortality for the period 1995-1997.
UNITS: ‘000 t

|  | $\begin{gathered} \text { Catch } 1998=650 \mathrm{kt} \\ \mathrm{~F}=0.151999,2000 \\ \hline \end{gathered}$ |  |  | $\begin{aligned} & \hline \text { Catch } 1998=650 \mathrm{kt} \\ & \mathrm{~F}=0.1751999,2000 \end{aligned}$ |  |  | $\begin{gathered} \text { Catch } 1998=650 \mathrm{kt} \\ \mathrm{~F}=0.201999,2000 \end{gathered}$ |  |  | $\begin{gathered} \text { Catch } 1998=650 \mathrm{kt} \\ \text { F95-97=0.233 } \\ \hline 999,2000 \end{gathered}$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Year | Ref F | Catch | SSB | Ref F | Catch | SSB | Ref F | Catch | SSB | Ref F | Catch | SSB |
| 1998 | 0.23 | 650 | 2649 | 0.23 | 650 | 2649 | 0.23 | 650 | 2649 | 0.23 | 650 | 2649 |
| 1999 | 0.15 | 433 | 2771 | 0.175 | 500 | 2687 | 0.20 | 565 | 2663 | 0.233 | 648 | 2633 |
| 2000 | 0.15 | 458 | 2846 | 0.175 | 519 | 2768 | 0.20 | 575 | 2693 | 0.233 | 643 | 2599 |

Status quo F was only taken as the fishing mortality of 1997 and not as the a mean over the period 1995-1997, because the fishing mortality decreased considerably due to a strong decrease in the agreed TACs during this period. However, the option of a catch of 650 kt in 1998 and a $\mathrm{F}_{95-97}$ of 0.2325 in the following two years is approximately equal to a status quo F of 0.23 over the whole period of 1998 to 2000.

The forecasts predict that SSB will increase except when fishing mortality remains as high as the mean fishing mortality over the period 1995-1997 ( $\mathrm{F}=0.233$ ).

Two management option tables are presented. Table 2.10 .4 presents the option for status quo F in 1998, Table 2.10.5 presents a constant catch for each fleet in 1998; each is followed by a range of F98 values for both areas.

The forecasts for the two scenarios are in close agreement with the predicted SSB values, because no new assessment was carried out.

### 2.11 Short-Term Risk Analysis

ICES (1991/Assess:22) performed a sensitivity analysis for status quo forecasts made using data from this stock. The results revealed that the forecasts were sensitive to the estimates of the strength of the year class that recruited two years before the year of the assessment. The forecast made this year will be sensitive to the estimated fishing mortality in 1999.

Due to the decision of the Working Group to project the present stock numbers from 1997 to 1998 using the catch in 1997 (Section 2.9.1), last year's assessment was used as basis in the present short-term risk analysis. The sensitivity analysis need stock numbers, recruit estimates, F-values and other population parameters and their associated error estimates (CVs) to be run. Thus, the errors of the various population parameters of the 1997 ICA run were entercd into the sensitivity analysis together with population numbers for 1998 from the projection of last years assessment (Section 2.10). In the forecast the geometric mean of the time series (1972-1995) was used. To obtain an estimate of the CV for the recruitment the CV of the GM estimate was used. See Table 2.11.1 for a complete list of input data to the sensitivity analysis.

The WGFRAN4 and SENPLOT software produces a plot of the various (input) population parameters in descending order of significance to the uncertainty of the short-term prediction. The estimation of the accuracy of the catches or the fishing mortality in 1999 (HF99 - effort multiplier, see Table 2.11.1) is the single most important factor to the sensitivity of the short-term prediction (Figure 2.11.1).

The short-term risk ogive plots that were produced from the sensitivity analysis were not reproduced in the report due to the following concerns: 1) the present population input data to the sensitivity analysis were projected an extra year of reasons mentioned above, 2) the estimates of the stochastic crror terms representing the CVs of the population parameters were taken from last year's assessment, and 3) it was unclear to which extent the stochastic terms in this model covers the uncertainties in the present assessment (cf. Section 2.9.1).

### 2.12 Medium-Term Predictions

No new medium-term predictions were carried out because 1) last year's assessment was projected one year forward and 2) the actual catch taken in 1997 ( 570 kt ) was very similar to the assumed catch of 1997 ( 560 kt ) as used for the predictions at last ycar's Working Group mecting.

### 2.13 Long-Term Yield

Table 2.13.1 and Figure 2.13 .1 present the yield per recruit forecasts for the both arcas from 1997 Working Group report as no new assessment was done this year by the Working Group.
$F_{\text {max }}$ is poorly defined at a combined reference $F$ of about 0.5 . However, for pelagic species $F_{\text {max }}$ is generally estimated to be at levels of $F$ well beyond sustainable levels and should not be used as a fishing mortality target. $F_{0.1}$ was estimated last year using the same selection pattern, the full age range and a 12 plus group, to be 0.175 .

### 2.14 Reference Points for Management Purposes

The Working Group was asked to:
consider the reference points proposed by $S G P A F M$, adopting those reference points or presenting alternatives with reasons for the alternative selection.

In last year's Working Group Report (ICES 1998/Assess:6) an extensive and detailed analysis on potential candidates for reference points for the precautionary approach were given. The reference points suggested by SGPAFM were largely based on this analysis and are in line with the suggestions from the Working Group. The present Working Group found no reason for alternative reference points and decided to adopt the reference points suggested by SGPAFM shown in the text table below.

A new set of software for calculating reference points (PA Software Users Guide, CEFAS, Lowestoft) were presented to the present Working Group, which calculates the various precautionary reference points of spawning stock biomass and fishing mortality. The Working Group used the PA software to produce graphs and tables of the proposed reference points (Figures 2.14:1-6 and Tables 2.14.1-2). The values of the reference points calculated are similar to the values used previously by Working Group. In particular $F_{\text {loss }}(0.26)$ corresponds closely to the value of $F_{\text {lim }}=0.25$ used by the SGPAFM.

The MBAL value of 2.3 million t , which corresponds to $\mathrm{B}_{\text {loss }}$, has previously been regarded as a limit, below which strong measures were taken to bring the stock above this value. This is suggested as a $\mathrm{B}_{\text {na }}$. $A \mathrm{~B}_{\mathrm{lim}}$ cannot be defined in this case. A fishing mortality at $\mathrm{F}_{0.1}=0.175$ has been suggested last year by the Working Group (ICES 1998/Assess:6) as a target, and can be taken as $\mathrm{F}_{\mathrm{pa}}$. The fishing mortality at which the risk of stock depletion starts to increase in longterm simulations is suggested as a candidate $\mathrm{F}_{\mathrm{lim}}=0.25-0.3$ depending on the assumptions in the uncertainties in the models. This is based on an S-R relationship where R declines linearly to the origin below $\mathrm{B}_{\text {loss }}$. Consequently the Working Group proposes no change to the reference points previously proposed.

### 2.15 Harvest Control Rules

The subjects of reference points and management measures were treated extensively by the two last years' Working Groups (ICES CM 1997/Assess:3, ICES CM 1998/Assess:6). Since there is little new background information this year, no new evaluations of this kind have been made.

The Working Group has over several years recommended to maintain SSB above 2.3 million tonnes. This value corresponds approximately to the historical minimum, and was adopted as an MBAL value for the biomass. Within the range of historical SSBs, there is no clear dependence of the recruitment on the SSB. Below this value, there is no basis for assumptions about the stock-recruitment relationship.

The previous studies concentrated on a harvesting regime based on a constant fishing mortality, which should be set sufficiently low to imply a low risk of reducing the stock below the historical minimum. The recruitment of this stock has moderate year-to-year variations, and a fairly large number of year classes are represented in the fishery. In this case, a fixed catch regime might be considered. This could give a gain in terms of more stable and predictable catches, but would require a lower fixed catch than the average expected by an optimal fixed $F$ regime. It may also involve a greater risk of deteriorating the stock if the monitoring and management system is unable to react rapidly to unexpected changes in the state of the stock. A further alternative would be to set quotas for $2-3$ years, which is more relevant with this stock than with many others since the catch-independent information only comes every third year. If such alternatives are to be considered, they should be properly explored by simulations, which has not been done up till now.

### 2.16 Management Measures and Considerations

The exploitation history of this stock in relation to the proposed precautionary reference points is shown in Figure 2.16.1. For the time being, the suggestion by the Working Group would be a fixed F regime with an F-value close to $\mathrm{F}_{0.1}=0.175$ as also suggested by the Working Group in 1997 (ICES CM 1998/Assess:6), and shown in Figures 2.14.16. For 1998, ACFM recommended a fishing mortality in the range $0.15-0.20$, while the actual $F$ in 1997 was 0.22 . The

Working Group once again has to emphasise that the fishing mortalities derived from studies of predictions and simulation apply to the total exploitation of the stock, including areas where no quota regulations apply. At present, the stock is assumed to be slightly above 2.3 million tonnes. If the fishing mortality can be kept at the suggested level, the stock is expected to increase to a satisfactory level without further measures. A fishing mortality at the 1996-1997 level will, according to the medium-term predictions done by the 1997 Working Group, maintain the SSB at present levels.

Some discrepancies exist between areas used for catches and TAC areas, e.g. in the Southern area and in international waters. As for the other stocks, the Working Group recommends that the areas used for catch forecasting and TAC should be brought into correspondence.

Table 2.9.1.7c

## North Fast Atlantic mackerel. Diagnostic output.

IFAP run code: IOB
No of years for separable analysis : 12
Age range in the analysis : 0... 12
Year range in the analysis : 1984 . . . 1997
Number of indices of SSB : 1
Number of age-structured indices : 0

Parameters to estimate : 55
Number of observations : 149

Two selection vectors to be fitted.
Selection assumed constant up to and including : 1988
Abrupt change in selection specified.

Table 2.14.1 Western Mackerel: PA excel software add-in outputs (Input ICA_Mac.SEN file, Table 2.11.1).
Excel sheets of results included in the workbook W:ACFMIWGMHSA9984MAC_NEATPA_Mac.XLS:

RefPts - provides stochastic output in the form of a table of reference points and a chart summarising the distributions of some reference points.

Plots - provides 5 plots:
A stock recruitment plot with a LOWESS smoother as a possible stock recruitment relationship. Some reference points are also indicated.
A plot of YPR and SPR curves with some reference points indicated.
A plot of historical SSB against Fbar with an equilibrium curve based on the LOWESS stock recruitment relationship.
A plot of historical yield against Fbar with an equilibrium curve based on the LOWESS stock recruitment relationship.
A plot of the time series of stock and recruitment with expected recruits based on the LOWESS stock recruitment relationship.

PD - gives the value of the reference points during each iteration of the simulation and the percentiles plotted on the chart on RefPts.

SV - contains the steady state vectors and stock recruitment series used. These can be used as the basis for further runs.

For estimation of Gloss and Floss:
A LOWESS smoother with a span of 0.5 was used.
Stock recruit data were log-transformed
A point representing the origin was included in the stock recruit data.
For estimation of the stock recruitment relationship used in equilibrium calculations:
A LOWESS smoother with a span of 1 was used.
Stock recruit data were un-transformed
No point representing the origin was included in the stock recruit data.
Western Mackerel
Steady state selection averaged over 0 years.
Fbar averaged from age 4 to 8
Number of iterations $=100$

Table 2.14.2 Reference points calculated for Western mackerel (standard output from PA software). Equivalent SSB reference points and recruitment estimates for the Northeast Atlantic mackerel can be obtained by applying a scaling factor of 1.09 (ratio between NEA and western mackerel, see sec. 2.9.1). The MBAL for NEA mackerel is 2,3 million tonnes.

### 3.1 North Sea Mackerel

### 3.1.1 Biological data

The Western and Southern mackerel are mixing with the North Sea mackerel during the main fishing season. It is impossible to split the catches by the different components in the area where North Sea mackerel is distributed, Sub-area IV and Divisions IIa and IIIa. Catches of North Sea mackerel are included in the data for both North East Atlantic mackerel (Section 2) and western mackerel (Section 3.2). Since the SSB in the North Sea is only about $4 \%$ of that of North-East Atlantic mackerel, the catch of North Sea mackerel is assumed to be low. For multispecies assessment purposes this catch has for several years been assumed to be $10,000 \mathrm{t}$ (see Sections 12.1.1-12.1.3).

### 3.1.2 Fishery independent information

### 3.1.2.1 Egg surveys

An egg survey of the North Sea was carried out in 1996, the first since 1990. Temporal and spatial coverage was poor compared with that of 1990 , because only three surveys of the spawning area were carried out in 1996. The limited coverage resulted in some production areas being missed on the first survey. The SSB was estimated at $84,000 \mathrm{t}$. Using a mean atresia correction of $11.6 \%$, from the western area, increases the estimate of SSB to 110,000 t (ICES 1997/H:4).

New egg surveys are planned for 1999, tentatively 24 May-28 June, by the Netherlands and Norway.

### 3.1.2.2 Trawl surveys

For the first time in several years relatively large quantities of juvenile mackerel were observed in the North Sea and Skagerrak during the autumn 1996 ( 0 -group) and in 1997 (1-group). The abundance index of the 1996 year class as calculated from the North Sea International Young Fish Survey, first quarter of 1997, was very high (ICES 1998/Assess:6). This year class was not observed in the North Sea during the IBTS survey in the first quarter of 1998, but one year old mackerel (1997 year class) was observed during this survey (Figure 2.7.2.4), but not in the same quantities as the 1996 year class in the 1997 survey.

### 3.1.3 State of the stock

The estimated SSB from the egg surveys in 1996 was $110,000 \mathrm{t}$. Based on the egg surveys in 1990 the SSB was estimated at $78,000 \mathrm{t}$. This estimate was not adjusted for atresia and it is similar to the unadjusted estimate in 1996 of $84,000 \mathrm{t}$. The Working Group therefore still considers the North Sca mackerel to be severely depleted.

### 3.1.4 Management measures and considerations

The North Sea mackerel still needs maximum protection until the spawning stock shows evidence of recovery, while at the same time allowing fishing on the western and southern mackerel.

ACFM has for several years recommended the closure of Division IVa for fishing during the first half of the year until the Western Mackerel stock enters the North Sea in July-carly August. This fish stays there until late December or January the following year before migrating back to the spawning areas. The implemented restrictions for fishing in the North Sca have particularly during the first quarter resulted in large-scale misreporting from the Northern part of the North Sea (Division IVa) to Division VIa. To allow a fishery during the first quarter might solve the misreporting problem. This would have implications for North Sea mackerel which traditionally have overwintered partly in this area. However, the percentage of North Sea mackerel in this area during this quarter is uncertain.

The Working Group endorses the recommendations made by ACFM for several years:

- There should be no fishing for mackerel in Divisions IIIa and IVb,c at any time of the year;
- There should be no fishing for mackerel in Division IVa during the period 1 January- 31 July;
- The 30 cm minimum landing size at present in force in Sub-area IV should be maintained.

The closure of the mackerel fishery in Divisions IVb,c and IIIa the whole year will protect the North Sea stock in this area and the juvenile Western fish which are numerous particularly in Division IVb,c during the second half of the year. This closure has unfortunately resulted in increased discards of mackerel in the non-directed fisheries in this area as vessels at present are permitted to take only $10 \%$ of their catch as by-catch mackerel. No data on the actual size of mackerel by-catch have been available for the Working Group concerning 1997 but the reported landings of mackerel in Divisions IIIa and IVb,c for 1997 might be seriously under-estimated due to discarded by-catch.

### 3.2 Western Mackerel

### 3.2.1.1 Catch numbers at age

The 1997 catches in numbers at age by quarter for Western mackerel (Areas II, III, IV, V, VI, VII and Divisions VIIIa and VIIIb) are shown in Table 3.2.1.1.

The age structure of the catches of Western mackerel is predominantly 1-6 year old fish. The 1993 year class (4 year old fish) dominated the catches. Fish belonging to the 1996 year class were dominant in the catches in Q3 Division Vla. In other areas the catches were dominated by young fish; in IVb, IVc and VIIh catches were dominated by 1 year old fish; in VIId, and VIIe,f catches were dominated by 2 year olds; and VIIg catches were dominated by and 2 and 3 year old fish.

Age distributions of catches were provided by Denmark, England, Ireland, Netherlands, Norway, Russia, Scotland and Spain. There are still major gaps in the overall sampling for age from countries which take substantial catches, notably Faroes, France, Germany and Sweden (combined catch of $52,156 \mathrm{t}$ ). In addition there were no aged samples to cover the entire catch from VIIa, VIIg, VIIk and Va (total catch 528 t). As in 1997, catches for which there were no sampling data were converted into numbers at age using data from the most appropriate fleets. This is obviously undesirable where the only aged samples available are from a different type of gear.

Sampling data are further discussed in Section 1.4.1.

### 3.2.1.2 Mean lengths at age and mean weights at age

## Mean lengths

The mean lengths at age per quarter for 1997 for Western mackerel are shown in Table 3.2.1.2. These data continue the long time series and are useful in investigating changes in relation to stock size (D. Skagen, WD).

## Mean weights

The mean weights at age in the catches per quarter for 1997 for Western mackerel are shown in Table 3.2.1.3. The mean weights at age in the stock at spawning time for Western mackerel are given in Table 2.4.3.3. These data are based on samples from Dutch freezer trawlers (VIIb) and the Irish flect (VIlb, VIIj), fishing on the spawning grounds during the period March to May 1997.

### 3.2.1.3 Maturity ogive

The assumptions about maturity made by the Working Group in previous years were retained, including the reduced maturity at age 2 of the 1984 year class agreed in 1997 (ICES 1998/Assess:6). Maturity at age is now assumed constant for each year of the assessment. The values are given in the text table below:

| Age | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | $8+$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\%$ | 0 | 8 | 60 | 90 | 97 | 99 | 99 | 100 | 100 |

An estimation of the maturity ogive in 1998 will be obtained as part of the egg survey of the western area. In this context samples were taken over areas of predominantly juvenile distribution as well as on the spawning grounds The total number of samples taken is not yet available, but it seems likely that it will fall short of the ten targeted by the Planning Group (see Section 1.5.2). The samples will be analysed by histological examination to provide a more reliable estimate of the numbers of fish which will actually spawn in that year.

### 3.2.2 Fishery independent information

### 3.2.2.1 Egg surveys

Information on the historic time series of egg surveys which cover the area of the Western stock are given in Section 2.5.2. The scaling used to relate NE Atlantic egg survey estimates to the Western arca is 0.85 .

### 3.2.2.2 Trawl surveys

Bottom trawl surveys which provide information on Western stock juvenile mackerel include: Scottish surveys to the north and west of the British Isles in quarters 1 and 3, an English survey in the western approaches in quarter 1 and an Irish survey on the west coast of Ireland in quarter 4. Distribution of relevant data is given in Section 2.7.2. The index of recruitment derived from these surveys was not used in the assessment; reasons for this are given in Section 2.5.4. A Generalised Additive Model (GAM) was used to try and improve the performance of the recruitment index; details of this are given in Section 2.7.2. Data from these surveys continue to be the only source of information on the distribution of juvenile mackerel.

### 3.2.3 State of the stock

An assessment on Western mackerel was not carried out this year due to the reasons given in Section 2.9.1. Some data exploration with and without the preliminary 1998 egg survey estimate of biomass is presented in Section 2.9.1.

### 3.3 Southern Mackerel

### 3.3.1 Biological data

The catch in numbers, mean lengths and mean weights at age for Divisions VIII c and IX a are discussed in Section 2.4 (Tables 2.4.1, 2.4.2 and 2.4.3-NEA mackerel).

Tables 3.3.1.1 and 3.3.1.2 show the total catch in numbers and mean weights at age for Southern mackerel (Divisions VIIIc and IXa) for 1984-1997.

## Mean weights at age in the stock

The mean weights at age in the stock for the southern mackerel are based on samples obtained from the commercial catches during Quarter 1 and Quarter 4 as a mean over 1991 to 1995 (table below):

| Stock Weights at Age (kg) for Southern Mackerel |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Age in Years |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15+ |
| . 161 | . 248 | . 305 | . 354 | . 385 | . 427 | . 455 | . 493 | . 511 | . 545 | . 548 | . 617 | . 622 | 656 | . 716 |

## Maturity ogive

The assumption made about Southern mackerel maturity ogive is the same as in previous years (ICES 1997/Assess;3) (sec text table below):

| Maturity ogive of mackerel from southern area |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Age |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15+ |
| . 45 | . 89 | . 95 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

### 3.3.2 Fishery independent information and CPUE indices of stock size

### 3.3.2.1 Egg surveys

Data from mackerel egg surveys carried out in the Spanish and Portuguese waters during 1998 are at present not available. They will be presented to the Mackerel/Horse Mackerel Egg Survey Working Group.

### 3.3.2.2 Demersal trawl surveys

Table 3.3.2.2.1 shows the numbers at age per half hour trawl from the Spanish bottom trawl surveys from 1984 to 1997 in September-October and the numbers at age per hour trawl (*1000) from Portuguese bottom trawl autumn surveys from 1986 to 1997.

The two sets of autumn surveys covered Sub-divisions VIIIc East, VIIIc West and IXa North (Spain) from 20-500 m depth and Sub-divisions IXa Central North, Central South and South (Portugal), from $20-750 \mathrm{~m}$ depth. The same sampling methodology is used in both surveys but there are differences in the gear design.

### 3.3.3 Effort and catch per unit effort

This information is now given in Section 2.6.1.

Table 3.2.1.1 Catch numbers at age (000's) by quarter for Western mackerel in 1997.

### 4.1 Fisheries in 1997

The total international catches of horse mackerel in the North East Atlantic are shown in Table 4.1.1 and Figure 4.3.1. The total catch from all areas in 1997 was $519,000 \mathrm{t}$ which is $60,000 \mathrm{t}$ more than in 1996 and the second highest on record. Ireland, Denmark and the Netherlands have a directed trawl fishery and Norway a directed purse seine fishery for horse mackerel. Spain and Portugal have a directed trawl and purse seine fishery.

The quarterly catches of horse mackerel by Division and Sub-division in 1997 are given in Table 4.1.2. The distribution of the fisheries in 1997 are given in Figure 4.1.1.a-d. The figures are based on data provided by Denmark, England and Wales, Germany, Ireland, the Netherlands, Norway, Portugal and Spain covering $80 \%$ of the total catches.

First quarter: $176,500 \mathrm{t}$. This is $13,000 \mathrm{t}$ more than 1996. The catches this quarter (Figure 4.1.1.a) are distributed in the western and southern areas as in previous years, while hardly any catches were taken in the Scotland-Shetland area this year.

Second quarter: $76,000 \mathrm{t}$. This is $18,000 \mathrm{t}$ more than in. 1996. As usual, rather low catches were taken during the second quarter and the catches are distributed as in previous years (Figure 4.1.1.b).

Third quarter: $86,000 \mathrm{t}$. This is the same catch level as in 1996, and the catches were distributed as in previous years (Figure 4.1.1.c).

Fourth quarter: $180,500 \mathrm{t}$. This is the quarter when relatively large catches have been taken in Division IVa since 1987. The catches in this quarter were reduced from $260,000 \mathrm{t}$ in 1995 to $153,000 \mathrm{t}$ in 1996. This was particularly due to a drop in the fishery in Division IVa. In 1997 the fishery increased in this Division by about $30,000 \mathrm{t}$ (see Section 6.13). The catches were distributed as in previous years (Figure 4.1.1.d).

### 4.2 Stock Units

The last 9 years the Working Group has considered the horse mackerel in the north east Atlantic as separated into three management stocks: the North Sea, The Southern and the Western stocks (ICES 1990/Assess:24, ICES 1991/Assess:22). Since little information from research surveys is available, this separation is based on the observed egg distributions and the temporal and spatial distribution of the fishery. Western horse mackerel are thought to have similar migration patterns as Western mackerel. As for mackerel, the egg surveys have demonstrated that it is difficult to determine a realistic border between a western and southern spawning area. In later years some horse mackerel have been tagged in Portuguese and Spanish waters, but so far no tags have been recovered.

### 4.3 Allocation of Catches to Stocks

There is no information available about when and where the catches reported from Division IIIa were taken. Usually most of these catches have been taken in the western part of the Division in third and fourth quarter which is closer to the catch distributions in Division IVa than in Divisions IVb,c both spatially and temporally.

In 1997, $2,617 \mathrm{t}$ were reported as landed from Division IIIa and these catches were assumed taken from the western part of the Division during the third and fouth quarter and thereby allocated to the western stock. During the fourth quarter the Norwegian fishery extended from Division IVa into the northern part of Division IVb where $1,426 \mathrm{t}$ were taken. These catches were also allocated to the western stock. Except for these catches, the catches in 1997 were as in previous years allocated to the different stocks as:

Western stock: Divisions IIa, IIIa (western part), Vb, IVa, VIa, VIIa-c,e-k and VIIIa,b,d,e.
North Sea stock: Divisions IIIa (eastern part), IVb,c and VIId.
Southern stock: Divisions VIIIc and IXa
The catches by stock are given in Table 4.3.1 and Figure 4.3.1. Only one country provides data for discards. Therefore the amount of discards given in Table 4.3.1 are not representative for the total fishery.

At present there is only set a TAC for the western stock. However, this TAC only applies to EU waters. The present management area for this stock is therefore Divisions VIa, VIIa-c,e-k and VIIIa,b,d,e and western part of Division IVa,
which do not cover the total distribution area. If TACs are set by stocks, they should apply to all areas where the different stocks are distributed:

Western stock: Divisions IIa, IIIa (western part), Vb, IVa, VIa, VIIa-c,e-k and VIIIa,b,d,e.
North Sea stock: Divisions IIIa (eastern part), IVb,c and VIId.
Southern stock: Divisions VIIIc and IXa.

### 4.4 Estimates of Discards

At present only one country - the Netherlands - is providing information on discards but this information is not applied to any other fleets.

Information on discarding by the Dutch fleet is obtained from part ( $15-20 \%$ ) of the pelagic fleet which is regarded to be representative for all areas and months where the pelagic fleet is operating (see also Section 1.7 on fleet description). Estimates on discards are not made by independent observers of the fishery activities, but the crew collects information during each trip per haul concerning date, position, trawl duration, catch composition by species. This estimation of the catch of each haul is done at the time the catch is taken on board (before any discarding takes place). If a catch is lost by torn nets, it is also reported. The information on species composition of the catch is added later. Finally the information on discards is obtained by comparing catch and actual reported landings. This discard information by species is then applied to only the whole Dutch pelagic fleet by month and by ICES Division, but not to the international fleet. This report contains a number of tables in which catches and discards are reported on an annual basis, but not on a quarterly basis (however, the basic discard data are available by month and by ICES Division). General information on discards in the pelagic fleets is provided in Section 1.4.3.

### 4.5 Species Mixing

## Trachurus sp.

Three species of Trachurus genus, T. trachurus, T. mediterraneus and T. picturatus are found together in the north east Atlantic waters and are commercially exploited in parts of the Sub-area VIII and Division IXa. Studies on genetic differentiation showed three clear groups corresponding to cach species of Trachurus with no intermediate principal component scores, excluding the possibility of hybrids between species (Soriano, M. and Sanjuan, WD 1997).

Following the Working Group recommendation (ICES 1998/Assess:6), special care was again taken to ensure that catch and length distributions and numbers at age of $T$. trachurus supplied to the Working Group did not include $T$. mediterraneus and $T$. picturatus. Spain provided data on T. mediterraneus and Portugal on T. picturatus.

Table 4.5.1 shows the catch of T. mediterraneus by Sub-divisions since 1989. In Divisions VIIIa,b and Sub-division VIIIc East, the total catch of $T$. mediterraneus was $3,822 \mathrm{t}$ in 1997. In Sub-division VIIIc West and Division IXa North there are no catches of this species.

As in previous years in both areas, more than $95 \%$ of the catches were obtained by purse seincrs and the main catches were taken in the second half of the year, mainly in autumn, when the $T$. trachurus catches were lowest. $T$. mediterraneus catches were lowest in spring.

Catches and length distributions of $T$. mediterraneus in the Spanish fishery in Divisions VIIIa,b and c were reported separately from the catches and length distributions of T. trachurus. Data of monthly landings by gear and area were obtained from fishing vessel owner's associations and fishermen's associations through the existing information network of the IEO and AZTI (Advisory Organisations to Fisheries and Oceanography Administration) in all ports of the Cantabrian and Galician ports. T. mediterraneus is only landed in ports of the Basque country, Cantabria and Asturias. In ports of the Basque country the catches of T. mediterraneus and T. trachurus appear separately, except some small categories, in which the separation is made on the basis of samplings carried out in ports and information reported by fishermen. In the ports of Cantabria and Asturias the separation of the catch of the two species is not registered in all the ports, for which reason the total separation of the catch is made based on the monthly percentages of the ports in which these catches are separated and based on samplings made in the ports of this area.

A fishery for T. picturatus only occurred in the southern part of Division IXa, as in previous years. Data on T. picturatus in the Portuguese fishery for the period 1986-1997 are also given in Table 4. 5.1. Catches and length distributions of $T$. trachurus for the Portuguese fishery in Division IXa do not include data for $T$. picturatus. Landings data are collected
from the auction market system and sent to the General Directorate for Fisheries to be compiled. This includes information on landings per species by day and vessel.

As information is available on the amounts and distribution of catches of T. mediterraneus and T. picturatus for at least nine years (ICES 1990/Assess:24, ICES 1991/Assess:22, ICES 1992/Assess:17, ICES 1993/Assess:19, ICES 1995/Assess:2, ICES 1996/Assess:7, ICES 1997/Assess:3, and ICES 1998/Assess:6), and as the evaluations and assessments are only made for T. trachurus, the Working Group recommends that the TACs and any other management regulations which might be established in the future should be related only to T. trachurus and not to T. trachurus spp. in general, as is the case at present. It would then be appropriate to set TACs for the other species as well.

### 4.6 Length Distribution by Fleet and by Country

The 1997 annual length composition by fleet were provided by the Denmark, Netherlands, Norway, Portugal and Spain. These length distributions cover $75 \%$ of the total landings and are shown in Table 4.6.1.

Table 4.1.1 Landings (t) of HORSE MACKEREL by Sub-area. Data as submitted by Working Group members.

Figure 4.3.1
Total catches of horse mackerel in the northeast Atlantic during the period 1965-1997. The catches taken by the USSR and catches taken from the southern, western and North Sca horse mackerel stocks are shown in relation to the total catches in the northeast Atlantic.

## NORTH SEA HORSE MACKEREL (DIVISIONS IIIa - EXCEPT WESTERN PART OF SKAGERRAK IVb,c AND VIId)

### 5.1 ACFM Advice Applicable to 1997 and 1998

As usual, no TAC advice was given. The agreed TAC has been fixed at $60,000 \mathrm{t}$ since 1993 and the catches have varied between $6,500 \mathrm{t}$ and $19,500 \mathrm{t}$ in the same period. In May 1998 ICES recommended that consistent with a precautionary approach a management plan including monitoring of the development of the stock and fishery with corresponding intervention rules should be developed and implemented.

### 5.2 The Fishery

The total catch taken from the North Sea and Division IIIa dropped from a level of $100,000 \mathrm{t}-140,000 \mathrm{t}$ during the period 1992-1995 to 28,000 t in 1996 and increased to about $80,000 \mathrm{t}$ in 1997.

Usually catches taken in Divisions IIIa - except western part of Skagerrak - IVb,c and VIId are regarded as belonging to the North Sea horse mackerel stock (see Sections 4.2 and 4.3). Table 4.3.1 shows the catches of this stock from 19821997. The total catch taken from this stock in 1997 was $19,500 \mathrm{t}$ which is the same level as the previous two years. In previous years most of the catches from the North Sea stock were taken as a by-catch in the small mesh industrial fisheries in the fourth quarter carried out mainly in Divisions IVb and VIId. However, since 1995 at least $70 \%$ of the catch has been taken in a directed horse mackerel fishery for human consumption.

### 5.3 Fishery Independent Information, Egg Surveys

Horse mackerel egg surveys in the North Sea were carried out from 1988 to 1991 and the spawning stock biomass estimated were respectively $120,217,255$ and 247 thousand tonnes (Eltink, 1992). The 1988 estimate was regarded as an underestimate. No egg surveys have been carried out since 1991.

### 5.4 Biological Data

### 5.4.1 Catch in numbers at age

Catch in numbers at age data were calculated according to Dutch data (Tables 5.4.1.1 and 5.4.1.2). In 1997 the Dutch catches comprised $57 \%$ of the total. For the earlier years age compositions were presented based on samples taken from smaller Dutch commercial catches and research vessel catches. These are available for the period 1987-1995. In the earlier years the Dutch samples covered only a small proportion of the total catch, but give a rough indication of the age composition of the stock (Figure 5.4.1.1).

The strength of the 1982 year class in the central and southern North Sea does not seem as strong as in the western area (Figures 5.4.1.1 and 6.4.1.1). The 1987 year class is relatively stronger in the western stock than in the North Sea. In the 1997 catches the 1994 year classes are relatively abundant both in the western catches and in the North Sea catches.

### 5.4.2 Mean length at age and mean weight at age

Mean length at age and mean weight at age in the catches based on the Dutch data are given in Tables 5.4.1.1 and 5.4.1.2.

### 5.4.3 Maturity at age

No data have been made available for this Working Group.

### 5.4.4 Natural mortality

There is no information available about natural mortality.

### 5.5 State of the stock

It was not possible to do an analytical assessment. Estimates of total age compositions are available only for the years 95,96 and 97 based on mainly Dutch samples. Estimates of age compositions before 1995 are considered unreliable, that is, not representative for the entire fishery, and should not be used for analytical assessment.

The egg surveys carried out in 1989, 1990 and 1991 resulted in an average spawning stock biomass of 240,000 t over this period (Eltink, 1992). As the estimated stock biomass is large compared to the annual landings $(4,000 t-33,000 \mathrm{t}$ with an average of $18,000 \mathrm{t}$ during the period 1982-1997), the stock may be lightly exploited.

If an assessment for this stock is required improved catch sampling and independent estimates of SSB are necessary.

### 5.6 Reference Points for Management Purpose

Reference points can not be defined for this stock, as estimates of recruitment and biomass are not available.

### 5.7 Harvest Control Rules

No harvest control rules were considered since no assessment was carried out.

### 5.8 Management Measures and Considerations

No forecast was made for 1999. The data were insufficient to define a management plan for this stock.
The Working Group recommends that if a TAC is set for this stock, it should apply to those areas where North Sea horse mackerel are fished, i.e. Divisions IVb,c, VIId, and eastern part of Division IIIa.
 NORTH SEA HORSE MACKEREL by quarter and by Division(s) in 1997.

Figure 5.4.1.1 The age composition of the NORTH SEA HORSE MACKEREL based on commercial and research vessel samples from 1987-1997. VIIe-k, AND VIIIa,b,d,e

### 6.1 ACFM Advice Applicable to 1997 and 1998

Both for 1997 and 1998 ICES recommended a substantial reduction of fishing mortality, at least to 0.15 corresponding to a catch of $173,000 \mathrm{t}$, and $150,000 \mathrm{t}$ in 1997 and 1998 respectively. This was aimed at maintaining the SSB above that which produced the 1982 year class. The TAC should apply to all areas where western horse mackerel are fished. The total landings of this stock in 1997 were $442,000 \mathrm{t}$ which was $269,000 \mathrm{t}$ more than recommended.

### 6.2 The Fishery in 1997

The fishery for the western horse mackerel is carried out in Divisions IIa, IIIa (western part) IVa, VIa, VIIa-c,e-k and VIIIa,b,d,e. The national catches taken by the countries fishing these areas are shown in Tables 6.2.1-6.2.5, while information on the development of the fisheries by quarter and division is shown in Table 4.1.2 and in Figures 4.1.1a-d.

## Divisions II a and Vb

The national catches in this area are shown in Table 6.2.1. The catches in this area have varied from year to year. The catches dropped from the record high catch of $14,000 \mathrm{t}$ in 1995 to about $3,400 \mathrm{t}$ in 1996 and $2,600 \mathrm{t}$ in 1997.

## Sub-area IV and Division IIIa (western part)

The total catches in this area have been above or close to $100,000 \mathrm{t}$ during the period 1989 to 1995 (Table 6.2.2). In 1996 the catches dropped by about $75 \%$, mainly because of considerable reduction in the Norwegian purse seine catches in Division IVa. Mainly due to increased Dutch and Norwegian catches in 1997 the total catch was $79,000 \mathrm{t}$.

## Sub-area VI

The catches in this area have increased from $21,000 \mathrm{t}$ in 1990 to a historical high level of $84,000 \mathrm{t}$ in 1995 and $81,000 \mathrm{t}$ in 1996 (Table 6.2.3). The catches in 1997 were reduced by $50 \%$ to $40,000 \mathrm{t}$. The main part of the catches is taken in a directed Irish trawl fishery for horse mackerel.

## Sub-area VII

The catches from this area are mainly taken in directed Dutch and Irish trawl fisheries in Divisions VIIb,e,h,j (Table 6.2.4). The catches increased to a historical high level in 1995 of $330,000 \mathrm{t}$. After a reduction in the catches in 1996 of about 50,000 t the catches in 1997 were back at the high 1995 level.

## Sub-area VIII

The catches from this area are mainly taken in Divisions VIIIa,b,d,e and given in Table 6.2.5. Historical high catches of more than $53,000 \mathrm{t}$ were taken in 1992 and 1993. In 1995 the catches declined to $21,000 \mathrm{t}$ and increased to $41,000 \mathrm{t}$ in 1997.

### 6.3 Fishery Independent Information from Egg Surveys

The historic time series of stage 1 egg production and SSB estimates, for the western area from 1977 to 1985, was updated at the Working Group in 1997 (Table 2.2.1 in ICES 1998/Assess:6). No further changes have been made to that data set.

At the planning meeting in Lisbon for the 1998 mackerel and horse mackerel egg surveys of the western and southern areas, the Working Group agreed that preliminary results of the 1998 egg surveys would not be available in time for either the current Assessment Working Group or for the October meeting of ACFM. Although some egg survey results might be available by the end of September, work on the analysis of the samples for fecundity, atresia and maturity at age will not be completed until carly in 1999. As a consequence only an incomplete set of egg survey results, are available from the 1998 egg survey (see Section 1.5.2) These data have not been subjected to a rigorous check and must therefore be regarded as only preliminary.

The following information, on egg distribution was available:

In the first sampling period in the western area, period 3, the major concentration of spawning was along the shelf edge from southern Biscay to the Great Sole Bank with some diffuse spawning to the north of that area over the Celtic Sea and to the west of Ireland. The boundaries of the distribution were fairly well defined in this period.

By the next sampling period spawning intensity had increased rapidly and was strongly associated with the shelf edge from southern Biscay to south-west of Ireland. The boundaries of the distribution were well defined except at the southern limit of the western area where concentrations of over 100 stage 1 eggs per $\mathrm{m}^{2}$ were found.

Spawning had declined by the next period, period 5, with sporadic concentrations along the shelf edge from northern Biscay to west of Ireland with virtually no spawning north of $53^{\circ} \mathrm{N}$. The results of sampling from central Biscay southwards were not available.

Spawning increased again in the final sampling period, period 6, to reach a seasonal peak, $50 \%$ above the production in period 4. Spawning was strongly concentrated in the area between $48^{\circ} \mathrm{N}$ and $54^{\circ} \mathrm{N}$. and spread eastwards, from the shelf edge, into the Celtic Sea. The boundaries of this distribution were very well defined. A small, isolated, production of stage 1 eggs was also located in central Biscay but analysis of the samples in this area is not complete.

The preliminary estimate of stage 1 horse mackerel egg production, from the samples analysed to date, is approximately $20 \%$ lower than the production measured in 1995.

### 6.4 Biological data

### 6.4.1 Catch in numbers

As in previous years only two countries provided sample data with age readings, the Netherlands (Divisions VIa, Subareas IV, VII and VIII) and Norway (Division IIa, IVa). This means that about $43 \%$ of the catches were sampled for age determinations. Catches from other countries were converted to numbers at age using the Dutch and Norwegian data.

The catch in numbers at age by quarters and Divisions for western horse mackerel is shown in Table 6.4.1.1. The total annual catch in numbers for 1997 is shown in Table 6.4.1.2. The sampling intensity is discussed in Section 1.3. The 1982 year class has until last year (Figure 6.4.1.1) been the most numerous in the catches from the western stock. This age group is now part of the plus group which is $8 \%$ of the total catch in numbers.

### 6.4.2 Mean length at age and mean weight at age

Mean length at age and mean length at age in the catches
Mean weights and mean lengths at age in the catches by quarters in 1997 were as usually provided only by Netherlands and Norway. These data were applied to the catches from other countries. The mean weight and mean length at age in the catches are shown in Tables 6.4.1.2, 6.4.2.1, and 6.4.2.2.

## Mean weight at age in the stock

As for previous years the mean weight at age for the two years old was given a constant weight while the weight for the older ages is based on all mature fish sampled from Dutch freezer trawlers the first and second quarter in Divisions VIIj,k (Table 6.4.1.2).

## Projected weights at age in catches and in the stock 1998-2007

Projected weights at age in the catches and weights at age in the stock are needed for the forecasts. The mean weights at age in the catch and in the stock for the period 1997-2007 were, except for the 1982 and the 1987, set as the mean weights from 1995, 1996 and 1997. The weight at age in catch and in the stock of the 1982 and the 1987 year classes were obtained from extrapolated growth curves over the period 1998-2007. The mean weights at age in the catch and in the stock of the 1982 year class have been used for the $15+$ group since the majority of this group consists of the 1982 year class. The projected weights at age in catches and in the stock for 1998-2007 are given in Table 6.8.1.1.

### 6.4.3 Maturity at age

Annual changes in the mean weights at age are expected to be related to annual changes in the maturity ogive. Therefore, the maturity ogive should be estimated for each year to take into account possible differences in growth rates. This was discussed in ICES (1998/Assess:6).

During the mackerel/horse mackerel egg surveys in 1998 horse mackerel were collected to estimate the proportion mature by histological analysis to improve the maturity ogive. However, these data are not analysed yet.

### 6.4.4 Natural mortality

The natural mortalities applied in the assessments of western horse mackerel are summarised and discussed in ICES (1998/Assess:6) and the Working Group admitted uncertainties in M in the range of 0.05 to 0.15 .

### 6.5 State of the Stock

A Bayesian approach has been used to calculate the Western horse mackerel stock assessment. This has been chosen as being an appropriate method of admitting perceived uncertainties in assumptions in the assessment, and of estimating uncertainties in the perceptions of stock size and subsequent short- and medium-term forecasts. An accessible introduction to Bayesian methodology in a fisheries context is given by Hilborn and Walters (1992). Estimates calculated by this approach can reflect uncertainty in assumptions as well as noise in the data around a given structural model. One difference between the Bayesian and conventional approach is that no attempt is made to find a 'best' set of parameter estimates or 'best' VPA. Instead, over a wide range of plausible prior assumptions, the data are compared with the assessment model using a likelihood function. For any particular parameter such as spawning stock size or a future catch under a particular catch option, the perceived ('posterior') probability of each stock size or catch option can be calculated. It is not necessarily the case that the likeliest estimates of all the parameters, or even their expected values, should be consistent through a single calculation of the assessment model. This can happen because of nonlinearities and parameter correlations in the assessment model. The Working Group does not therefore provide a single 'final' VPA, but instead provides expected values and distribution percentiles for quantities judged to be of management interest. The calculating mechanism is described briefly in Appendix 1 of ICES (1998/Assess:6), which is a summary of a description given in Patterson (1997).

As has been noted in two previous Assessment Working Group reports (ICES 1996/H:2, ICES 1997/Assess:3) the assessment of Western horse mackerel presents peculiar and special difficulties. The stock is dominated by two cohorts, the extremely strong 1982 and the much less abundant 1987 year classes comprising the bulk of the catches in recent years. Although there exist plausible catch-at-age data for the period 1982 to 1996 and there also exists a time-series of egg survey estimates of spawning biomass (ICES $1996 / \mathrm{H}: 2$ ) it is not a straightforward task to use the egg survey estimates to 'tune' a population model to the egg survey estimates. This is because maturation of horse mackerel appears to be density-dependent, and also because sampling for maturation is subject to unknown bias due to migration effects. Lastly, the assumption of natural mortality, $\mathrm{M}=0.15$ was made arbitrarily. Alternative choices of M were explored briefly by ICES (1997/Assess:3) which suggested that lower rather than higher values of $M$ may provide better fits of VPA-derived population models to egg survey biomass estimates.

The problematic nature of the assessment has led to rather poor consistency in advice. Estimates of the abundance of the 1982 year class have been revised upwards successively by successive working groups, and as new egg survey estimates were added to the time-serics, the perception of the precision of the earlier surveys was diminished.

Here an attempt is made to make a more comprehensive assessment of uncertainty in some quantities used for management purposes (spawning stock size, fishing mortality, $\mathrm{F}_{\text {status quo }}$ catch) that includes uncertainty in some critical quantities (maturity ogive, natural mortality). A Bayesian VPA-based method based on a Markov Chain Monte Carlo method similar to that used for Norwegian Spring-Spawning Herring (Patterson and Eltink, WD 1997) is used. In addition to the age-structured observation data set, this requires the specification of prior distributions for quantities about which limited or subjective knowledge is available.

### 6.5.1 Model

### 6.5.1.1 Structural model for assessment

As last year, the underlying structural population model is of the 'ADAPT' type, structured so as to make all historic and recent population abundances and mortalities dependent on two parameters, being the abundance of fish aged 14 on 1 January 1998 and the natural mortality. The model is similar to that described by ICES (1997/Assess:3), albeit with slightly different exploitation pattern assumptions. The following constraints were imposed:

- Selection (relative fishing mortality) in 1997 and later years is constrained $=1$ on ages 4 and older.
- Selection on ages 0 to 3 in 1997 is calculated by linear interpolation between 1 at age 4 and 0 at age 0 :
- Fishing mortality on the oldest age is taken as the arithmetic mean from age 6 to the penultimate true age in the catch at age matrix.
- Recruitments from 1994 to 1997 were modelled as a geometric mean of recruitments in the years 1981, 1983-1986 and 1988-1992 (see Section 6.8) in order to avoid inferring recent recruitments from a selection pattern assumption.

### 6.5.1.2 Probability model

The likelihood function is defined analogously to that for the conventional assessment, based on the lognormal distribution. With usual notation indexed by year y and age a, (Egg surveys $U_{y}$, Population abundance $N_{a}, y$, Maturity ogive $O$, fishing mortality $F$, natural mortality $M$, survey variance sigma and the proportions of fishing and natural mortality experienced before the time of the survey PF and PM):
$\mathrm{P}($ Data $\backslash$ Model $)=\Pi_{\mathrm{y}}\left(\frac{1}{\mathrm{U}_{\mathrm{y}} \sigma(2 \pi)^{1 / 2}} \exp \left(-\frac{\left[\log \left(\mathrm{U}_{\mathrm{y}} / \Sigma_{\mathrm{a}} \mathrm{N}_{\mathrm{a}, \mathrm{y}} \mathrm{O}_{\mathrm{a}, \mathrm{y}} \mathrm{W}_{\mathrm{a}, \mathrm{y}} \exp \left(-\mathrm{PF}, \mathrm{F}_{\mathrm{a}, \mathrm{y}}-\mathrm{PM}, \mathrm{M}_{\mathrm{a}, \mathrm{y}}\right)\right)\right]^{2}}{2 \sigma^{2}}-\right)\right)$

### 6.5.2 Data and priors

### 6.5.2.1 Data assumed known precisely

Estimates of landings and estimates of catches at age in numbers, weights at age in the catches and weights at age in the stock were as described in Sections 6.4.1 and 6.4.2 and given in Tables 6.5.2.1 to 6.5.2.3.

### 6.5.2.2 Uncertainty in maturity

The assumptions concerning the uncertainty in maturity were comprehensively discussed in last year's report (ICES 1998/Assess:6). The following assumptions for the prior distributions for maturity have been made, based on hypotheses about plausible maturities that are described in Section 6.5:

1. The strongest year class before the 1982 year class was the 1979 year class, which did not show a retarded growth until 1983. The percentage mature is assumed to be in the range of $75 \%$ to $100 \%$ with equal probability for all values.
2. Fish of the 1982 year class in 1983 at age 1 are assumed to be all immature, no uncertainty admitted.
3. Because of the retarded growth, the fish of the 1982 year class in 1986 and 1989 at respectively ages 4 and 7 are assumed to have a completely unknown maturity in the range of 0 to $100 \%$ with equal probability. It is assumed that the maturity in 1989 must be greater than in 1986.
4. Fish of the 1982 year class in 1992 at age 10 are assumed in the range of 80 to $100 \%$ mature with equal probability.
5. Fish of the year class 1992 in 1995 at age 3 are assumed to have a maturity in the range of 0 to $100 \%$, but less mature than the 1979 year class in 1983.
6. Fish of the 1982 year class in 1995 at age 13 are assumed to be all mature with no uncertainty admitted.

These maturity assumptions described above were parameterised as follows, and depending on five parameters $X_{1.5}$ :

$$
\begin{aligned}
& M O(1983,4)=\mathrm{X}_{1} \\
& M O(1986,4)=\mathrm{X}_{2} \\
& M O(1989,7)=\mathrm{X}_{3}\left(1-\mathrm{X}_{2}\right)+\mathrm{X}_{2} \\
& M O(1992,10)=\mathrm{X}_{4} \\
& M O(1995,3)=\mathrm{X}_{5} . \mathrm{X}_{1}
\end{aligned}
$$

The maturity at age for the remaining years and ages are given in Table 6.5.2.4.

### 6.5.2.3 Uncertainty in natural mortality

In the 1996 assessment of this stock trials with M in the region $+/-50 \%$ around $\mathrm{M}=0.15$ were made. Here we consider admissible hypotheses for $M$ in the range 0.05 to 0.15 , for reasons referred to in Section 6.4. No attempt was made to explore uncertainty about possible differences in natural mortality at age.

### 6.5.2.4 Egg survey data

The coefficient of variation of the 1992 western horse mackerel egg survey estimates was estimated at between 18 and $22 \%$ depending on the analytic method used (ICES 1994/H:4). For present purposes the egg survey abundances estimates were assumed to be estimated with a CV of $25 \%$ on a lognormal distribution. No uncertainty was admitted in this variance estimate.

This year a preliminary estimate of the spawning stock biomass was available from the 1998 surveys (Section 6.3). Due to the recent downwards trend in the ADAPT estimates of SSB, which have been projected to go below the MBAL of 500 kt in the short term, the Working Group considered that the preliminary estimate should be included within the assessment. Although it is considered that when the final egg survey estimate is available next year the value will be revised, it was treated as having the same CV as the previous surveys.

### 6.5.2.5 Summary of prior assumptions

The prior distributions are summarised in the text table below. All prior distributions are uniform.

| Parameter |  | Lower Bound | Upper Bound | Comment |
| :--- | :--- | :--- | :--- | :--- |
| $\mathrm{N}_{1998,14}$ | Population Abundance <br> (thousands) | Natural Mortality | 1000 | $8.10^{9}$ |
| M | Maturity 1983 age 4 | Unrestrictive, reference <br> parameter for VPA |  |  |
| $\mathrm{X}_{1}$ | Maturity 1986 age 4 | 0.75 | Section 6.4 |  |
| $\mathrm{X}_{2}$ | Maturity 1989 age 7, additional to <br> maturity 1986 age 4 | 0 | 1.0 | Section 6.5.2.2 |
| $\mathrm{X}_{3}$ | Maturity 1992 age 10 | 0 | 1.0 |  |
| $\mathrm{X}_{4}$ | Relative Maturity 1995 age 3 | 0 | 1.0 |  |
| $\mathrm{X}_{5}$ | 0.8 | 1.0 |  |  |

### 6.5.3 Stock assessment

Estimates of the historic development of the stock parameters are plotted in Figure 6.5.3.1, and the expectations and 5th, 25th, 50 th, 75 th and 95 th percentiles of these distributions are given in Table 6.5.3.1. From Figure 6.5.3.1. it can be seen that the 1983 and 1986 egg survey observations lie outside the 95 th percentile of the SSB distribution, indicating that even with the relaxation of assumptions allowed in this assessment compared with the conventional assessment procedure, the early egg surveys in the time series, the reported catches, the VPA assumptions and the assumption of a $25 \%$ CV in egg survey estimates are mutually incompatible. The preliminary estimate for the 1998 survey biomass lies within the 95 percentile of the stock trajectory.

It should be noted from Figure 6.5.3.1 that the SSB estimates in the majority of ycars in which the Bayesian priors have been applied to maturity at age $(1986,1989,1992,1995)$, appear to be biased towards the egg survey values. This may result from lower expected values for maturity at age in the survey years when compared to the deterministic values of adjacent years. A future development of the model, which should be considered is the use of a density dependent model for maturity.

### 6.5.4 Reliability of the assessment and uncertainty estimation

Posterior distributions for population abundance, natural mortality and spawning biomass in 1997 and 1998 (the latter predicated on an assumption of a catch of $400,000 t$ in 1998) are shown in Figure 6.5.4.1. The distribution of the ratio $\mathrm{F} / \mathrm{M}$ is plotted because as both F and M are uncertain parameters, the distribution of F alone has an uncertain meaning. This shows that:

1. The data and model indicate values of natural mortality higher than 0.12 arc improbable.
2. The lower limit of natural mortality is constrained by the prior assumptions, and the data and model do not give information about this lower limit.
3. Spawning stock size estimates of $945,000 \mathrm{t}$ to $1,420,000 \mathrm{t}$ ( 25 th and 75 th percentiles) in 1997 are calculated.
4. Estimates of the ratio of fishing mortality to natural mortality in 19972.86 to 4.66 ( 25 th and 75 th percentiles) are calculated.
5. The distribution of the estimate of spawning stock biomass in 1983, which has been used for reference purposes, is $838,000 \mathrm{t}$ to $1,030,000 \mathrm{t}$ ( 25 th and 75 th percentiles).

Perceptions of maturity parameter estimates ( $X_{1}$ to $X_{5}$ ) are given in Figure 6.5.4.2. This shows that there is little information in the model and data about these parameters, with the exception that lower values of maturity of the age 4 fish in 1986 appear more likely.

Comparisons between the SSB trajectories from this year's assessment (Figure 6.5.4.3a) with last year's, (Figure 6.5.4.3b) reveal that whereas the 1989,1992 and 1995 surveys were close to the median line last year, the new assessment estimates that they lie between the 75 th and 95 th percentiles. This shows that the assessment results are very sensitive to the egg survey estimate for 1998 and revisions to this when the data are finalised could have a significant effect on the estimated trends in stock size and mortality.

### 6.6 Catch Prediction

A calculation of the consequences of different short-term catch options can be made from the Bayesian assessment, but a different presentation is necessary to take account of the fact that most of the important variables (stock size, natural mortality, fishing mortality etc.) are treated as stochastic. No attempt is made to find a joint maximum-likelihood solution. A stochastic version of the conventional catch option table is presented in Table 6.6.1.

The following assumptions were made in the calculations:

1. Recruitments in 1994 and later were treated as lognormal variates with mean and variance estimated from the mean and variance of the recruitments in 1981, 1983-1986 and 1988-1993. This treatment is as used by ICES (1997/Assess:3) and represents a cautious approach to modelling recruitment as the mean and variance of the weak year classes, ignoring the few stronger year classes.
2. Exploitation in 1998 and later was assumed to follow the selection pattern assumed for 1997.
3. Catches in 1998 were assumed to be $400,000 \mathrm{t}$ (Section 6.8.3). The assumption of $400,000 \mathrm{t}$ in 1998 was thought preferable to an assumption of status quo fishing mortality, because such a mortality would imply much lower catches than those which are expected from this stock.
4. Weights at age in the stock and in the catch, and maturity in years 1998 and later, were taken as the average of the years 1995 to 1997.
5. Options of $\mathrm{F}=\mathrm{M}$, and of Catch $(1999)=$ Catch $(2000)=50,100,200,300$ and 400 thousand tonnes were simulated.
6. In the simulations, an upper bound restriction was placed on fishing mortality $=1.5$, in order to avoid simulations of extreme fishing mortalities when a catch constraint is imposed on a stock size which has a stochastic distribution which may extend to low values (possibly lower than the putative catch constraint).

For each option, the expectation of spawning stock size in 1999 and 2000, and the 25th, 50 th and 75 th percentiles of the SSB distribution are tabulated. The risk that the stock size may fall under each of two reference levels. These reference levels are the model estimate of SSB in 1983 and a value of $500,000 \mathrm{t}$.

Presentation of the $\mathrm{F}=\mathrm{M}$-based option is somewhat complex, as both M and the $\mathrm{F}=\mathrm{M}$ catch are here considered as uncertain. Here, for the $\mathrm{F}=\mathrm{M}$ option, the distribution of corresponding SSB has been tabulated, and also the distribution of the corresponding catch. However, it would be incorrect to interpret the former as being conditional on the expectation of the latter.

### 6.7 Short-Term Risk Analysis and Medium-Term Projections

A calculation of risk was made for some levels of fishing mortality between 0.1 M and 3 M , expressed as the probability of the stock being under $500,000 \mathrm{t}$ at spawning time in 2000 and 2007. This calculation was made from estimates of the probability distribution of spawning stock size using the assumptions given above, but assuming exploitation between 1998 and $2007=0.1 \mathrm{M}, 0.25 \mathrm{M}, \ldots 3 \mathrm{M}$. Risk so calculated is given in Figure 6.7.1.

The outcome of some simple harvest strategies in the medium term was evaluated by taking samples from the multivariate posterior distribution of parameters for the stock assessment, and projecting from each drawn parameter sample under the harvest control from 1999 until 2007.

The assumptions described in Section 6.5 .2 were retained for all cases. The following scenarios were modelled, applying from 1999 onwards:
(1) Constant catch $=50,100,200,300$ or 400 thousand tonnes by year.
(2) Constant fishing mortality $=$ natural mortality.

Some percentiles of the distribution of fishing mortality, recruitment, spawning stock size and landings, calculated under these assumptions, are given in Figures 6.7.2 to 6.7.7.

### 6.8 Comparative Assessment

### 6.8.1 ADAPT maximum-likelihood assessment

An alternative method is the 'ADAPT'-type method (Gavaris, 1988) in which an arbitrary choice of selection pattern is made. This method has been used at earlier Working Group mectings in 1994-1997 to estimate the size of this stock and associated mortality rates. This method is again used at this year's Working Group meeting for comparability with last year's ADAPT assessment and with the Bayesian assessment. The use of the ADAPT method also allows estimation of some of the uncertainty in the assessment, and of the sensitivity of the assessment to the assumed selection pattern. As fishing mortality has histoncally been rather low in this stock, VPA 'convergence' does not help stabilise the analysis rapidly and hence the population model is likely to be strongly dependent on starting assumptions.

The model is a conventional VPA, which is fitted by a non-linear minimisation of the sum of squares with respect to population abundance at age 14 in 1998 subject to the constraints detailed below. Given population abundance N , fishing mortality F , natural mortality M , weights at age W , and maturity at age O , egg survey estimates of SSB U , and the proportion of fishing and natural mortality exerted before spawning PF and PM respectively, the VPA is fitted by minimising:
$\sum_{y}\left(\ln \left(U_{y}\right)-\ln \left(\sum_{a, y} N_{a, y \cdot} O_{a, y \cdot} . W_{a, y} \exp \left(-P F \cdot F_{a, y}-P M \cdot M_{a, y}\right)\right)\right)^{2}$
where subscripts a and y denote age and year respectively.
Given the lack of age-structured surveys it is necessary to impose some constraints about the exploitation pattern on the model. Although some of these constraints are not very realistic there are insufficient observations available to make objective parameter estimations. These constraints are somewhat arbitrary:
a) Selection pattern in 1997 and later years is equal to 1 on ages 4 and older (based on exploratory runs);
b) Selection on ages 0 to 4 in 1995 and later years set to mean from previous 3 years 1994 to 1996 (in last year's assessment a mean over 5 years was used); this change was made to avoid an unreasonably low stock number estimation for the 1996 year class;
c) Natural mortaiity, weights at age in the stock and in the catch are assumed to be known precisely;
d) Maturity ogive is assumed to be known precisely.
e) Fishing mortality on the oldest age taken as an arithmetic mean from age 6 to the penultimate true age in the catch at age matrix.

The choices made about constraints listed above were made after a number of exploratory model fits, which are documented in ICES (1996/Assess:7). As before, egg survey information prior to 1992 was excluded on account of uncertainty introduced by the unknown maturity of the 1982 cohort.

The model is fitted to the traditional egg production estimates of biomass (Table 6.8.1.2d) only for the 1992, 1995 and the preliminary 1998 estimates (which are expected to be approximately $80 \%$ of the 1995 value). Preliminary runs with the ADAPT were made without including an SSB estimate from the 1998 egg survey. These runs resulted in an increase of F to more than 0.5 and a corresponding reduction of the stock size estimation. As this drastic change in stock parameters could not be justified by other information, it was decided to use the preliminary results of the 1998 egg survey for tuning. In general, the output from the ADAPT assessment has shown to be very sensitive on the constraints listed above and the inclusion or exclusion of the 1998 egg survey biomass cstimate.

Input data for the assessment and projections are given in Table 6.8.1.1, fishing mortality, fitted populations, stock sizes and other parameters calculated by the ADAPT procedure are presented in Table 6.8.1.2. In Figure 6.8.1.1 some of these parameters are compared graphically. From Figure 6.8.1.1b it is striking that the VPA fit of SSB (expected) to the SSB estimates from egg surveys (observed) shows a striking discrepancy. This may be caused by invalid assumptions made on the following parameters:

- natural mortality (however, an exploratory run with $M$ reduced to $M=0.05$ improved the fit considerably and brought it very close to the results of the Bayesian analysis, as shown in Figure 6.8.1.3),
- selection pattern, which was presumed to be constant, but might have changed over the last years (and there are indications for this, see Figure 6.4.1.1),
- maturity ogive,
- treatment of the SSB estimates as absolute measures of stock abundance,
- age composition estimates could be biased due to poor sampling coverage,
- the model structure might have been inappropriate.

### 6.8.2 Comparison with GAM egg production estimate

Population parameter estimates obtained using GAM estimates of egg production were presented in the 1996 Working Group report (ICES 1997/Assess:3, Figure 6.2). and the comparison with the traditional estimates was not updated.

### 6.9 Long-Term Yield

Given the uncertainty, both to the mortalities and to the future recruitment, long-term yield has not been computed.

### 6.10 Uncertainty in Assessment

The assessment calculation expressed in Section 6.5 and concomitant forecasts in Sections 6.6 and 6.7 are made with an explicit consideration of perceived uncertainty in natural mortality, egg survey biomass estimates and in maturity parameters for specific ages in the early years of the egg survey. Distribution percentiles for various quantities from the assessment and short-term projection are given in Tables 6.5.3.1 and 6.6.1, which represents the best available estimates of quantified uncertainty.

Additional, unquantified uncertainty exists. The following sources of uncertainty have not been taken into account in the assessment:

- Uncertainty about reported catches;
- Uncertainty about selection pattern assumptions, which have a strong effect on the estimation of recent recruitments;
- Uncertainty in maturity, except for the years and ages mentioned in Section 6.5.2.2. In particular it should be noted from Figure 6.5.3.1 that the SSB estimates in the majority of years in which the Bayesian priors have been applied to maturity at age (1986, 1989, 1992, 1995), appear to be biased towards the egg survey values. This may result from lower expected values for maturity at age in the survey years when compared to the deterministic values of adjacent years. A future development of the model, which should be considered is the use of a density dependent model for maturity, the parameters for which are estimated within the objective function;
- Uncertainty in stock weights and catch weights at age, either for the historic, measured values of for future, projected values;
- Uncertainty in sampling and ageing commercial catches;
- Treatment of the egg survey estimates as absolute measures of stock abundance.

Uncertainty in natural mortality has been incorporated into the model by the use of the Bayesian prior. The posterior distribution has established that within the structure of the model used for the assessment the highest probability of agreement between the estimated SSB and the egg surveys is achieved at the lowest bound of the natural mortality distribution. Although this could be taken as an inference for too high a value of natural mortality, the final natural mortality distribution could be artificially induced by mis-specification of the model structure, specifically - selection at age, maturity at age and/or the use of an absolute scaling for the egg survey estimates.

### 6.11 Reference Points for Management Purposes

### 6.11.1 MBAL

This stock is characterised by infrequent, extremely large recruitments. As only a short time series of data is available, it is not possible to quantify stock-recruit relationships, but one may make the precautionary assumption that the likelihood of a strong year class appearing would decline if stock size were to fall lower than the stock size at which the only such event has been observed. The basis for the level of MBAL is the stock size in 1983 (as estimated by an egg survey and the assessment), which is used as a proxy for the stock size present in 1982; that which produced the strong 1982 year class.

As noted above, population model estimates of the SSB in 1983 differ from the egg survey biomass estimate. The model estimates are in the range 756 to 1281 thousand tonnes with $90 \%$ confidence, yet the egg survey biomass estimate was $530,000 \mathrm{t}$. This year's assessment has not altered the estimate or the confidence limits. However, in Section 6.10 it is noted that the assessment of uncertainty in the population model estimates is incomplete, and therefore it is proposed to retain the use of the egg survey biomass estimate as the reference value for MBAL. Conventionally this has been rounded to $500,000 \mathrm{t}$. The Study Group on the Precautionary Approach to Fisheries Management has accepted this Working Group's recommendation that these values should be used as the SSB reference point $\mathrm{B}_{\mathrm{pa}}$ -

### 6.11.2 Fishing mortality reference points

Given the extreme dynamics of the stock it is inappropriate to attempt to calculate $\mathrm{F}_{\text {msy }}, \mathrm{F}_{\text {med }}$ or $\mathrm{F}_{\text {low }}$ reference points over the time series available. Possibly useful reference points for management purposes might be $\mathrm{F}=\mathrm{M}, \mathrm{F}=2 / 3 \mathrm{M}$ or $\mathrm{F}_{0.1}$. A probability distribution for estimates of $\mathrm{F}_{0.1}$ and $\mathrm{F}_{0.1}$ relative to M from the stock assessment is shown in Figure 6.11.2.1. The percentiles of the distribution $\mathrm{F}_{0.1}$ relative to M are given in the text table below:

| Expected | $5 \%$ | $25 \%$ | $50 \%$ | $75 \%$ | $95 \%$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 1.25 | 1.02 | 1.13 | 1.26 | 1.36 | 1.45 |

This illustrates that even these measures may be problematic as management tools, due to the uncertainty of their estimates in this assessment.

### 6.12 Harvest Control Rules

No harvest control rules were proposed by the Study Group on the Prccautionary Approach to Fisheries Management and none are proposed here. However, the stock is at present in a transition from harvesting the large 1982 year class to the fishing of younger ages. Given the structural uncertainties within the model it was considered that the definition of harvest control rules would be inappropriate. At a later stage, a harvesting strategy will need to be provided, which can be applied when a large year class dominates the stock structure.

### 6.13 Environmental Effects

The Norwegian fishery for horse mackerel is unregulated and is carried out by purse seiners mainly in the Norwegian economical zone in the North Sea in October. This fishery is therefore reflecting the availability of horse mackerel in these areas. There is good correlation between modelled inflow of Atlantic water the first quarter of a year and the Norwegian horse mackerel catches later that year (Iversen et al. 1998). This relation may be used for predictive purposes. Based on the modelled inflow in the winter 1997 a Norwegian catch of $70,000 \mathrm{t}$ was predicted that year. Norway took $46,000 \mathrm{t}$ in 1997, and that was an increase of about $30,000 \mathrm{t}$ since 1996 . The development of the Norwegian fishery for horse mackerel indicates that the stock size has to be above a certain level before it undertakes the migration northwards to the feeding areas and thereby becomes available for the Norwegian purse seiners. Given that the western horse mackerel stock is still above this level, the modelled influx the first quarter of 1998 predicts a Norwegian catch of about $30,000 \mathrm{t}$ this year.

### 6.14 Management Considerations

Given the poor state of knowledge about the long-term dynamics of this stock, the Working Group suggests that management may wish to consider constant fishing mortality options in the range below natural mortality. According to the medium-term predictions (Figures 6.7.1-6.7.7), this will imply a gradual decrease in the risk for the stock of falling below MBAL of $500,000 \mathrm{t}$ in the years immediately after 1998. Both the medium-term projections and comparisons with other stocks suggest that fishing with $\mathrm{F} / \mathrm{M}=1$ would lead to precautionary management. Even in this range, however, it is estimated (based on the assumption of continued low recruitment) that the spawning stock size has a probability around $10 \%$ of falling under MBAL by 2002.

TAC has been overshot considerably since 1988 (ICES 1997/Assess:3). The Working Group advises that if a TAC is set for this stock, it should apply to all areas where western horse mackerel are caught, i.e. Divisions IIa, IIla (western part), IVa, Vb, VIa, VIIa-c, VIIe-k and VIIIa,b,d,e.

## ${ }^{1}$ Provisional.

${ }^{2}$ Includes Sub-area VI.
${ }^{3}$ Includes a negative unallocated catch of $-4,000 \mathrm{t}$.
${ }^{4}$ Includes 5 t from Jersey.

Table 6.5.2.4 Western horse mackerel proportion mature at age.

Table 6.5.3.1 Western Horse Mackerel . Summary results of Bayesian stock assessment.
Percentiles of the distribution of fishing mortality relative to natural mortality (Population mean
fishing mortality over ages 4 to 14 divided by natural mortality), spawning stock size, and
recruitment by year from 1982-1996. Percentiles calculated from 1000 drawn parameter vectors
rom the Markov Chain
a. Fishing Mortality relative to Natural Mortality (F 4-14w/M)

| Percentile | 1982 | 1983 | 1984 | 1985 | 1986 | 1987 | 1988 | 1989 | 1990 | 1991 | 1992 | 1993 | 1994 | 1995 | 1996 | 1997 |

Figure 6.4.1.1 The age composition of the WESTERN HORSE MACKEREL in the international catches from 1982-1997.

Figure 6.5.3.1 Western horse Mackerel. Estimated historic stock trajectories for some population dynamics parameters. Fishing mortality calculated as population-weighted mean over ages 5 to 14 and referenced to natural mortality. Square markers indicate egg survey biomass estimates, $+/-95 \%$ confidence intervals based on $25 \%$ CV. Bold lines, medians. Dashed lines, 25 th and 25 th percentiles. Dotted lines, 5 th and 95th percentiles.

Figure 6.5.4.1. Western Horse Mackerel.Estimates of posterior probability density for some key parameters in the stock assessment.' $F$ ' here is taken as the population-weighted arithmetic mean $F$ from ages 4 to 14 , and is referenced to $M$ because $M$ is a stochastic variable. Distributions calculated from 4000 samples from Markov Chain thinned at intervals of 100 iterations.

Figure 6.5.4.2 Western Horse Mackerel.Estimates of posterior probability density for some parameters of maturity proportions in the stock assessment. See section 6.7.2.2. for description of the expression of maturity in terms of parameters X1-X5

Figure 6.8.1.1 Western Horse Mackerel: Results of the ADAPT-assessment. a.: Total landings; b.: Spawning stock biomass (median, $5^{\text {th }}, 25^{\text {th }}, 75^{\text {th }}$ and $95^{\text {th }}$ percentiles of the expected SSB fitted to SSB estimates from egg surveys) compared to SSB values estimated from egg surveys (as circles; note that the 1998 value is preliminary as there is no final evaluation of this survey available) and the Minimum Biological Acceptable Level (MBAL); c.: Recruitment at age 1; d.: Mean fishing mortality (median, $5^{\text {th }}, 25^{\mathrm{th}}, 75^{\mathrm{th}}$ and $95^{\text {th }}$ percentiles) and means for age groups $5-14$ (unweighted and weighted by stock numbers).

Figure 6.8.1.2 Western Horse Mackerel: Comparison of spawning stock biomass calculated with different assessments (ADAPT vs. Bayesian) and assumptions (excluding or including the 1998 egg survey estimates and using fishing mortalities of either 0.15 or 0.05 ). Circles give SSB values observed at egg surveys, filled ones were used for the ADAPT assessment, open ones were excluded.

Figure 6.11.2.1 Western Horse Mackerel. Estimated posterior probability distribution for F0.1 (upper panel) and for F0.1/M (lower panel).

### 7.1 ACFM advice Applicable to 1997 and 1998

ACFM stated that no management objectives have been articulated. In accordance with the precautionary approach, management objectives should be defined. Biological reference points consistent with these objectives need to be identified and implemented as a basis for advice. Fishing mortality should not be allowed to increase above its recent average (1994-1996) of 0.17 , which is close to $F_{\text {med }}$, corresponding in 1997 to a catch of $53,000 \mathrm{t}$ and in $1998,59,000 \mathrm{t}$. No advice was given for 1997 and the agreed TAC for Divisions VIIIc and IXa is of $56,000 \mathrm{t}$. ICES recommends that the TAC for this stock should only apply to Trachurus trachurus and that other species of horse mackerel be excluded. The present TAC includes catches of other species of horse mackerel.

### 7.2 The Fishery in 1997

Total catches from Divisions VIIIc and IXa were estimated by the Working Group to be $56,770 \mathrm{t}$ in 1997 which represents an increase of $27 \%$ compared with the 1996 catches. The catch by country and gear is shown in Table 7.2.1. The Portuguese catches show an increase of $19 \%$ whereas in the Spanish catches the increase is $31 \%$ compared with the 1996 catches, which represents the highest figure in the last ten years. In 1997 the increase is due to the higher catches obtained by the Spanish purse seiners and to a lesser extent by the Portuguese trawlers and purse seiners. The large rise in the Spanish purse seiners catches can be explained by the falls in abundance in target species, like sardine and anchovy, which has forced to target others like the horse mackerel (Villamor et al., WD 1998). The proportion of the catches by gear presents a similar pattern than in 1996, being the purse seiner catches the most important ones in the Spanish area ( $79 \%$ of the catches) whereas in the Portuguese waters, the trawler's catches are the majority, representing the $56 \%$ of the Portuguese total catch. In 1997 the artisanal Portuguese catches decreased to half of the 1996 catches being the lowest level of the data series.

In this area the catches of horse mackerel are relatively uniform over the year (Borges et al., 1995; Villamor et al., 1996), although the second and third quarters show relatively higher catches than the first and fourth. This is more evident in 1997, possibly due to the predominance of purse seiners catches and the increased effort of this fleet during the spring and summer (see Table 7.2.2).

ICES officially reported catches are requested for "horse mackerel" whose designation includes all the species of the genus Trachurus in the area, not only Trachurus trachurus L . which is the species at present under assessment by this Working Group. The reported catch therefore always has to be revised by the Working Group in order to eliminate species of horse mackerel other than Trachurus trachurus (see Section 1.5).

### 7.3 Biological Data

### 7.3.1 Catch in numbers at age

The catch in numbers at age from all gears for 1997 are presented by quarter and area, disaggregated by Sub-division: VIIIc East, VIIIc West, IXa North, IXa Central North, IXa Central South and IXa South (Table 7.3.1.1). Table 7.3.1.2 and Figure 7.3.1.1 present the catch in numbers by year. The 1982 year class is well represented in the catch in numbers at age matrix. The 1986 and 1987 year classes are strong but do not reach the extreme high level of the 1982 year class. The 1991 and 1992 year classes are shown as strong in the catches as 2, 3 and 4 age-groups diminishing in abundance at age 5 . The abundance in the catches of the 1996 year class at age 1 is also noticeable.

The sampling covers $100 \%$ of the total catch. The number of fish aged seems also to be appropriate, with a total of 3,696 fish aged distributed by quarters. Catch in numbers at age have been obtained by applying a quarterly ALK to each of the catch length distribution estimated from the samples of each Sub-division. The sampling intensity is discussed in Section 1.4. The data before 1985 have not yet been revised according to the approved ageing methodology. So, they have been considered inappropriate for a VPA and have not been included in the analytical assessment.

### 7.3.2 Mean length and mean weight at age

Tables 7.3.2.1 and 7.3.2.2 show the 1997 mean lengths and mean weights at age in the catch by quarter and Sub-division for the Spanish and Portuguese data. Table 7.3.2.3 presents the weight at age in the stock and in the catch. The matrix of mean weights at age in the stock was calculated in the following way: for each age, the mean weight in the catch in the fourth quarter of each year, was averaged with the mean weight in the catch in the first quarter of the following year. Then an average of averages was calculated for the final mean weight estimate.

The data before 1985 have not yet been revised according to the approved ageing methodology and should therefore be considered only correct for ages 0 and 1, ages in which both methods were in agreement.

### 7.3.3 Maturity at age

The proportions of fish mature at each age have been considered to be constant over the assessment period. The maturity ogive used previous to the 1992 assessment (ICES 1993/Assess:7) presented low estimations at the age range 5 to 8 due to less availability of this range of fish on the catches (ICES 1993/Assess:7; ICES 1998/Assess:6). As ACFM requested in 1992 the maturity ogive was smoothed as follows. The Working Group proposes that recent information of maturity at age be analysed and presented next meeting.

| Age Group |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :---: | :---: | :---: | :---: | :---: |
| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |  |  |  |  |  |
| 0.00 | 0.00 | 0.04 | 0.27 | 0.63 | 0.81 | 0.90 | 0.95 | 0.97 | 0.98 | 0.99 | 1.0 | 1.0 |  |  |  |  |  |

### 7.3.4 Natural mortality

According to the ageing methodology established in the ICES area (Eltink and Kuiper, 1989; ICES 1991/H:59) the life span for the southern horse mackerel was considered to be longer. Therefore the natural mortality was revised (ICES 1992/Assess:17), changing the previous level from 0.20 to the present 0.15 . The analytical assessments performed since 1992 have not shown any inconsistency due to this level of natural mortality.

### 7.4 Fishery Independent Information and CPUE Indices of Stock Size

### 7.4.1 Trawl surveys

There are three survey series: The Portuguese July survey, the Portuguese October survey and the Spanish October survey. The two October surveys covered Sub-divisions VIIIc East, VIIIc West, IXa North (Spain) from 20-500 m depth and, Sub-divisions IXa Central North, Central South and South, in Portugal, from $20-750 \mathrm{~m}$ depth. The same sampling methodology was used in both surveys but there were differences in the gear design, as described in ICES (1991/G:13). The Portuguese October and July survey indices and the Spanish September/October survey indices are estimated by strata for the range of distribution of horse mackerel in the area, which has been consistently sampled over the years. This corresponds to the $20-500 \mathrm{~m}$ strata boundaries. It was demonstrated that the horse mackercl off the Portuguese shelf are stratified by length according to the depth and spawning time (ICES 1993/Assess:19). This explains the special characteristics of the composition of the catches, the lower availability of fish after first maturing which creates a peculiar selection pattern.

Table 7.4.1.1 indicates the catch rates from research vessel surveys in Kg per tow, for comparison with the total biomass trend. The biomass index from the Portuguese October survey was shown to be $156 \%$ higher than observed in 1996 only surpassed in the time series by the extremely high value of 1993 biomass index. The series of the Portuguese July survey has a less variability in the data than that of the Portuguese October survey. In 1997 the index is at the mean level of the data series. There was not Portuguese July survey in 1996. The Spanish October survey biomass index indicates a decrease of $46 \%$ compared with the 1996 index. This represents a break in the upward biomass trend that can be observed since 1992.

Table 7.4.1.2 shows the number at age from the Spanish and Portuguese bottom trawl in the October surveys and from the Portuguese July survey. The Spanish September/October survey series is available from 1985 to 1997 and the Portuguese October survey from 1981-1997. Both are carried out during fourth quarter when the recruits have entered the area. In the Portuguese October survey the recruitment (age 0) observed in 1997 was the highest in the data series. On the contrary, in the Spanish area, the index at age 0 from the October survey is the lowest value reached in the series, continuing the low levels obtained since 1995. It seems that there exists no good agreement between these surveys in the abundance index for 0 group. In the Spanish October survey in 1997 the strong 1986 and 1987 year classes were still abundant, a decrease in the yields on the range of ages from 0 to seven years old was evident, changing the pattern observed in 1996 (Table 7.4.1.2). In the Portuguese July survey there is a strong fall in the 1995 and 1997 abundance indices observed in all the ages (except for younger ages in 1997) compared with those obtained in 1994 despite using the same vessel, sampling and gear methodology. The 1982 year class is conspicuous in all the survey series but is stronger in the October Spanish bottom trawl survey.

### 7.4.2 Egg surveys

This was the first series of surveys carried out in the southern area for the Annual Egg Production Method (ICES $1996 / \mathrm{H}: 2$ ). The estimate of 1995 SSB for the southern horse mackerel from those surveys was $261,000 \mathrm{t}$. Data from horse mackerel egg surveys carried out in Spanish and Portuguese waters during 1998 are at present not available. It will be presented to the 1999 Mackerel and Horse Mackerel Egg Surveys Working Group.

### 7.5 Effort and Catch per Unit Effort

Figure 7.5 .1 shows the evolution of the commercial effort series from the Spanish trawl fleets fishing in Sub-division VIIIc West (La Coruña) and in Sub-division VIIIc East (Avilés) from 1984 to 1997. The effort is at the similar low level reached in 1996 although in the Avilés trawl fleet a slight increase of $12 \%$ occurs.

Table 7.5.1 presents the commercial catch rates from the trawl fleet fishing in Sub-divisions IXa Central North, IXa Central South and South (Portugal) from 1979 to 1990 and trawl fleets from Spain fishing in Sub-division VIIIc West (La Coruña) and in Sub-division VIIIc East (Avilés) from 1983 to 1997. A significant decrease in the catch rates of the Spanish trawl fleets, compared with the 1996 levels, occurs, being of $38.5 \%$ and of $25 \%$ for Avilés and La Coruña trawl fleets respectively. The level reached by the trawl fleet operating in Sub-division VIIIc West (La Coruña) is the lowest since 1984. Horse mackerel trawl catch rates from the Portuguese trawl fleet fishing in Division IXa are not available since 1991, because the effort data series is under revision.

## Catch per unit effort at age

CPUE at age from the Galician (La Coruña) bottom trawl fleet (Sub-division VIIIc West) and from the Cantabrian (Avilés) trawl fleet fishing in Sub-division VIIIc East are available from 1984 to 1997.

In the Galician trawl fleet a decrease in the catch rates of the ages in the range between " 0 " group to six years old was observed in 1997. The younger ages are also poorly represented in the Aviles trawl fleet in 1997. The extremely strong 1982 year class is still very prominent in the data for both fleets at age plus group 15 (Table 7.5.2). In 1997, the 1986 and 1987 year classes were confirmed as being strong ones, giving high indices of abundance in both fleets.

### 7.6 Recruitment Forecasting

In 1997 the indices of the 0 group from the surveys carried out in the recruitment season (the Spanish and Portuguese October surveys) are divergent. Again in 1996 the values from the Portuguese October survey were higher (Table 7.4.1.2.). In 1994, the Spanish October survey indicated high recruitment at age 0 and the Portugucse October Survey estimated low recruitment for the 1994 year class. In 1995 both surveys indicated a low level of 0 group abundance which is in agreement with the VPA estimate.

### 7.7 State of the Stock

### 7.7.1 Data exploration and preliminary modelling

All available data were used in the preliminary assessment of this stock. Given the high coherence of the time series and of the previous assessments carried out using Extended Survivors Analysis (XSA), no alternative methods were considered to be used with this stock.

Fishing mortality coefficients were estimated using XSA. In accordance with last year's assessment, the XSA parameters were set at catchability independent of age for ages equal or greater than 9 years old, and the plus group at 12 .

The strength of shrinkage has a significant effect on the standard errors of the log catchability (Anon. 1995/Assess:2). Stronger shrinkage (lower CVs ) increases the standard errors for all fleets. In order to compare the independent information provided by the different fleets, XSA was run separately for each of the fleets, without shrinkage.

The external information used in the tuning was:
Fleet 1: Catch per unit of effort of the trawl fleet from La Coruña (VIIIc West - North Galicia)
Fleet 2: Catch per unit of effort of the trawl fleet from Avilés (VIIIc East - Cantabrian Sea)
Fleet 3: Portuguese October Trawl Survey during the Recruitment season (Division IXa)
Fleet 4: Portuguese July Trawl Survey end of spawning season in Division IXa
Fleet 5: Spanish October trawl Survey during the recruitment season (Sub-division IXa North and Division VIIIc)

The slopes of the linear regressions between log-catchability and log-population were analysed: Fleet 1 , presented a negative slope at age 0 , with a low coefficient of determination, as did Fleet 2, at age 1 with a slightly higher coefficient of determination. These data were plotted and it was decided to not include those ages in the tuning, because they were not providing any information. For Fleet 2 it was considered also appropriate to eliminate the age range $0-4$ because these ages presented very high standard errors. The same procedure was used for Fleet 5, age range 0-4, which did not perform well for young fish. Some ages in Fleets 3 and 4 also presented negative slopes, however, these were not statistically different from zero, hence it wasn't necessary to exclude these ages.

Figure 7.7.1.1 compares the SSB estimated for 1995, 1996 and 1997 by source of independent information. For the year 1995 it is also possible to compare the estimations provided by the fleets with the 1995 egg survey SSB. Low SSB values were estimated from the July surveys and the highest values of SSB correspond to the estimations provided by the Fleet 2 operating in the Cantabrian Sea during all the year. The adults are more abundant in the area during the spawning season when the spawning aggregations occur. The 1995 egg survey estimation indicates a value close to the 1995 SSB estimated by all the fleets and by the October Portuguese survey. The assessment performed and accepted last year indicates a 1995 SSB close to the 1995 egg survey SSB.

Thus the options for the present assessment were taken in accordance with the exploratory analysis, and keeping consistency with last year's assessment.

### 7.7.2 Stock assessment

The final stock assessment was performed following the conclusions of the preliminary modelling (Section 7.7.1). Figure 7.7.2.1 presents the comparison of the Fs of the 1996 and 1997 assessments made with XSA, including all the fleets and a shrinkage of 1.00 . It may be seen that for the reference $F_{\text {bar }}(1-11)$ the estimate shows an extremely close agreement with last year's assessment. Given the pattern of exploitation this stock is subjected to high selection on the younger and older ages and a reduced availability of 4-6 years old fish in the catches. The estimates of $\mathrm{F}_{\mathrm{bar}}(0-3)$ and $\mathrm{F}_{\text {bar }}(7-11)$ also show a very close agreement with last year's assessment.

Figure 7.7.2.2 illustrates the retrospective SSB estimates performed by the final VPA, and the 1995 egg survey estimate, indicating a very good agreement among them.

The tuning diagnostics and final results are given in Tables 7.7.2.1-7.7.2.4. Figure 7.7.2.3 shows the fish stock summary trends over the period 1985-1997 according to the final assessment.

### 7.7.3 Reliability of the assessment and uncertainty estimation

This assessment is very consistent with last year's assessment. The spawning stock biomass estimated from the 1995 egg surveys is in close agreement with the 1995 SSB level estimated using the two October surveys, the July survey information and the two commercial fleets.

### 7.8 Catch Predictions

The terminal population in 1997 from the final VPA was used as input to the catch forecast for age groups 1 and older. Recruitment at age 0 was assumed to be the geometric mean of the period 1985-1994. The exploitation pattern was taken as the arithmetic mean of the last three years, without scaling to the last year, which is assumed to correspond to the most likely exploitation in the short term. Table 7.8 .1 gives the input parameters and Tables 7.8.2.a-c and Figure 7.8.1 show the results of the short-term predictions of the catch and spawning stock biomass.

At $\mathrm{F}_{\text {status quo }}\left(\mathrm{F}_{\text {bar }} 95-97\right.$ ) the predicted catch in weight for 1998 is $55,771 \mathrm{t}$. In 1999, assuming the same recruitment level, the catch at $F_{\text {status quo }}$ is predicted to be $58,479 \mathrm{t}$. The spawning stock biomass is predicted to decrease from $262,730 \mathrm{t}$ at the beginning of 1998 to $249,221 \mathrm{t}$ in 1999 at $\mathrm{F}_{\text {status quo, }}$, and to $249,061 \mathrm{t}$ if the TAC of $56,000 \mathrm{t}$ is taken in 1998. The spawning stock biomass is predicted to decrease in 2000 , at $\mathrm{F}_{\text {staus quo }}$ to $239,545 \mathrm{t}$.

### 7.9 Short-Term Risk Analysis

A sensitivity analysis was performed on our short-term catch predictions using the methodology and software by Cook (1993). The results of this analysis are shown in the plots of Figure 7.9.1. The values plotted in the barplots are proportional to the influence of each parameter on the final value of the variables of interest: the yield in 1999 and the SSB in 2000 (a list of the parameters is given in Table 7.9 .1 and their input values are in Table 7.9.2). The pies on the right side of Figure 7.9.1 show the relative percentages of the same values.

The plot at the top of Figure 7.9 .2 describes the probability of $F(1999)$ being higher than $F_{\text {satus que }}$, given several values of yield for 1999. It can be seen that for a catch of approximately $60,000 \mathrm{t}$ in 1999 , the $\mathrm{F}(1999)$ has a 0.5 probability of becoming higher than $\mathrm{F}_{\text {satus quo. The plot at the bottom of Figure } 7.9 .2 \text { shows the probability of the SSB in } 2000 \text { being }}$ lower than a given value (in abscissa) assuming $F_{\text {status quo }}$ for the whole period (1998-2000). At present we have about 0.5 probability of SSB in 2000 being lower than $225,000 \mathrm{t}$.

The probabilities shown in Figure 7.9 .2 were calculated by the method of Cukier et al. (1978), in which values for the state variables are repeatedly calculated introducing periodic disturbances in the parameters. Empirical distributions of the state variables are then obtained, from which the variability due to each parameter can be estimated by Fourier analysis.

### 7.10 Medium-Term Predictions

Medium-term predictions were carried out using the software WGTERMA (ICES 1994/Assess:6). Predictions were made assuming stochastic recruitment and uncertainty in the initial population sizes. 500 simulations were performed. Figure 7.10 .1 shows from left to right and top to bottom the stock-recruitment plot, the evolution of the yield, of the recruitment and of the SSB assuming $\mathrm{F}_{\text {staus quo }}$ till 2007. The dotted line represents the average and solid lines the 5,10, 20,50 and 95 percentiles.

Figures 7.10.2 and 7.10.3 show the predicted values of SSB until 2000 and until 2007 assuming different Fs. F-factor
 All three reference points present relatively similar values. $B_{p a}$ and $B_{\text {loss }}$ are also represented in these figures as solid parallel lines. $B_{p a}$ was defined as $206,000 \mathrm{t}$ (see Section 7.12), corresponding roughly to the minimum observed SSB, if we exclude one extreme observation that is placed far from the cloud of points (see top-left plot in Figure 7.10.1). $\mathrm{B}_{\text {loss }}$ was defined as $136,000 \mathrm{t}$, corresponding to the lowest $\operatorname{SSB}$ observed considering all points of the SSB-recruitment plot.

### 7.11 Long-Term Yield

The long-term yield per recruit and spawning biomass-per-recruit curves, against $F$, derived using the input data in Table 7.8.1 are shown in Figure 7.8.1. Table 7.11 .1 presents the yield per recruit summary table. $\mathrm{F}_{0.1}$ is estimated to be 0.09 , and $F_{\text {max }}$ to be 0.17 , at the reference age (1-11).

### 7.12 Reference Points for Management Purpose

The reference points were estimated using the PA software (CEFAS, Lowestoft). The estimated $F_{\text {med }}$ value is 0.165 and $F_{\text {high }}$ corresponds to 0.26 (see Figure 7.12.1). The present level of $F_{\text {status quo }}$ of 0.18 is above the $F_{\text {med }}$ level and $F_{\text {max }}$ which is 0.17 .

As can be seen from Figure 7.12.2, the range of SSBs is quite narrow, and no stock-dependent trend in the recruitment can be inferred from these observations. The extremely strong 1982 year class has contributed substantially to the SSB during the whole period 1985-1997. The lowest biomass attained during the period was $130,000 \mathrm{t}$ in 1985, which originated a medium recruitment. $F_{\text {loss }}$ is 0.27 , well above $F_{\text {max }}$ and $F_{\text {med }}$.

Last year this Working Group proposed $\mathrm{F}_{\mathrm{max}}$ as $\mathrm{F}_{\mathrm{pa}}$. This was further supported by the Study Group on the Precautionary Approach to Fisheries Management (ICES 1998/ACFM:10). Our present results do not suggest any changes for this recommendation.
$B_{\text {tim }}$ is defined as $B_{\text {loss }}$ which corresponds to be $136,300 t$, the lowest SSB in the series. $B_{p a}$ is considered as $B_{\text {loss }} e^{1.645 \text { o }}$ that corresponds to $206,000 \mathrm{t}$.

### 7.13 Harvest Control Rules

No harvest control rules were proposed neither by the Study Group on the Precautionary Approach to Fisheries Management (ICES 1998/ACFM:10) nor by this Working Group.

### 7.14 Management Considerations

The predicted evolution of this stock in terms of $\mathrm{SSB}, \mathrm{F}_{\mathrm{lim},}, \mathrm{F}_{\mathrm{pa}}, \mathrm{B}_{\mathrm{lim}}$ and $\mathrm{B}_{\mathrm{pa}}$ is shown in Figure 7.14.1. Table 7.14.1 summarises several management options at: $\mathrm{F}_{\text {status quo }}, \mathrm{F}$ constrained to the official TAC of $56,000 \mathrm{t}, \mathrm{F}$ corresponding to TAC 1998, $\mathrm{F}_{\text {med }}$ and $\mathrm{F}_{\text {max }}\left(=\mathrm{F}_{\mathrm{pa}}\right)$.

In 1997, F attained a value considerably higher than $\mathrm{F}_{\mathrm{pa}}$ ( $\mathrm{F}_{97}=0.22$ ). In order to prevent future increase of the fishing mortality two measures should be put in practice: a reduction of TAC to $52,000 \mathrm{t}$, which corresponds to $\mathrm{F}_{\mathrm{pa}}$, and a reduction of fishing effort. Taking into account that $F_{\text {status quo }}$ is 0.175 and $F_{p a}$ is 0.165 , an increase of the fishing effort should be avoided.

The Working Group also considers that the TAC should not be applied to all Trachurus species combined but only to Trachurus trachurus.

Table 7.2.1 Annual catches (tonnes) of SOUTHERN HORSE MACKEREL by countries by gear in Divisions VIIIc and IXa. Data from 1984-1996 are Working Group estimates.

| Year | Portugal (Division IXa) |  |  |  | Spain (Divisions IXa + VIIIc) |  |  |  |  | $\begin{gathered} \text { Total } \\ \text { VIIIc }+ \text { IXa } \end{gathered}$ |
