## PREFACE

Annual catch quotas and other regulations of the Barents Sea fisheries are set through negotiations between Norway and Russia. Assessment of the state of the stocks and quota advices are given by the International Council for the Exploration of the Sea (ICES). Their work is based on survey results and the international landings statistics. The results from this demersal fish winter survey in the Barents Sea are an important source of information for the annual stock assessment.

These surveys started in the mid 1970-ies, focused on acoustic measurements of cod and haddock. Since 1981 the survey has been designed to give both acoustic and swept area estimates of fish abundance. Some development has taken place since then, both in terms of area coverage and in terms of methodology. The development is described in more detail by Jacobsen et al. (1997). At present this survey provides the main data input for a number of projects at Institute of Marine Research, Bergen:

- monitoring abundance of the Barents Sea demersal stocks
- mapping fish distribution in relation to climate and prey abundance
- monitoring food consumption and growth
- estimating predation mortality caused by cod

This report presents the results from the survey in February 2002. This year the Russian research vessel "Persey 3" participated in addition to the Norwegian research vessels "G.O. Sars" and "Johan Hjort". The total duration of the survey was from 28 January to 04 March. One scientist from PINRO, Murmansk, participated onboard "Johan Hjort".

## SUMMARY

A combined acoustic and bottom trawl survey to obtain indices of abundance and estimates of length and weight at age has been carried out each winter (4-6 weeks in January- March) since 1981 in the Barents Sea. The target species are cod and haddock, but in recent years abundance indices have also been worked out for the redfish species and Greenland halibut. Since 1993 the survey area has been extended to the north and east in order to obtain a more complete coverage of the younger age groups of cod. In winter 1997 only the Norwegian part of the Barents Sea and a small part of the Svalbard area was covered, while in 1998 also a small part of the Russian EEZ was covered. In 1999 and 2000 the Norwegian vessels had full access to the Russian EEZ. In 2001 and 2002 a Russian research vessel covered most of the areas where the Norwegian vessels did not have access, and a sufficient coverage was obtained.

The main results in 2002 were:

- the 2001 year class of cod is very weak and the 2000 year class is indicated to be somewhat below average. The 1999 and 1998 year classes is slightly higher than expected from last years survey
- the abundance indices of 5-8 year old cod (1997-1994 year classes) are as expected from the last years survey
- the numbers of 9 year and older cod are very low
- lengths and weights at age and weight increments are similar to those observed in 2001, while some increase was observed from 2000 to 2001.
- the mortality rate has been reduced compared with the previous years for age group 6 and younger, while it has remained high for older age groups
- for haddock all the year classes 1998, 1999, 2000 and 2001 are indicated to be at or above average. The 1996 year class is below average, but considerably larger than the year classes 1992-1995, which are very weak.
- length and weight at age and weight increment seem to have stabilized, after a period of increase over the years 1998-2000.
- the abundance indices of the redfish species are among the lowest in the time series and there are no signs of improved recruitment
- compared to the 2001-results the abundance indices of Greenland halibut in the size range 15 to 44 cm have decreased, while they have increased for the other size groups.

## 1. INTRODUCTION

The Institute of Marine Research (IMR), Bergen, has performed acoustic measurements of demersal fish in the Barents Sea since 1976. Since 1981 a bottom trawl survey has been combined with this acoustic survey. The survey area was extended in 1993. Since then the typical effort of the combined survey has been 10-14 vessel-weeks, and about 350 bottom trawl hauls have been made each year. Most years 3 vessels have participated from about 1 February to 1 March.

The purpose of the investigations is:

- Obtain acoustic abundance indices of cod, haddock and redfish
- Obtain swept area abundance indices by length (and age) groups of cod haddock, redfish and Greenland halibut.
- Map the geographical distribution of those fish stocks
- Estimate length, weight and maturity at age for those stocks
- Collect stomach samples from cod as a basis for estimating predation by cod

The results and the collected data are used both in the ICES stock assessments and by several research projects at IMR and PINRO.

In the early 1990-ies the cod distribution area increased both due to improved climate and increasing stock size. In 1993 the survey area therefore was increased, and since then the survey has been aimed towards covering the whole cod distribution area outside the ice-border. In 1997 and 1998 the Norwegian research vessels were not allowed to cover the Russian EEZ, and in 1999 the coverage was partly limited by a rather unusually wide ice-extension. Adjustments, associated with large uncertainties, are applied to the estimates in 1997 and 1998 to compensate for the lack of coverage. The results for those years may therefore not be comparable to the results for other years. Since 2000 Russian research vessels have participated in the survey and the coverage have been far better then in the years 1997-1999.

## 2. METHODS

### 2.1 Acoustic measurements

The method is explained by Dalen and Smedstad (1979, 1983), Dalen and Nakken (1983), MacLennan and Simmonds (1991) and Jakobsen et al. (1997). The acoustic equipment has been continuously improved. Since the early 1990-ies a Simrad EK500 echo sounder and Bergen Echo Integrator (BEI, Knudsen 1990) has been used. In the mid 1990-ies the echo sounder transducers were moved from the hull to a protrudable centreboard. This latter change has largely reduced the signal loss due to air bubbles close to the ship's hull.

Acoustic backscattering values $\left(\mathrm{s}_{\mathrm{A}}\right)$ are stored at high resolution in the BEI-system. After scrutinizing and allocating the values to species or species groups, the values are stored with 10 m vertical resolution and 1 nautical mile horizontal resolution. The procedure for allocation by species is based on:

- composition in trawl catches (pelagic and demersal hauls)
- the appearance of the echo recordings
- inspection of target strength distributions

For each trawl catch the relative $\mathrm{s}_{\mathrm{A}}$-contribution from each species is calculated (Korsbrekke 1996) and used as a guideline for the allocation. In these calculations the fish length dependent catching efficiency of cod and haddock in the bottom trawl (Aglen and Nakken 1997) is taken into account. If the trawl catch gives the true composition of the species contributing to the observed $\mathrm{s}_{\mathrm{A}}$ value, those catch-based $\mathrm{s}_{\mathrm{A}}$-proportions could be used directly for the allocation. In the scrutinizing process the scientists have to evaluate to what extent these catch-based $\mathrm{s}_{\mathrm{A}}$ proportions are reasonable, or if they should be modified on the basis of knowledge about the fish behaviour and the catching performance of the gear.

## Estimation procedures

The area is divided into rectangles of $1 / 2^{\circ}$ latitude and $1^{\circ}$ longitude. For each rectangle and each species an arithmetic mean $\mathrm{s}_{\mathrm{A}}$ is calculated for the demersal zone (less than 10 m above bottom) and the pelagic zone (more than 10 m above bottom). Each of those acoustic densities by rectangle are then converted to fish densities by the equation:

$$
\begin{equation*}
\bar{\rho}_{A}=\frac{\bar{s}_{A}}{\bar{\sigma}_{A}} \tag{1}
\end{equation*}
$$

$\bar{\rho}_{A}$ is average fish density (number of fish / square n.mile) by rectangle
$\bar{s}_{A}$ is average acoustic density (square $\mathrm{m} /$ square n.mile) by rectangle $\bar{\sigma}_{A}$ is average backscattering cross-section (square m) by rectangle

For cod, haddock and redfish the backscattering cross-section ( $\sigma$ ), target strength (TS) and fish length ( L cm ) is related by the equation (Foote, 1987):

$$
\begin{equation*}
\mathrm{TS}=10 \cdot \log \left(\frac{\sigma}{4 \pi}\right)=20 \cdot \log (L)-68 \tag{2}
\end{equation*}
$$

From 1992 onward the following target strength function has been applied for cod, haddock and redfish:
$\mathrm{TS}=21.8 \cdot \log (L)-74.9$

The data for the period 1981-1992 has been recalculated (Aglen and Nakken 1997) for taking account of:
-changed target strength function
-changed bottom trawl gear (Godø and Sunnanå 1992)
-size dependant catching efficiency for cod and haddock (Dickson 1993a,b).

In 1999 some errors in the time series were discovered and corrected (Bogstad et al. 1999). Those errors related to cod for the years 1983-1998 and for haddock for the years 1985-1998.

Combining equations 1,2 and 3 gives:

$$
\begin{equation*}
\bar{\rho}_{A}=5.021 \cdot 10^{5} \cdot \bar{s}_{A} / \bar{L}^{2} \tag{3}
\end{equation*}
$$

$\vec{L}^{2}$ is average squared fish length by rectangle and by depth channels (i.e., pelagic and bottom)

As a basis for estimating $\overline{L^{2}}$ trawl catches considered to be representative for each rectangle and depth zone are selected. (Anon. 1998). This is a partly subjective process, and in some cases catches from neighbouring rectangles are used. Only bottom trawl catches are used for the demersal zone. Obtaining a sufficient number of useful pelagic catches requires huge effort, and uncertainties concerning the fish behaviour relative to the pelagic trawl often lead to doubts about the representativity of the pelagic catches. Therefore, both pelagic and bottom trawl catches are applied to the pelagic zone. Length frequency by 5 cm length groups form the basis
for calculating mean squared length. The bottom trawl catches are normalised to 1 nautical mile towing distance and adjusted for length dependant fishing efficiency (Aglen and Nakken 1997, see below). Pelagic catches are applied unmodified.

Let $f_{i}$ be the (adjusted) catch by length group $i$ and let $L_{i}$ be the midpoint ( cm ) of the length interval $i$. Then:

$$
\begin{equation*}
\bar{L}^{2}=\frac{\sum_{i=i_{\text {inin }}}^{i_{\text {max }}} f_{i} \cdot L_{i}^{2}}{\sum_{i=i_{\text {min }}}^{i_{\text {max }}} f_{i}} \tag{4}
\end{equation*}
$$

For each species the total density $\left(\bar{\rho}_{A}\right)$ by rectangle and depth zone is calculated by equation (3). This total density is then split on length groups according to the estimated length distributions. These densities are further converted to abundance by multiplying with the area of the rectangle. The estimated abundance by rectangle is then added for defined main areas (Figure 3.2). Estimates by length are converted to estimates by age by using an age length key for each main area derived from the age sampling during the survey.

### 2.2 Swept area measurements

All vessels were equipped with the standard research bottom trawl Campelen 1800 shrimp trawl with 80 mm (stretched) mesh size in the front. Until and including 1993 a cod-end with 35-40 mm (stretched) mesh size and a cover net with 70 mm mesh size were used. Since this mesh size may lead to considerable escapement of 1 year old cod, the cod ends were in 1994 replaced by cod-ends with 22 mm mesh size. At present a cover net with 116 mm meshes is mostly used. The ground gear has also been changed during the time series. The trawl is now equipped with a rockhopper ground gear. Until and including 1988 a bobbins gear was used, and the cod and haddock indices from the time period 1981-1988 have since been recalculated to 'rockhopper indices' and adjusted for fish length dependent fishing or sweep width (Godø and Sunnanå 1992, Aglen and Nakken 1997). The sweep wire length is 40 m , plus 10 m wire for connection to the doors. Vaco doors $\left(6 \mathrm{~m}^{2}, 1500 \mathrm{~kg}\right)$, which are considered to be the best compromise when doing both pelagic and bottom trawling, have earlier been used as standard trawldoors on board the research vessels. On hired vessels V-type doors (ca $7 \mathrm{~m}^{2}$ ) have been used. In 2001, R/V "Johan Hjort" and R/V "G.O.Sars" used Vaco doors ( $6 \mathrm{~m}^{2}$, 1500kg), while R/V "Persey 4" used a V-type door ("Steinshamn W-9", $7.1 \mathrm{~m}^{2}, 2050 \mathrm{~kg}$ ). In order to achieve constant sampling width of a trawl haul independent of e.g. depth and wire length, a 10 m rope "locks" the distance
between the trawl wires $150-180 \mathrm{~m}$ in front of the trawl doors. This is called "strapping". The distance between the trawl doors then become almost constant of 48-52 m (Engås and Ona 1993, Engå 1995). The trawl's catchability of different species and length groups then becomes independent of bottom depth. Without strapping, the distance between the doors is $50-$ 60 m and increasing with increasing wire length, and thereby with increasing depth. In 1993 strapping was used on board the research vessels, in 1994 on every third haul, in 1995-1997 on every second haul on all vessels, and since 1998 on all hauls when weather conditions allow for it. Standard tow duration is 30 minutes (until 1985 the tow duration was 60 min .). On all trawl stations the trawl performance is constantly monitored by Scanmar trawl sensors, i.e., distance between the doors, vertical opening of the trawl and bottom contact control.

The geographical position of the trawl stations are pre-defined and kept fixed from year to year. When the swept area investigations started in 1981 the investigated area was divided into four main areas ( $\mathrm{A}, \mathrm{B}, \mathrm{Cog} \mathrm{D}$ ) and 35 strata (smaller and, by experience, more uniform biotops). During the first years the number of trawl stations in each stratum was set based on expected fish distribution in order to reduce the variance, i.e., more hauls in strata with high and variable fish density. In recent years the trawl stations have been spread out more evenly, although the distance between stations in the central cod distribution area is shorter ( 20 n.miles) compared to the more marginal areas ( 30 n .miles). In 2001 the strata close to the Finnmark coast was covered by a 15 n.mile grid. Considerable amounts of young cod were during the 1990-ies distributed outside the initial four main areas, and in 1993 the investigated area was therefore enlarged by areas D', E, and the ice-free part of Svalbard (S) (Fig. 3.2 and Table 3.1), altogether 28 new strata. In the 1993- and 1994 survey reports, the Svalbard area was included in A' and the western (west of $30^{\circ} \mathrm{E}$ ) part of area E. Since 1996 a revised strata system with 23 strata has been used (Figure 2.1). The main reason for reducing the number of strata was the neccessity to get a sufficient number of trawl stations in each stratum to get reliable estimates of density and variance.

Figure 2.1 Strata (1-23) and Main Areas (A,B,C,D,D',E and S) used for swept area estimations. The Main Areas are also used for the acoustic estimation.

## Swept area fish density estimation

Swept area fish density estimates $\left(\rho_{s, l}\right)$ by species $(s)$ and length $(l)$ were estimated for each bottom trawl haul by the equation:

$$
\rho_{s, l}=\frac{f_{s, l}}{a_{s, l}}
$$

$\rho_{s, l}$ number of fish of length $l$ per n.m. ${ }^{2}$ observed on trawl station $s$
$f_{s, l}$ estimated frequency of length $l$
$a_{s, l}$ swept area:

$$
a_{s, l}=\frac{d_{s} \cdot E W_{l}}{1852}
$$

$d_{s}$ towed distance (n.mile)
$E W_{l}$ length dependent effective fishing width:

$$
\begin{aligned}
& E W_{l}=\alpha \cdot l^{\beta} \text { for } l_{\min }<l<l_{\max } \\
& E W_{l}=E W_{l_{\min }}=\alpha \cdot l_{\min }^{\beta} \text { for } l \leq l_{\min } \\
& E W_{l}=E W_{l_{\max }}=\alpha \cdot l_{\max }^{\beta} \text { for } l \geq l_{\max }
\end{aligned}
$$

The parameters are given in the text table below:

| Species | $\boldsymbol{\alpha}$ | $\boldsymbol{\beta}$ | $\boldsymbol{l}_{\min }$ | $\boldsymbol{l}_{\max }$ |
| :--- | :--- | :--- | :--- | :--- |
| Torsk | 5.91 | 0.43 | 15 cm | 62 cm |
| Hyse | 2.08 | 0.75 | 15 cm | 48 cm |

The fishing width was previously fixed to $25 \mathrm{~m}=0.0135 \mathrm{~nm}$. Based on Dickson (1993a,b), length dependent effective fishing width for cod and haddock was included in the calculations in 1995 (Korsbrekke et al., 1995). Aglen and Nakken (1997) have adjusted both the acoustic and swept area time series back to 1981 for this length dependency based on mean-length-at-age information. In 1999, the swept area 1983-1995 time series was recalculated for cod and haddock using the new area and strata divisions (Bogstad et al. 1999).

For redfish, Greenland halibut and other species, a fishing width of 25 m was applied, independent of fish length.

Observations of fish density by length are summed together in 5 cm length-groups $\rho_{s, l}$ where $l$ is the length-group. Stratified indices by length-group and stratum will then be:

$$
L_{p, l}=\frac{A_{p}}{S_{p}} \cdot \sum_{s \text { in stratum } p} \rho_{s, l}
$$

$L_{p, l}$ index, stratum $p$, length-group $l$
$A_{p} \quad$ area (n.m. ${ }^{2}$ ) of stratum $p$ (or the part of the stratum covered by the survey) $S_{p}$ number of trawl stations in stratum $p$

The coverage of the northern- and easternmost strata differs from year to year. The strata area is therefore recalculated when necessary by multiplying the total stratum area by the ratio of trawl stations taken. Indices are estimated for each stratum within the main areas A, B, C, D, D', E and S. Total number of fish in each 5 cm length group in each main area is estimated by adding all strata within the area. Total number of fish at age is estimated by using an age-length key constructed for each main area. Total indices on length and age are estimated adding all main areas.

### 2.3 Sampling of catch and age-length keys.

Sorting, weighing, measuring and sampling of the catch are done according to instructions given in Fotland et al. (1997). Since 1999 all data except age are recorded electronically by Scantrol Fishmeter, a measuring board connected to stabilized scales. The whole catch or a representative sub sample of most species was length measured on each station.

On each bottom and pelagic trawl station age (otoliths) and stomach were sampled from 1 cod per 5 cm length-group. All cod above 90 cm were sampled. The stomach samples were frozen and analysed after the survey. From haddock age was sampled from 1 specimen per 5 cm lengthgroup. Regarding the redfish species, Sebastes marinus and S. mentella, otoliths for age determination were sampled from 2 fish in every 5 cm length-group on every station. This regular sampling was supplemented with extra samples from hauls with big redfish catches. Greenland halibut were sorted by sex before length measurement and age (otolith) sampling. From this species otoliths were collected from 5 fish per 5 cm length group for each sex on all stations. Table 3.2 gives an account of the sampled material.

One age-length key is constructed for each main area. All age samples are included and weighted according to:

$$
w_{p, l}=\frac{L_{p, l}}{n_{p, l}}
$$

$w_{p, l}$ - weighting factor
$L_{p, l}$ - swept area index of number fish in length-group $l$ in stratum $p$
$n_{p, l}$ - number of age samples in length-group $l$ and stratum $p$

Fractions are estimated according to:

$$
P_{a}^{(l)}=\frac{\sum_{p} n_{p, a, l} \cdot w_{p, l}}{\sum_{p} n_{p, l} \cdot w_{p, l}}
$$

$p_{a}^{(l)} \quad$ - weighted fraction of age $a$ in length-group $l$ and stratum $p$
$n_{p, a, l}$ - number of age samples of age $a$ in length-group $l$ and stratum $p$

Number of fish by age is then estimated following the equation:

$$
N_{a}=\sum_{p} \sum_{l} L_{p, l} \cdot P_{a}^{(l)}
$$

Mean length and -weight by age is then estimated according to (only shown for weight):

$$
\begin{gathered}
W_{a}=\frac{\sum_{p} \sum_{l} \sum_{j} W_{a, p, l, j} \cdot w_{p, l}}{\sum_{p} \sum_{l} \sum_{j} w_{p, l}} \\
W_{a, p, l, j}-\text { weight of sample } j \text { in length-group } l, \text { stratum } p \text { and age } a
\end{gathered}
$$

## 3. SURVEY OPERATION

The survey in 2002 was conducted with R/V "G.O. Sars" 30.01-04.03 (IMR-BEI-survey no. 2002002, IMR-series no. 80001-80167 and 80853 and 8860), R/V "Johan Hjort" 29.01-03.03 (IMR-BEI-survey no. 2002202, IMR-series no. 80201-80365), and R/V "Persey 3" from PINRO 31.01-25.02. The catch data and biological samples from R/V "Persey 3 " were converted to the IMR-format "Regfisk" (IMR-series no. 80401-80529). The acoustic data from R/V "Persey 3" was reported to IMR as allocated values by species at 5 n.mile intervals, split on a bottom layer ( $<10 \mathrm{~m}$ from bottom) and a pelagic layer ( $>10 \mathrm{~m}$ above bottom).

Fig. 3.1 shows survey tracks and trawl stations, and fig. 3.2 shows the survey area with the main areas A, B, C, D, D', E and S (part of the Svalbard area). Table 3.1 shows the area in square n.miles of each main area covered by the survey every year. In the 2002 survey 254 hydrographical (CTD) stations and 463 trawl stations were taken (fig. 3.1, table 3.2). 19 of the trawl stations were pelagic trawl hauls using Åkrahamn pelagic trawl ( 3200 mm mesh size in front and 20 mm in the cod end; see Valdemarsen and Misund 1995) in order to get more samples and information to improve the echo scrutinizing by species and fish length. For the calculation of swept area indices, only the successful pre-defined bottom trawl stations were used. Those added up to 399 stations. There were 45 additional stations, not used in the swept area calculation; 14 unsuccessful hauls (either damage or malfunction of the gear), 2 nonpredefined hauls for identification of acoustic records, 12 outside the strata system defined in Figure 2.1 (1 NE of Bear Island and 11 close to the Murman coast), and 17 taken for a special study in the "Grey Zone". Age sampling from these additional bottom trawl hauls and from pelagic hauls has been used in the calculations, as long as they were taken within the defined strata system.

Table 3.2 gives an account of the sampled length- and age material from pre-defined bottom trawl hauls, other bottom hauls and pelagic hauls.

One scientist from PINRO, Murmansk, participated onboard "Johan Hjort" as long as the vessels were working in Russian EEZ.

Table 3.1. Area (n.miles ${ }^{2}$ ) covered in the bottom trawl surveys in the Barents Sea winter 1981-2002.

|  | Main Area |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## 4. HYDROGRAPHY

Measurements of temperature and salinity where recorded for the whole water column on most of the pre-defined trawl stations.

Fig. 4.2 shows the drift ice border and temperature distribution close to surface, at 100 m depth and at the bottom. The Barents Sea was slightly colder in 2002 compared to the year before.

The standard hydrographical sections "Fugløya-Bjørnøya" and "Vardø-north" taken at a Norwegian survey one or two weeks after the fish survey, showed moderate changes in mean temperature at 50-200 m depth, compared to the period 1999-2001. The Sem Islands section was only partly covered in 2002. This section was not covered in the 1997-1999.

Fig.4.1. Mean temperatures in 50-200 m depth in 1977-2002. A) "Fugløya-Bjørnøya" in March, B) "Vardø-Nord" in March, C) Sem Islands in January-February.

Figure 4.2. Temperature distribution February 2002. A) surface, B) 100 m depth, C) bottom.

## 5. TOTAL ECHO ABUNDANCE OF COD AND HADDOCK

The geographical distributions of total echo abundance of cod and haddock are shown in fig. 5.1 and 5.2, respectively, where also the drift ice border is drawn. The distribution of cod was similar to the previous year. Very scattered recordings of cod were observed over most of the area covered by the survey, while the areas with dense recordings were quite limited.

Haddock had a wider distribution to the north than usual. The densest recordings were observed from Skolpen Bank to the Murman coast and east of Fugløy Bank.

Table 5.1 shows the echo abundance (echo density multiplied by area) distributed on main areas as well as on pelagic versus bottom channels. Compared to the 2001 survey (Aglen et al. 2002) the echo abundance of cod was rather similar in all main areas. The total value for cod has decreased by $7 \%$. For haddock there was an increase in all main areas, except D', and the total value increased by $62 \%$. For redfish there was a decrease in all areas, and the total value decreased by $60 \%$.

Table 5.2 presents the time series of total echo abundance of cod and haddock in the investigated areas. The 2002 value for cod is above those from 1997 and 1999, but considerably below the values observed in the mid 90 -ies. The value for haddock is the fourth highest among the ten latest years. The relative echo abundance for cod in the bottom channel ( $0-10 \mathrm{~m}$ above bottom) was $32 \%$, which is close to the year before, but somewhat higher than in the years 1998-2000. The percentage of haddock in the bottom zone was 20, which is much less than in 2001 (43\%), but not far from the average for the last ten years.

Figure 5.1. COD. Distribution of total echo abundance winter 2002. Unit is area back scattering surface $\left(\mathrm{s}_{\mathrm{A}}\right)$ per square nautical mile $\left(\mathrm{m}^{2} / \mathrm{n}\right.$. mile $\left.{ }^{2}\right)$.

Figure 5.2. HADDOCK. Distribution of total echo abundance winter 2002. Unit is area back scattering surface $\left(\mathrm{s}_{\mathrm{A}}\right)$ per square nautical mile $\left(\mathrm{m}^{2} / \mathrm{n}\right.$. mile $\left.^{2}\right)$.

Table 5.1. Echo abundance of cod, haddock and redfish in the pelagic layer $(\mathrm{P})$ and in the 10 m layer above the bottom (B) in main areas of the Barents Sea winter $2002\left(\mathrm{~m}^{2}\right.$ reflecting surface $\left.\cdot 10^{-3}\right)$.

## 6. DISTRIBUTION AND ABUNDANCE OF COD

### 6.1 Acoustic estimation

Surveys in the Barents Sea at this time of the year mainly cover the immature part of the cod stock. Most of the mature cod (age 7 and older) have started on its spawning migration southwards out of the investigated area, and is therefore to a lesser extent covered.

Acoustic indices by length and age are given in table 6.1. Table 6.2 shows the acoustic indices for each age group by main areas, in the pelagic layer ( P ) and in the 10 m layer above the bottom (B).

The time series (1981-2002) is presented in table 6.3. The indices for 1997 and 1998 are raised to also represent the Russian EEZ. Indices for the Russian EEZ in 1997 and 1998 were calculated by interpolation of the ratios found in the Russian EEZ in 1996 and 1999, age group by age group.

Since the coverage of the Svalbard area ( S ) varies from year to year due to ice, this area has been excluded in the extrapolation of fish abundance in the Russian EEZ in 1997-1998, and just added to the total index afterwards.

The indices for ages 1 and 3 are the lowest estimated since the survey area was extended in 1993. For age 2 the index is $58 \%$ of the 1993-2001 average, and for age 4 it is $68 \%$ of that average. For ages 5-7 the indices are close to the 1993-2001 average.

Table 6.1. COD. Abundance indices at length and age from the acoustic survey in the Barents Sea winter 2002 (numbers in millions).

| Length cm | Age (year-class) |  |  |  |  |  |  |  |  |  | Sum |

1) Indices raised to also represent the Russian EEZ.

### 6.2 Swept area estimation

Figs. 6.1-6.4 show the geographic distribution of bottom trawl catch rates (number of fish per 3 naut.mile, corresponding to 1 hours towing) for cod for each of the size groups $<20 \mathrm{~cm}, 20-34$ $\mathrm{cm}, 35-49 \mathrm{~cm}$ and $>50 \mathrm{~cm}$. As in previous years the greatest concentrations of the smallest cod ( $<20 \mathrm{~cm}$ ) were found in the eastern part of the survey area within the Russian EEZ. Also the size groups $20-34 \mathrm{~cm}$ and $35-49 \mathrm{~cm}$ show highest densities in this eastern area. For cod larger than 50 cm the areas with catch rates above 100 per hour have increased slightly compared to the results from the 2001 survey. This is most pronounced in the eastern areas.

Table 6.4 presents the abundance indices by 5 cm length groups for each main area. Standard error and coefficient of variation (CV) are also given. The CV is lowest (7-9\%) in the size range $30-79 \mathrm{~cm}$ and is below $17 \%$ for all size groups above 20 cm . Age-length distribution of the total swept area index as well as the distribution of the index by main area and age is given in tables 6.5 and 6.6 , respectively. For age 4 and older the total indices are similar to the acoustic
observations (Table 6.3), while for ages 1-3 the swept area indices are higher than the acoustic indices.

The time series (1981-2002) is shown in table 6.7. The indices for 1997 and 1998 are adjusted the same way as the acoustic indices to also represent the Russian EEZ. The 2002 results for ages 1 and 3 are the lowest observed since the survey area was extended in 1993. The result for age 2 and ages 4-7 are reasonably close to (77-109\%) the 1993-2001 average.

### 6.3 Growth

Table 6.8 and 6.10 show length and weight by age for each main area. In most years the largest fish at age has been observed in the south-western main areas (A, B and C). This pattern has been less evident in the two latest surveys. For age 8 there are few observations in some main area $D^{\prime}$ and $E$, and those mean lengths and weights are therefore more uncertain.

Tables 6.9 and 6.11 present the time series for mean length (1978-2002) and mean weight (19832002) at age for the entire investigated area. Weights at age were fairly low in the period 19952000, but increased somewhat in 2001. Mean length and weight for ages 2 and 3 showed a considerable increase from 2000 to 2001 and some decrease from 2001 to 2002. For these ages the 2002 weights are about $30 \%$ below the 1983-2001 average. For older fish the 2002 weights are about $10 \%$ below the 1983-2001 average. The annual weight increments observed over the last year are above those observed for the period 1994-2000, but still below those observed in the period 1990-1993 (Table 6.12).

Table 6.8. COD. Length $(\mathrm{cm})$ at age in main areas of the Barents Sea winter 2002.

| Area | Age (year-class) |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

### 6.4 Considerations and conclusion

When using the abundance indices for stock assessment it is important to be aware of all the technical changes introduced during the time series. Better acoustic equipment after 1990 has increased the quality of the indices for all age groups. The survey area was enlarged in 1993. This led to higher indices, especially for the youngest age groups, and the indices also became more accurate all over. The introduction of more fine meshed cod-ends in 1994 and fish length dependent fishing width of the trawl (the time series is adjusted for this) did also lead to more small fish relative to larger fish.

Table 6.13 gives the time series of survey based mortalities (log ratios between survey indices of the same year class in two successive years) since 1993. These mortalities are influenced both by natural and fishing mortality, as well as the true catchability at age for the survey. In the period 1993-1999 there was an increasing trend in the survey mortalities. The trend appears most consistent for the age groups 3-7 in the swept area estimates. The two latest surveys indicate that since 1999 the mortalities have decreased, at least for ages 1-4. Presumably the mortality of the youngest age groups (ages 1-3) is mainly caused by predation, while for the older age groups it is mainly caused by the fishery. Before 2001 the survey mortalities for age 4 and older were well above the mortalites estimated in the ICES assessment. Decreasing survey catchability at increasing age could be one reason for this. Another possible reason could be that the assessment does not include all sources of mortality, like discards, unreported catches, or poorly quantified predation. The 2002 survey indicates some reduced mortality also for ages 5 and 6 .

The observed mortality rates in the acoustic investigations have been more variable. This is explained by changes in fish behaviour and how available the fish is for acoustic registration. During the winter survey 1998 the relative abundance of cod in the bottom channel was lower than the years before, and hence the fish were more available for acoustic registration. This led to lower mortality rates of all year classes from 1997 to 1998 in the acoustic series compared with the swept area series. A similar situation is observed in 2000 compared with 1999.

Table 6.13. Total mortality observed for cod during the winter survey in the Barents Sea in 1993-2001.

| Year | Age |  |  |  |  |  |  |  |

## 7. DISTRIBUTION AND ABUNDANCE OF HADDOCK

### 7.1 Acoustic estimation

As for cod it is expected that the survey best covers the immature part of the stock. At this time of the year a large proportion of the mature haddock (age 6 and older) are on its spawning migration southwestwards out of the investigated area. There are indications that the distribution of age groups 1 and 2 in some years are concentrated in coastal areas not well covered by the survey. This year small haddock was widely distributed, and was found unusually far to the north. This might be caused by rather favourably hydrographic conditions far to the north (Figure 4.2).

Table 7.1 shows the acoustic abundance indices by length and age, and table 7.2 presents the indices by age within the main areas for the pelagic layer and the bottom layer. As in most of the previous years the highest abundance was observed in main area D. The time series (1981-2002), with adjusted indices for 1997 and 1998, is presented in table 7.3. The indices for ages 1, 2 and 3 are well above the 1993-2001 average, while the indices are well below this average for age 6 and older. The indices for ages 4 and 5 are closer to that average (117 and $74 \%$, respectively).

Table 7.1. HADDOCK. Abundance indices at length and age from the acoustic survey in the Barents Sea winter 2001 (numbers in millions).

|  | Age (year-class) |  |  |  |  |  |  |  |  |  | Sum |

1) Indices raised to also represent the Russian EEZ.

### 7.2 Swept area estimation

Figs. 7.1-7.4 show the geographic distribution of bottom trawl catch rates (number of fish per 3 naut.mile, corresponding to 1 hours towing) for haddock for each of the size groups $<20 \mathrm{~cm}$, $20-34 \mathrm{~cm}, 35-49 \mathrm{~cm}$ and $>50 \mathrm{~cm}$. As in 2001, the distribution extends further than usual to the north, especially for the size groups $<20 \mathrm{~cm}$ and $20-34 \mathrm{~cm}$.

Table 7.4 presents the abundance indices by 5 cm length groups for each main area. Standard error and coefficient of variation (CV) are also given. The CVs for haddock are generally higher than those for cod. Within the size range $10-59 \mathrm{~cm}$ the CVs are between 8 and $15 \%$.

Table 7.5 shows the abundance indices by age- and length groups, and table 7.6 presents the indices for each age group by main areas. The time series (1981-2001) is shown in table 7.7. The indices for 1997 and 1998 are adjusted the same way as for cod to also represent the Russian EEZ.

Relative to the 1993-2001 average age 4 appears more abundant and age 5 less abundant in the swept area results compared to the acoustic results (table 7.3).

Figure 7.1. HADDOCK $<20 \mathrm{~cm}$. Distribution in the trawl catches winter 2002 (number per hour trawling).

Figure 7.2. HADDOCK 20-34 cm. Distribution in the trawl catches winter 2002 (number per hour trawling).

Figure 7.3. HADDOCK $35-49 \mathrm{~cm}$. Distribution in the trawl catches winter 2002 (number per hour trawling).

Figure 7.4. HADDOCK $>50 \mathrm{~cm}$. Distribution in the trawl catches winter 2002 (number per hour trawling).

Table 7.4. HADDOCK. Abundance indices (I) at length with standard error of mean (S) from bottom trawl hauls for main areas of the Barents Sea winter 2002 (no. in mill).

${ }^{1)}$ Indices raised to also represent the Russian EEZ.

### 7.3 Growth

Mean length and weight at age for each main area are shown in table 7.8 and 7.10. For some age groups mean length and weight at age are greatest in the east. This was also observed in 2001, but has been rather uncommon in earlier years.

The time series (1983-2002, tables 7.9 and 7.11 ) shows that the slightly increasing trend over the years 1997-2000 has stopped, and for several age groups a decrease was observed in 2001 and 2002.

Table 7.8. HADDOCK. Length (cm) at age in main areas of the Barents Sea winter 2002.

| Area | Age (year-class) |  |  |  |  |  |  |  |

### 7.4 Conclusion

Survey mortalities based on the acoustic indices (tables 7.13) have varied between years, and for most age groups there is no obvious trend. Mortalities based on the swept area indices show a decreasing trend since 1998 (table 7.13).

Concerning the abundance indices it can be concluded that the recruitment to the stock is improving. All the year classes 1998-2001 are above average. The indices for the oldest age groups are, however, rather low. Mean lengths and weights at age are close to previous year's values.

Table 7.13. Total mortality observed for haddock during the winter survey in the Barents Sea for the period 1993-2001.

| Year | Age |  |  |  |  |  |  |  |

## 8. DISTRIBUTION AND ABUNDANCE OF REDFISH

### 8.1 Acoustic estimation

The geographical distribution of echo abundance is shown in figure 8.1 for the golden redfish (Sebastes marinus), and in figure 8.2 for the deep-sea redfish (S. mentella). The maps indicate reduced densities of redfish compared to the combined map for the 2001 survey (Aglen et al. 2002)

Figure 8.1. Sebastes marinus. Distribution of total echo abundance winter 2002. Unit is area back scattering surface $\left(\mathrm{s}_{\mathrm{A}}\right)$ per square nautical mile $\left(\mathrm{m}^{2} / \mathrm{n}\right.$. $\left.\mathrm{mile}^{2}\right)$.

Table 8.1 shows the acoustic indices for $\boldsymbol{S}$. marinus by length-groups and main areas. $91 \%$ of the fish were recorded in area ABCD. In the time series (table 8.2), the indices for 1997 and 1998 are adjusted based on data from 1996 and 1999 to take account of the Russian EEZ. In recent years it has been observed few S. marinus in the eastern Barents Sea, and in 1996 and 1999 the Norwegian EEZ accounted for about $90 \%$ of the total S. marinus acoustic value. The adjustments of the indices for 1997 and 1998 are therefore more precise for $S$. marinus than for cod and haddock. The total index is very low, only $27 \%$ of the 1993-1996 average, and there are no signs of improved recruitment.

Table 8.1. SEBASTES MARINUS. Acoustic abundance indices for main areas of the Barents Sea winter 2002 (numbers in millions).

${ }^{1)}$ Indices raised to also represent the Russian EEZ.

The acoustic index for $\boldsymbol{S}$. mentella by main area (table 8.3) show that main area A and S contributed most to the total value. Main area S represented $48 \%$ of the total estimate and the value is considerably higher compared to two previous years. In 1996 and 1999, $100 \%$ and $96 \%$, respectively, of the total index was registered in the Norwegian EEZ and at Svalbard (S).

Accordingly, only minor adjustments were therefore necessary to take account of the lack of coverage in the Russian EEZ in 1997 and 1998 (table 8.4). For the length groups between 20 and 34 cm the acoustic index is considerably reduced compared to 2001 . The index for $10-14 \mathrm{~cm}$ is the lowest observed.

${ }^{1)}$ Includes unidentified Sebastes specimens, mostly less than 15 cm .
${ }^{2)}$ Indices raised to also represent the the Russian EEZ.

As in previous years, most of the $\boldsymbol{S}$. viviparus are recorded in main areas A and B (table 8.5). The survey covers only the northern margin of this species' geographical distribution. Large variation in the indices from year to year is therefore likely due to variable area coverage in the south western part of the survey area and due to a very patchy distribution. The total index in 2002 is the lowest observed since 1989 (table 8.6).

### 8.2 Swept area estimation

The swept area time series for redfish (tables 8.9, 8.10 and 8.12) are based on catch data from trawls with bobbins gear until 1988 inclusive, and rockhopper gear since 1989. The time series has not been adjusted for this change.

Fig. 8.3 shows the horizontal distribution of $\boldsymbol{S}$. marinus during the swept area investigation. The distribution is very similar to 2001. Table 8.7 presents indices by 5 cm length groups with standard error for each main area in addition to the coefficient of variation for the total area.

Figure 8.2. Sebastes mentella. Distribution of total echo abundance winter 2002. Unit is area back scattering surface $\left(\mathrm{s}_{\mathrm{A}}\right)$ per square nautical $\left(\mathrm{m}^{2} /\right.$ n.mile $\left.{ }^{2}\right)$.

The time series for 1986-2001 (table 8.9), with adjusted indices for 1997 and 1998, shows historic low indices for most of the length-groups, and the lowest total index ever observed. There are no signs of improved recruitment.

1) Indices raised to also represent the Russian EEZ.

The mapping of the distribution of $\boldsymbol{S}$. mentella is not complete in the north western part of the surveyed area due to this species' extensive distribution further north in the Svalbard area, west and north of Spitsbergen. The 2002 coverage was nevertheless more complete than before (fig. 8.4).

Figure 8.4. Sebastes mentella SEBASTES MENTELLA. Distribution in the trawl catches winter 2002 (no. per hour trawling).

Table 8.8 presents the swept area indices by 5 cm length groups with corresponding standard errors for each main area in addition to the coefficient of variation for the total area.

The time series for 1986-2001, with adjusted indices for 1997 and 1998, is presented in table 8.10 .

Similar to the acoustic abundance indices, the swept area indices for $S$. mentella in 2001 show for most size groups a decrease compared to last year. The indices for fish below 25 cm are among the lowest observed. The index for $S$. mentella below 15 cm is less than $10 \%$ (!) of the 1993-1999 average. The future of the $S$. mentella stock is relying on the survival of the last good year classes born in 1989-1990 before the recruitment collapse in 1991. These year classes, at present about 30 cm , compose the bulk of the stock, and should be protected as much as possible if we want to improve the recruitment to maintain a fishery on this resource in the future.

Figure 8.3. Sebastes marinus. Distribution in the trawl catches winter 2002 (no. per hour trawling).

Table 8.10. SEBASTES MENTELLA. ${ }^{1}$ Abundance indices from bottom trawl surveys in the Barents Sea winter 1986-2002 (numbers in millions). 1986-1992 includes only main areas A. B. C and D.

## 9. DISTRIBUTION AND ABUNDANCE OF OTHER SPECIES

### 9.1 Greenland halibut

Fig. 9.1 shows the horizontal distribution of Greenland halibut in the swept area investigations. Important parts of this species' distribution, e.g., northern part of Svalbard and the continental slope, are not covered by the survey. The observed distribution pattern was similar to those observed in previous years' surveys, i.e., mainly in the Bear Island channel towards the Hopen Deep.

Table 9.1 presents the swept area indices by 5 cm length groups with corresponding standard errors for each main area in addition to the coefficient of variation for the total area. Most of the Greenland halibut was found in the northern main areas (D, E and S). For most length groups the coefficient of variation is higher than for cod and haddock. For each of the length groups between 40 and 64 cm the CVs are below $18 \%$.

The time series for 1990-2002, with indices adjusted for 1997 and 1998, is presented in table 9.2. Compared to the 2001 values the indices for fish less than 45 cm are lower, while for fish larger than 45 cm the indices are at or above the 2001 values.

Figure 9.1. GREENLAND HALIBUT. Distribution in the trawl catches winter 2002 (no. per hour trawling).

### 9.2 Blue whiting

Since 2000 the blue whiting has shown a wider distribution than usual, and the echo recordings in 2001 and 2002 also indicated unusual high abundance in the Barents sea. Figure 9.2 shows the geographical distribution of the bottom trawl catch rates of blue whiting in 2002. Compared to the 2001 results, the distribution of catch rates in 2002 extended slightly further to the east and north, while the areas with highest catch rates have decreased. Since the fish was mainly found pelagic the bottom trawl do not reflect the real density distribution, but gives some indication of the distribution limits. Acoustic observations would better reflect the relative density distribution. Figure 9.3 shows the geographical distribution of acoustic values allocated to blue whiting in 2002. The general pattern is similar to the distribution of catch rates, but the densest concentrations are shifted somewhat to the north in the acoustic observations.

The catches of blue whiting was dominated by small fish ( $15-20 \mathrm{~cm}$ in $2001,15-25 \mathrm{~cm}$ in 2002), mainly the 2000 year class.

Figure 9.2. BLUE WHITING. Distribution in the trawl catches winter 2002 (no. per hour trawling).

Figure 9.3. BLUE WHITING. Distribution of total echo abundance winter 2002. Unit is area back scattering surface ( $\mathrm{s}_{\mathrm{A}}$ ) per square nautical $\left(\mathrm{m}^{2} / \mathrm{n}\right.$. mile $\left.^{2}\right)$.

## 10. COMPARISONS BETWEEN RESEARCH VESSELS

In most of the Russian economic Zone the vessels "Persey3" and "Johan Hjort" worked parallel transects 16 n . miles apart, using the same gear and similar sampling procedures. Tables 10.1 (cod) and 10.2 (haddock) compares the age distribution within 5 cm length groups for the fish sampled and aged onboard each vessel. Within the size range $20-34.9 \mathrm{~cm}$, both for cod and haddock, there is a tendency that the Norwegian team observed a lower percentage at age 3, with corresponding higher percentage for age 2 (in the lower part of that size range) and age 4 (in the higher part). This should be further examined through the ongoing PINRO/IMR otolith exchange programme. In the other size groups there were no indications of any discrepancy. At lengths above 50 cm too few fishes are sampled to detect moderate discrepancies.

Table 10.1. Cod, winter survey 2002. Comparison of age distribution (\%) whithin 5 cm length groups, sampled onboard Persey 3 and (P3) Johan Hjort (JH)

It should be noticed that these tables are worked out by running the survey programme with Norwegian and Russian data separately. This means that each aged fish have been given weight according to the swept area estimate for that particular length group for that particular strata. This should be kept in mind when interpreting the results.
