## SURVEY REPORT

# FROM THE JOINT NORWEGIAN/RUSSIAN ECOSYSTEM SURVEY IN THE BARENTS SEA 

AUGUST - OCTOBER 2005

## Volume 1

## Preface

The third joint ecosystem survey was carried out during the period $1^{\text {st }}$ of August to $5^{\text {th }}$ of October 2005. This survey encompasses various surveys that previously have been carried out jointly or at national basis. Joint investigations include the 0 -group survey, the acoustic survey for pelagic fish (previously known as the capelin survey), and the investigations on young Greenland Halibut north and east of Spitsbergen. Oceanographic investigations have always formed a part of these surveys, and studies on plankton have been included for many years. In recent years, observations of sea mammals, seabirds, bottom fishes, and benthos have been included. Consequently, from 2003, these surveys were called "ecosystem surveys".

The present report from the survey will cover many but not all the aspects of the survey. Main focus is on the hydrographical conditions of the Barents Sea, the results from the 0 -group investigations and from the acoustic investigation on pelagic fish (capelin, young herring, blue whiting and polar cod). Preliminary materials on sea mammals and seabird observations are also presented in volume 1 of the report. Results from the investigations on plankton, bottom fishes and benthos will not be fully covered in this volume of the report since the data has not been fully analyzed yet. The complete results from these investigations will be presented in volume 2 of the survey report. The $1^{\text {st }}$ volume of the report was made during a meeting between scientists participating in the survey, in Murmansk 10-14 $4^{\text {th }}$ October.

A list of the participating vessels and aircraft with their respective scientific crews is given in Appendix I.

Besides the participants on the vessels, the following specialists took part in in preparing the survey report: K. Drevetnyak (PINRO), I. Trofimov (PINRO), E. Orlova (PINRO), G. Rudneva (PINRO), V. Nesterova (PINRO); J. E. Stiansen(IMR), B. Bogstad (IMR), M. Mauritzen (IMR).

## Synopsis

The main aim of the ecosystem survey was to map the distribution and abundance of the young and adult stages of several demersal and pelagic fish species, and in addition to gather information about hydrographical features, zooplankton, benthos, seabirds and sea mammals.

The water temperature in all observed areas was higher $\left(+0.5-1{ }^{\circ} \mathrm{C}\right)$ than the long term mean but somewhat lower than in the same period 2004.

The 2005 haddock yearclass is very rich. The 2005 yearclass of cod, herring, capelin and is near the average level. 0 -group of the western component of polar cod is below the average level. 0-group of Greenland halibut, redfish, saithe and the eastern component of polar cod were estimated to be poor.

The total capelin stock was estimated to be 0.3 million tonnes, which is $50 \%$ lesser than last years estimate. About 0.17 million tonnes were assumed to be maturing.

The polar cod stock was estimated to be 1.8 million tonnes, which is 0.7 million tonnes higher then last year.

Juvenile Norwegian spring spawning herring was estimated in the southern part of the Barents Sea to be 2.8 million tonnes.

Blue whiting of age groups 1 to 9 were observed in the western and southwestern parts of the surveyed area, and the biomass of this stock component was estimated to be 1.1 million tonnes.
SYNOPSIS ..... 2

## 1 Methods

### 1.1 Hydrography

The hydrographical investigations consisted of measurements of temperature and salinity in depth profiles along sections and distributed over the total investigated area. All vessels used CTD-zondes. For the first time it was agreed to carry out Norwegian and Russian oceanographic section by the vessels operating in the same area. Russian vessel sampled Norwegian sections in REEZ, but unfortunately the Russian Bear island-west section was not sampled by R/V "Johan Hjort". This cooperation should be improved and continue in future.

### 1.2 0-group fish investigations

The geographical distribution of 0 -group fishes was estimated with a small mesh mid-water trawl ("Harstadtrål"). All vessels, which participated in the survey in 2005, used this type of mid-water trawl which was first recommended in 1980 (Anon. 1983). The standard procedure consisted of tows at 3 depths, each of 0.5 nautical miles, with the headline of the trawl located at 0,20 and 40 m . Additional tows at 60 and 80 m , also of 0.5 nm distance, were made when the 0 -group fish layer was recorded deeper than 60 m or 80 m on the echo-sounder. Trawling procedure was standardised in accordance with the recommendations made in 1980. A smaller sized pelagic trawl was used during the first 20 years of the 0 -group investigations. After 1985 the present gear has been used regularly. In the mid 1990s, Nakken and Raknes (1996) recalculated the indices from the first 20 years. Their new indices are based upon an estimate of how many 0 - group cod and haddock that would have been caught if the new equipment had been used during the whole period from 1965. The indices of cod and haddock recalculated by Nakken and Raknes (1996) have been incorporated in the 0 -group reports since 2001. Prozorkevich (2001) calculated abundance indices for 0 -group herring since 1993. The new type of 0 -group indices was presented for the first time in volume 2 of last years report and are revised and presented in this report. These indices, which are given both with and without correction for catching efficiency, are calculated by the method of stratified sample mean. This new method allows for confidence limits to be calculated, and makes better use of the total data than the indices used hitherto have made. When the new method has been carefully scrutinized and compared to previous methods, the new indices are meant to replace the Area Index after a short period of overlap between the two methods. The Logarithmic Index is discontinued from this year.

Most of the stations this year were taken 32-35 nautical miles apart. Area based abundance indices (ABI) were estimated by using the computer program Map Viewer. Mean values of abundance indices were calculated both for the period 1985-2005 and for the whole period 1965-2005.

### 1.2.1 Stratified sample mean estimator

The number of fish per $\mathrm{nm}^{2}, \rho_{s, l}$, at length, $l$, at each station, $s$, are estimated by the following equation

$$
\rho_{s, l}=\frac{f_{s, l} \cdot \operatorname{Keff}}{a_{s}}
$$

where $f_{s, l}$ is the calculated frequency of length $l$ at station $s$, Keff is the correction functions defined below, and $a_{s}$ is the swept area found by

$$
a_{s}=\frac{d_{s} \cdot w s}{1852}
$$

where $w s$ is the wingspread of the trawl and is set to 20 m and $d_{s}$ is the effective trawl distance found as trawl total distance divided on the number of depth steps.

The stratified swept area estimate, is given by

$$
\bar{y}_{s t}=\sum_{i=1}^{L} A_{i} \bar{y}_{i}
$$

where $L$ is the number of strata, $A_{i}$ is the covered area in the $i$-th stratum, and $\bar{y}_{i}$ is the average density in stratum $i$. The estimated variance of the stratified mean $\bar{y}_{s t}$ is

$$
\operatorname{var}\left(\bar{y}_{s t}\right)=\sum_{i=1}^{L} A_{i}^{2} \frac{s_{i}^{2}}{n_{i}}
$$

where

$$
s_{i}^{2}=\frac{\sum_{s=1}^{n_{i}}\left(y_{i, s}-\bar{y}_{i}\right)^{2}}{n_{i}-1}
$$

The standard error of $\bar{y}_{s t}$ is given by

$$
\operatorname{se}\left(\bar{y}_{s t}\right)=\sqrt{\operatorname{var}\left(\bar{y}_{s t}\right)}
$$

and the confidence limits $C L$ are found by

$$
C L=\bar{y}_{s t} \pm 1.96 \cdot \operatorname{se}\left(\bar{y}_{s t}\right)
$$

The area is stratified by 22 strata (Fig. 2.5). To find the coverage of a stratum, the station positions are loaded into GIS software. A buffer zone of 20 nm is added to the border of the outer trawl points. The conic projection Albers equal-area, with center latitude at $75^{\circ} \mathrm{N}$, center longitude at $30^{\circ} \mathrm{E}$, and standard latitudes at $70^{\circ}$ and $80^{\circ} \mathrm{N}$, is used for area estimation.

The sampling trawl is highly selective for 0 -group fish according to its species and length. It is possible to estimate the special correction function Keff for trawl capture efficiency by regressions on fish densities received during trawling and acoustic registrations of relatively "pure" concentrations. Correction functions for three species types are:

$$
\begin{aligned}
\text { Keff }_{\text {gadoids }} & =17.065 * \exp (-0.1932 * l) \\
\text { Keff }_{\text {capelin }} & =7.2075 * \exp \left(-0.1688^{*} l\right) \\
\text { Keff }_{\text {herring }} & =357.23 * \exp (-0.6007 * l)
\end{aligned}
$$

where $l$ is the length in cm . These correction functions can be applied directly to the observed length frequencies at each station. But since the functions above give unreasonably high numbers as $l$ decreases, it was decided to set for $l<4 \mathrm{~cm}$ Keff gadoids constant to 8 , Keff herring constant to 30 and Keff capelin constant to 4 . There is currently no correction function for other fish species.

### 1.3 Acoustic survey for pelagic fish

A team consisting of N.G. Ushakov (PINRO) together with S. Aanes, E. Olsen and then H. Gjøsæter (IMR) on board "G.O. Sars" conducted a joint leadership over the investigations, undertaking a day-to-day planning of survey grid.

Data on cruise tracks, hydrography, trawl catches, integrator values etc. were exchanged by use of e-mail, and these data were used during the day-to-day planning of the survey.

The survey area was chosen based on general knowledge of the distribution of the target species, and on information about fish distribution from the first parts of the ecosystem survey.

The main area of capelin distribution were surveyed with course lines $32-35$ nautical miles apart. In area of maximal capelin densities there were made extra tracks with course lines 15 nautical miles apart. All regions of the Barents Sea and adjacent areas of the Norwegian Sea were covered.

All participant vessels used ER-60 echo sounders (with ER-60 software, version 2.1.1). The Norwegian vessels had BEI, while the Russian vessels used FAMAS and BI-60 postprocessing system. Also "G.O. Sars", "J. Hjort" and "Jan Mayen" was equipped with transducers on adjustable keels that can be lowered in rough weather to avoid the damping effect of bubbles. Echo intensities per nautical mile were integrated continuously, and mean values per 5 nautical miles were recorded for mapping and further calculations. The echograms, with their corresponding $\mathrm{s}_{\mathrm{A}}$-values, were scrutinised every day. Contributions from the seabed, false echoes, and noise were deleted.

The corrected values for integrated echo intensity were allocated to species according to the trace pattern of the echograms and the composition of the trawl catches. Data from pelagic trawl hauls and bottom trawl hauls considered representative for the pelagic component of the stocks, which is measured acoustically, were included in the stock abundance calculations.

The echo sounders were watched continuously, and trawling was carried out whenever the recordings changed their characteristics and/or the need for biological data made it necessary. Trawling was thus carried out both for identification purposes and to obtain biological observations, i.e., length, weight, maturity stage, stomach data, and age.

In total, the Norwegian vessels carried out 706 trawl hauls and the Russian vessels carried out 402 trawl hauls, so in total 1108 hauls were made during the survey (while 1000 hauls were made in 2004). The vessels gave the $\mathrm{s}_{\mathrm{A}}$-values in absolute terms based on sphere calibrations, that is, as scattering cross section in $\mathrm{m}^{2}$ per square nautical mile. The acoustic equipment of the vessels was calibrated by standard spheres (see Appendix II).

### 1.3.1 Area coverage

The weather conditions were favourable during most parts of the survey, and consequently, an almost total coverage of the Barents Sea by a dense survey grid was achieved. In 2005 the
survey was started from the south. "Smolensk" and "F. Nansen" surveyed the eastern, northeastern areas, central part of the Barents Sea and shallow areas to the south and north-east of Spitsbergen. "G.O. Sars" and "Johan Hjort" surveyed the western, north-western and central parts while "Jan Mayen" observed northern, north-western and north-eastern areas of Spitsbergen. Altogether, total survey carried out 208 vessel/days that is one week less than in 2004.

### 1.3.2 Computations of the stock sizes

The computations of number of individuals and biomass per length-and age group of the pelagic fish stocks were made using the stock size estimation program "BEAM" built on SAS GIS and developed at IMR. A strata system, dividing the Barents Sea in squares of $1^{\circ}$ (latitude) $\times 2^{\circ}$ (longitude), was used as basis for the calculation.

The mean $s_{A}$-value in each basic square was converted to fish area density $p_{\mathrm{A}}$ using the relation

and number of fish was found by multiplying with the area of the square. Numbers were converted to biomass by multiplying with observed mean fish weight in each length group.

The target strength relation for capelin is given by:

corresponding to a $\sigma$-value of $5.00 \cdot 10^{-7} \cdot L^{1.91}$

The target strength relation for polar cod and blue whiting is given by:

$$
\mathrm{TS}=10 \cdot \log \left(\frac{\sigma}{4 \pi}\right)=21.8 \cdot \log \mathrm{~L}-72.7
$$

corresponding to a $\sigma$-value of $6.7 \cdot 10^{-7} \cdot L^{2.18}$
The target strength relation for herring is given by:

$$
\mathrm{TS}=10 \cdot \log \left(\frac{\sigma}{4 \pi}\right)=20.0 \cdot \log \mathrm{~L}-71.9
$$

corresponding to a $\sigma$-value of $8.1 \cdot 10^{-7} \cdot L^{2.00}$

### 1.4 Bottom trawl survey

The number and biomass of fish per length group were calculated from bottom trawl catches using the "swept-area" method with a strata system developed at IMR. Number at age of cod, haddock and Greenland halibut will be presented in Vol. II of the report.

Acoustic registrations of bottom fish were carried out along all cruise tracks, with division of $\mathrm{s}_{\mathrm{A}}$-values by species based on trawl catches data.

### 1.4.1 Swept area analysis of bottom fishes

Length based indices for each sub-area was estimated using the method of (Jakobsen et al. 1997). For each trawl station and length, fish density was estimated by:

$$
P_{s, l}=\frac{f_{s, l}}{a_{s, l}},
$$

where:
$P_{s, l}$ is the number of fish/n.m. ${ }^{2}$ observed at station $s$ (length $l$ )
$f_{s, l} \quad$ is the estimated frequency of length $l$
$a_{s, l}$ is swept area given by

$$
a_{s, l}=\frac{d_{s} * E W_{l}}{1852}
$$

$d_{s}$ is towed distance (n.m.) and $E W_{l}$ is the length dependent effective swept width.

For Greenland halibut, redfish, long rough dab and the wolffishes, there is no available estimate of the length dependent effective swept width, so it was set to 25 m , independent of fish length and trawl depth.

Based on (Dickson 1993a; Dickson 1993b), length dependent effective fishing width for cod and haddock was included in the calculations where EW was:

$$
\begin{aligned}
& E W_{l}=\alpha * l^{\beta} \quad \text { for } \quad l_{\min }<l<l_{\max } \\
& E W_{l}=E W_{l_{\min }}=\alpha * l_{\min }^{\beta} \quad \text { for } \quad l \leq l_{\min } \\
& E W_{l}=E W_{l_{\max }}=\alpha * l_{\max }^{\beta} \quad \text { for } \quad l \geq l_{\max }
\end{aligned}
$$

The parameters used for cod and haddock are given in the following table:

| Species | $\alpha$ | $\beta$ | $\boldsymbol{l}_{\min }$ | $\boldsymbol{l}_{\max }$ |
| :--- | :--- | :--- | :--- | :--- |
| Cod | 5.91 | 0.43 | 15 cm | 62 cm |
| Haddock | 2.08 | 0.75 | 15 cm | 48 cm |

Point observations for fish density based on length $(l)$ was summed up in 5 cm length groups denoted by $p_{s, l}$. Stratified abundance indices for each length group and strata were generated using

$$
L_{p, l}=\frac{A_{p}}{S_{p}} * \sum P_{s, l}
$$

where:
$L_{p, l}$ is the index for stratum $p$, length group $l$

$$
A_{p} \text { area (n.m. }{ }^{2} \text { ) of stratum } p
$$

$S_{p}$ is the number of stations in stratum $p$

For each subarea, the total number of fish in each 5 cm length group was estimated by summing over all strata in the sub area, and the total number of fish in each age group in the area was estimated using an age/length key. Finally, the total index for each length and age class is the sum of the values for all sub areas.

For each year, an age/length key was estimated for each stratum. All age samples for a stratum were used. Age samples from a length group was weighted by the index of the number of fish in the 5 cm length group within a stratum divided by the number of age samples in the length group:

$$
w_{p, l}=\frac{L_{p, l}}{n_{p, l}},
$$

where $n_{p, l}$ is the number of age samples in stratum $p$ and length group $l$.

The proportion of age $a$ at length $l$ was estimated using

$$
P_{a}^{(l)}=\frac{\sum_{p} n_{p, a, l} * w_{p, l}}{\sum_{p} n_{p, l} * w_{p, l}}
$$

where $P_{a}^{(l)}$ is the weighted proportion of age $a$ in length group $l$ in stratum $p$,
and $n_{p, a, l}$ is the number of age samples of age $a$ in length group $l$.

The sum of the weighted factors in a sub area is the abundance index for the total number of fish in the sub area. The number of fish at age was estimated by:

$$
N_{a}=\sum_{p} \sum_{l} L_{p, l} * P_{a}^{(l)}
$$

Average length and weight at age was estimated using (only shown for weight):

$$
W_{a}=\frac{\sum_{p} \sum_{l} \sum_{j} W_{p, a, l, j *} w_{p, l}}{\sum_{p} \sum_{l} \sum_{j} w_{p, l}},
$$

where $W_{p, a, l, j}$ is the weight for sample $j$ in length group $l$ in stratum $p$ and age $a$.

### 1.4.2 Strata system used

A new strata system was constructed in 2004 covering the whole Barents Sea to include the total survey area. The new geographic system is also depth stratified using GEBCO depth data. Since this is the second total coverage of bottom fishes, it is not possible to compare the indices to corresponding indices in years before 2004. However, for the species cod, haddock and Greenland halibut, there are indices from approximately the same period in earlier years, at least for some regions of the Barents Sea. These indices will be presented in Vol. II of the report together with the age-based indices for 2005.

### 1.5 Plankton investigations

Data on phytoplankton abundance was obtained in several ways during the joint RussianNorwegian Survey. On the Norwegian vessels G.O. Sars and Johan Hjort samples for chlorophyll $\boldsymbol{a}$ were obtained at nearly all CTD stations through filtration of water from water bottles at discrete depths from $0-100 \mathrm{~m}$, the number of samples varying slightly depending on bottom depth at the specific localities. Phytoplankton was filtered using GFC filters, and samples were frozen for later analysis of chl a content at the IMR laboratory. For both vessels mentioned above phytoplankton nutrient samples were obtained from the same water bottles on most CTD stations, at depths from the surface to the bottom according to a predefined scheme as determined for the Ecosystem cruise and specific bottom depth of each station. On G.O. Sars a fluorometer was used as an additional instrument, connected to the CTD, logging chl $\boldsymbol{a}$ fluorescence as a continuous vertical profile along with temperature and salinity for all CTD stations. These data must however be calibrated with the help of chl $\boldsymbol{a}$ determined from the water bottle samples obtained at the same stations.

For the first time this year, samples for phytoplankton species composition and abundance have been obtained from the Norwegian vessels G.O. Sars and Johan Hjort. For every second or third station additional quantitative water samples were obtained from the water bottles at $5,10,20$ and 30 m depth. Immediate upon retrieval of the seawater rosette sampler, two 20 ml phytoplankton samples were taken from each bottle at the above mentioned depths. The samples from the two series were kept separate as they were pooled in two dark lightprotected 100 ml flasks. The first series was fixated by adding 2 ml lugol, while the second series was fixated using $2.5 \mathrm{ml} 20 \%$ formaldehyde. Slightly less frequent a $10 \mu \mathrm{~m}$ meshed phytoplankton net with a $0.1 \mathrm{~m}^{2}$ opening was vertically operated from $0-30 \mathrm{~m}$ to obtain a qualitative phytoplankton sample. If the net itself showed no greenish colour (sign of phytoplankton) after retrieval, it was re-deployed once or twice to obtain a sufficient amount of phytoplankton to trace less abundant, but potentially important species. After gentle mixing of the water from the net cod-end two dark light-protected 100 ml flasks were filled, each with approximately 80 ml seawater, then adding 2 ml lugol and $4 \mathrm{ml} 20 \%$ formaldehyde for fixation respectively.

On board the Russian vessels information on phytoplankton abundance was obtained through a semi-quantitative approach. The phytoplankton conditions were analyzed from the zooplankton samples by visual estimation of micro-algae concentration and frequency of cell occurrence using a 5-unit scale - single (1) to mass (5) occurrence. Phytoplankton composition was determined to genus.

Zooplankton sampling on the Norwegian vessels was carried out by WP-2 plankton nets with a $0.25 \mathrm{~m}^{2}$ opening and $180 \mu \mathrm{~m}$ mesh size. Usually two hauls were made at each station, one
was taken from the bottom to the surface and the other one from 100 m to the surface. Additional stratified sampling was carried out daily by the Mocness multinet planktonsampler. During the last part of the Norwegian vessel RV G.O. Sars survey, a Russian Juday net having a $0.106 \mathrm{~m}^{2}$ opening area was also used along with WP2 net as part of a sampling comparison exercise.

The sampling on the Russian vessels was carried out by Juday-nets with $0.1 \mathrm{~m}^{2}$ opening and $180 \mu \mathrm{~m}$ mesh size in depth intervals, bottom-100m, 100-50m and $50-0 \mathrm{~m}$. Additional sampling was carried out by WP-2 on "F. Nansen".

On board the Norwegian vessels samples were normally split in two, one part was fixated in 4\% borax neutralized formalin for species analysis and the other one was size-fractioned as follows; $>2000 \mu \mathrm{~m}, 2000-1000 \mu \mathrm{~m}$ and $1000-180 \mu \mathrm{~m}$ size categories. These size-fractionated samples were weighed after drying at $60^{\circ} \mathrm{C}$ for 24 hours. Large organisms like medusa, krill, shrimp, fish and fish larvae were counted and their length or size measured separately before drying and weighing.

Zooplankton samples collected onboard the Russian vessels at the stations where both WP-2 and Juday net was taken were size-fractionated and dried as on the Norwegian vessels. Otherwise, the processing of Juday net samples from the Russian vessels included preliminary species identification and abundance determination, including wet weight determination of biomass from each haul. A more detailed processing of species and stage composition as well as numerical abundance will be undertaken in the laboratory according to standard procedures. Dry weights will be derived using a conversion factor of 0.2 . All zooplankton data will be presented as biomass or numbers per $1 \mathrm{~m}^{2}$ surface.

In 2005 it was the intention from the research vessel G.O. Sars to conduct a restricted experiment on acoustic classification and categorization of zooplankton using a Linux implementation of the Bergen Echo Integrator system (BEI). The aim was to sample selected echo registrations by a variety of sampling gear, including a newly developed macro-plankton trawl with the Multisampler mounted, Mocness, WP2 and pelagic trawl and compare catches from these various gears with independent categorization derived by the BEI system. However, due to an incomplete implementation of specific modules of the Linux BEI system, this exercise could not be undertaken as planned. The macro-plankton trawl was however, used on three occasions with the Multisampler mounted to verify acoustic registrations in various parts of the water column.

Final plankton results will be presented in $2^{\text {nd }}$ volume of the survey report.

### 1.6 Stomach investigations

According to agreement at the Russian-Norwegian meeting in March 2005 capelin stomachs were collected at the Norwegian (G.O. Sars) and Russian vessels (Smolensk and F. Nansen) in August-September 2005. Near 400 capelin stomachs were collected by Norwegian and Russian vessels. The samples were collected and treated as was discussed at the Meeting in April 2005. All samples were fixated in 4\% formalin until later analysis in the laboratory at PINRO. Stomachs will be processed by PINRO zooplankton specialists according to standard procedures. The results will be presented in March 2006.

Stomach samples of blue whiting were sampled on the Norwegian vessels. At each station one stomach pr. 5 cm length category was sampled and frozen for later analysis at the IMR lab.

Also stomach samples of cod were taken according to standard protocol on all participating vessels.

### 1.7 Sea mammals and birds investigations

Marine mammals and bird observations (species and numbers observed) were registered onboard R/V "G.O. Sars", "J. Hjort", from Norwegian side, and "F. Nansen", "Smolensk", from Russian side.

Onboard Norwegian R/Vs observations were made by three observers (one sea bird and two marine mammal observers) simultaneously from vessel bridges, the marine mammal observers covering a $180^{\circ}$ sector ( $90^{\circ}$ each) and the sea bird observer covering one $90^{\circ}$ sector. The ship-following sea bird species, such as gulls and northern fulmars, were counted every half hour.

Onboard Russian R/Vs, observations of marine mammals and sea birds were carried out onboard "F. Nansen" and of marine mammals only onboard "Smolensk". Observations onboard both vessels were carried out by one observer from the vessel top point about 12-15 m above sea surface covering $360^{\circ}$.

Observer activity was limited by weather conditions. When the weather conditions were not sufficient for good quality observations (wave height more than 6 on the Beaufort Scale or reduced visibility due to fog or precipitation) observations were not carried out. Observes were active along transects only, and not during station work.

During September 19. - 29. observations of marine mammals and birds (distribution, specified and counted) were carried out onboard Russian research aircraft An-26 "Arktika", as in previous years. Two observers covered both sides of the aircraft sides along swaths equivalent to two flight altitudes. Methods for aerial observations for marine mammals and birds, including requirements for weather conditions, are described in detail in the 2004 Survey Report ( $2^{\text {nd }}$ Volume).

### 1.8 Benthos observations

### 1.8.1 Purpose

The purpose of the benthos investigation was to

1) sample material for description of benthic habitats and communities in the Barents Sea,
2)evaluate different sampling methods, and
3)to continue established time series of benthic community monitoring.

This should lead to criteria for selection of suitable monitoring locations in the Norwegian EEZ and improved procedures for providing results on benthos relevant for an ecosystem approach to management of marine resources in the Barents Sea.

### 1.8.2 Criteria for selection of sampling locations

In general the distribution of locations for benthic sampling was integrated in the survey lines of the different vessels. Bycatch of invertebrates were recorded from all bottom trawl hauls. Criteria for the selection of locations for special benthic sampling varied between the ships and the two institutions. For the Russian part of the Ecosystem survey the locations were already decided from previously established monitoring stations. The main part of the Norwegian benthic survey was carried out with RV GO Sars. The three most important criteria for selection of locations along the survey line were representation of 1) different geographic regions, 2) different topographic structures, and 3) areas with different degrees of fishing intensity. Additionally, in the eastern part of the survey area locations were selected where red king crab previously had been recorded.

A detailed topographic map (based on a compilation of available bathymetry data from Olex) of the Norwegian sector was used to identify topographic structures (sea floor elevations, breaks and trenches, etc), whereas VMS satellite tracking data from the Norwegian Fisheries Directorate was used to identify areas with high fishing activity.

### 1.8.3 Gears and methods

PINRO and IMR had a slightly different approach to the benthic survey due to different history of benthic research. In the Norwegian part of the Barents Sea mapping is essential to evaluate the representativity of results on the benthos. It was decided to use a set of different gears with different sampling characteristics in order to provide a broad picture of the benthos. GO Sars was selected for this purpose since it could operate seabed inspection equipment as well as grab, sled, and trawl.

Table 2.8.1 gives an overview of the different gears used onboard the five research vessels involved in the ecosystem survey.

The following gears were used during the ecosystem cruise:

- Video rig (documents benthic habitats and megafauna),
- Beam trawl and Sigsby trawl (collect animals that live on the seafloor),
- van Veen grab (provides samples to quantify animals that live upon and in the sediments),
- RP-sled (samples organisms that live right above and on the seabed).

The combination of different sampling gear provides a good picture of the sampled habitats and their fauna.

### 1.8.4 Bottom trawl

For most hauls with bottom trawl (Campelen) benthic invertebrate bycatch was processed onboard, but a few samples from GO Sars were preserved or documented photographically for later identification.

Large forms of invertebrates (Asteroidea, Holoturoidea, Ophiuroidea and Porifera) were sorted out from the fish catch on deck onboard F Nansen. Smaller forms were sorted into species and taxonomic groups from the whole or a fraction of the remaining bycatch. The sorted organisms were counted and weighted (wet weight). Onboard GO Sars only Porifera was sorted out on deck. Other benthic invertebrates were sorted out from the whole or a fraction of the total catch.

### 1.8.5 van Veen grab

Quantitative collecting of macro-zoobenthos was carried out with van Veen grabs. The grab used onboard F. Nansen had a standard size covering a seabed area of $0.1 \mathrm{~m}^{2}$, whereas a larger grab (sampling area of $0.25 \mathrm{~m}^{2}$ ) was used onboard GO Sars. Five replicate samples were collected with the small grab, and three replicates with the large. The size of the samples was recorded either as filling degree (F. Nansen) or volume (GO Sars). Type of bottom sediments was examined visually and a small subsample was collected from each grab onboard GO Sars. The samples were sieved in running seawater using a smallest mesh size of 0.5 mm (F Nansen) and 1 mm (GO Sars). Sieved bottom organisms with remains of sediments were fixed in $4 \%$ neutralized solution of formaldehyde. Borax was used as a buffer. Onbord F Nansen, dominating species and forms of macro-zoobenthos were recorded in the observation log during sieving and fixing of the samples.

### 1.8.6 Epibenthos trawls

Qualitative sampling of zoobenthos was carried out with a modified Sigsby trawl (F Nansen) and a small beamtrawl (GO Sars). The Sigsby trawl had a steel frame of $1 \times 0.35 \mathrm{~m}$. The mesh size of the inner cover in the net was 10 mm , with a codend part with 5 mm mesh size knotless netting.

The beamtrawl had an opening of 2 m and a net similar to the Sigsby trawl (inner cover in the net $=10 \mathrm{~mm}$ mesh, codend $=4 \mathrm{~mm}$ mesh size).

Trawling duration was set to 5 or 10 min at a vessel speed of 1,5 knots. The samples were sieved trough 10 and 5 mm (F Nansen) or 5 and 2 mm (GO Sars) sieves. Organisms collected in the Sigsby trawl were sorted out and processed onboard. Dominating invertebrates were counted and length measured. Organisms that required further taxonomic identification were fixed in $75 \%$ ethyl alcohol and $4 \%$ formalin for later examination. The samples from the beamtrawl were fixed on $4 \%$ formalin for sorting and faunistic identification in the laboratory on land.

### 1.8.7 Epibenthic sled (RP-sled)

For a description of the RP-sled (Rothlisberg-Pearcy epibenthic sled) collects epibenthic organisms from the sediment surface to height of about 50 cm above the sedbed. The net $($ mesh size $=0.5 \mathrm{~mm})$ has a cod end similar to large plankton nets. Sampling was performed
with a wire length of $1,5-2$ times water depth with a speed close to 1 knot. The duration of the hauls standardised to 20 min . The sample was carefully washed out from the cod end and net in to a large bucket. The samples were sifted using 0.5 mm as the smallest mesh size. Most of the crustaceans were separated from the sample by repeated procedures of flotation (decantation) of the water trough fine $(0.5 \mathrm{~mm})$ sieve. The remaining sample was fractionated using different sized sieves (e.g. $8 \mathrm{~mm}, 4 \mathrm{~mm}, 2 \mathrm{~mm}, 500 \mathrm{um}$ ) depending on the composition of the sample. The fractions were fixed separately in $4 \%$ formaldehyde.

### 1.8.8 Video survey

Video records were provided onboard GO Sars with IMR's own tethered video camera (TVC). This is a platform consisting of a video-camera with pan and tilt control, two lights, and a metal frame with weights, connected to a cable from the ship. The TVC is deployed while the ship is allowed to slowly drift with the current, and was kept close ( $1-2 \mathrm{~m}$ ) to the seabed for at least 20 minutes. Logs for the deployments included GMT time, geographic positions, depth and general description of the habitat (substrate type and dominating epifauna).

## 2 RESULTS AND DISCUSSION

Survey routes with trawl stations; hydrographical stations, plankton stations and benthos sampling stations are shown in Fig. 2.1, 2.2, 2.3 and 2.4 respectively.

### 2.1 Hydrographical conditions

Figs. 2.1.1-2.1.4 show the temperature and salinity conditions along the oceanographic sections: Kola, Kanin, North Cape-Bear Island and Bear Island-West. The mean temperatures in the main part of these sections are presented in Table 2.1.1. Anomalies have been calculated using the long-term mean for the period 1954-1990. Horizontal distribution of temperature and salinity are shown for depths of $0,50,100,200 \mathrm{~m}$ and near the bottom in Figs. 2.1.5-2.1.14.

In general the temperature was above the long-term mean throughout the Barents Sea. The surface water temperatures were higher than the long-term mean by $0.8-1.3^{\circ} \mathrm{C}$ on average in the whole investigated area. Maximum positive anomalies were observed near Sørkapp and to the west of Cape Kanin. However, in the south-western part of the survey area the temperatures were slightly higher than normal, and in the south-eastern part negative anomalies (on average $-0.5^{\circ} \mathrm{C}$ ) were found. The distribution of the bottom temperature had the same features as at the surface but with smaller anomalies. In the bottom layer, positive anomalies of water temperature were found practically in all the observed areas except in the south-eastern part, where waters with negative temperature anomalies (down to $-1.2^{\circ} \mathrm{C}$ ) were distributed to $46^{\circ} \mathrm{E}$ and $72^{\circ} \mathrm{N}$.

The water salinity in the survey area was in general close to the long-term mean except for saltier surface waters in the south-eastern and northern parts of the Barents Sea, and also near the Kanin Peninsula.

The maximum horizontal temperature gradients $\left(0.20-0.35^{\circ} \mathrm{C}\right.$ per nautical mile) were observed for the Polar Front south-east of Bear Island and west of Sørkapp at 50 m depth.

The Kola section is divided into three parts. The inner part represents the Murmansk Coastal Current and contains mostly coastal water masses, the central part represents the Murmansk Current and usually contains both coastal and Atlantic water masses, and the outer part represents the Central Branch of the North Cape Current and contains mostly Atlantic water masses. In the three parts the temperature anomalies in the $0-50 \mathrm{~m}$ layer were $1.1,0.8$ and $0.7^{\circ} \mathrm{C}$, respectively. In the $0-200 \mathrm{~m}$ layer the corresponding anomalies were $0.9,0.7$ and $0.7^{\circ} \mathrm{C}$. The Kanin section is divided into two parts. The inner part represents the Kanin Current and had positive temperature anomalies of $1.0^{\circ} \mathrm{C}$ in both the $0-50 \mathrm{~m}$ and $0-200 \mathrm{~m}$ layers. The outer part represents the Novaya Zemlya Current and had positive temperature anomalies of $0.6^{\circ} \mathrm{C}$ in the $0-200 \mathrm{~m}$ layer. The North Cape-Bear Island Section represents the North Cape Current, which mostly contains Atlantic water masses. The temperature anomalies in $0-50 \mathrm{~m}$ and $0-200 \mathrm{~m}$ layers were 1.1 and $0.9^{\circ} \mathrm{C}$, respectively. The Bear IslandWest Section is divided into three parts representing the middle, east-marine and east-coastal branches of the Norwegian Current. Temperatures in the $0-50,0-200 \mathrm{~m}$ and $0-500 \mathrm{~m}$ layers were all high. The anomalies in all three parts for all three depth layers ranged between 1.0 and $1.3^{\circ} \mathrm{C}$.

Compared to 2004 the surface temperature generally was lower (on average $0.5-1.5^{\circ} \mathrm{C}$ ), with the highest deviation in the south-western part (more than by $2^{\circ} \mathrm{C}$ lower in 2005). Contrary,
the bottom temperatures were between approx. 0.1 and $1.2^{\circ} \mathrm{C}$ higher in 2005 than in 2004 in most of the Barents Sea.

The high temperature in the Barents Sea is mostly due to the inflow of water masses with high temperatures from the Norwegian Sea. In addition, prevailing southern, southwestern and southeastern wind in the north of the sea during the survey promoted the penetration of the warmer and saltier water masses northward.

### 2.2 Distribution and abundance of $\mathbf{0}$-group fish and Gonatus fabricii.

The distribution of various species of 0 -group fish are shown in Figs 2.2.1-2.2.9. Abundance indices are shown in tables 2.2 .1 to 2.2.3. The density grading is based on catches, measured in number of fish per square nautical mile. More intensive colouring indicates denser concentrations. Length frequency distributions of the main species are given in Table 2.2.4. The coverage of 0 -group fish distributions towards the north was good, but the western borders for some of the 0 -group distributions were not completely allocated.

### 2.2.1 Capelin

Capelin was distributed mainly in the eastern areas, but scattered concentrations were also observed south of Spitsbergen. Dense concentrations were found in a wider area than last year. Total abundance of 0 -group capelin is above 2004, but again below the long-term average level.

### 2.2.2 Cod

0 -group cod had a wide distribution area, but compared to 2004 there was a displacement to the west and north-west. Dense concentrations were found between $12^{\circ}-38^{\circ}$ E. Low densities in the eastern areas were found in patchy distributions only. Abundance of 0 -group cod was on an average level and near the same as in 2004.

### 2.2.3 Haddock

The total distribution of 0 -group haddock was similar to last year, but with higher densities. Dense concentrations of 0 -group haddock were registered in large areas in the western Barents Sea and west of Spitsbergen. Both the area index and the stratified sample mean index shows that haddock, once again, has produced a yearclass at a record high level.

### 2.2.4 Herring

0 -group herring was distributed in scattered concentrations mostly. Dense concentrations were found in a small area in the central Barents Sea and only one catch south-west of Spitsbergen Distribution area in the central Barents Sea and west of Spitsbergen has slightly decreased compared to last year. Only patchy distributions were observed to the east and along the coast. Abundance of herring 0 -group is much lower than in 2004 and slightly below the average level for the period 1980-2005.

### 2.2.5 Polar cod

The eastern component has near the same distribution as in 2004 but at lower densities. The distribution of 0 -group polar cod seems to extend even further north than the covered survey area. However, abundance of eastern polar cod seems to be poor.

Western component of 0 -group polar cod had near the same distribution west of Spitsbergen as last year, with a small area of dense concentration. South and east of Spitsbergen, both scattered and dense concentrations were found in a wider area. Results from the two methods differ regarding to the long term mean, but the abundance of the western component of polar cod was stronger than in 2004.

### 2.2.6 Saithe

Total distribution area of 0-group saithe was drastically decreased compared to the last year. Saithe was found in the central area in scattered concentrations only. The yearclass is below the long term average and can be characterised as weak.

### 2.2.7 Redfish

Gradual increasing of dense concentrations as well as total distribution area was observed in the central part of the Barents Sea and to the west and north of Spitsbergen. The abundance was higher than in the last ten years but not above the long-term average.

### 2.2.8 Greenland halibut

0 -group Greenland halibut were only found in low concentrations west and north of Spitsbergen. The total abundance index is much weaker than in 2004 and below the average level. Although the distribution is not completely covered, the 2005 yearclass of Greenland halibut seems to be poor.

### 2.2.9 Long rough dab

No areas with dense concentrations were found. Scattered densities were distributed mainly in eastern part of the Barents Sea and in larger areas than previous years. A slight increase of scattered distributions in the Spitsbergen area were also observed. The 2005 yearclass seems to be weak.

### 2.2.10 Wolffish

As in 2004, wolffish were only found in scattered concentrations around Spitsbergen, and in the south-eastern part of the Barents Sea. Additionally, a small area was found near the Norwegian coast. No index is calculated for these species and due to the low concentration, a distribution map was not found necessary.

### 2.2.11 Sandeel

In the south-eastern part of the Barents Sea, areas with dense and scattered registrations had increased significantly increased compared to 2004 and was similar to the distribution in 2003. In the central region there was only one area with scattered concentration. No index is calculated for this species and due to the low concentration, a distribution map was not found necessary.

### 2.2.12 Gonatus

0 -group Gonatus fabricii were found only in two small areas, one west of Spitsbergen and another in the western part of the Barents Sea. No index is calculated for this species and due to the low concentration, a distribution map was not found necessary.

### 2.3 Distribution and abundance of pelagic fish

Appendix 3 lists the number of fish sampled during the survey.

### 2.3.1 Capelin

### 2.3.1.1 Distribution

The geographical density distribution of the total stock and for age 1 fish are shown in Figs. 2.3.1 and 2.3.2. Total distribution of capelin was located in the central and south-eastern parts of the Barents Sea. The main concentrations were found between $74^{\circ} 40^{\prime}$ and $78^{\circ} \mathrm{N}$ and from $26^{\circ}$ to $45^{\circ} \mathrm{E}$. Small isolated areas with very scattered echo recordings were located to the west of Spitsbergen and northwards of $79^{\circ} \mathrm{N}$ between $38^{\circ}$ and $47^{\circ} \mathrm{E}$. The northern boundary of the main distribution area was located at near the same latitude as it was found last year and extended north to $78^{\circ} 40^{\prime} \mathrm{N}$ to the east of Spitsbergen. Small scattered echo recordings were observed even further north; up to $81^{\circ} 40^{\prime} \mathrm{N}$ near $40^{\circ} \mathrm{E}$. In areas with higher densities of larger capelin large numbers of harp seals and humpback whales were observed. Young capelin were distributed mainly to the south of $76^{\circ} \mathrm{N}$ in scattering layers near the bottom at daytime and near surface during night. In south-eastern part there were often caught significant quantity of young capelin, where echo-recordings were absent. (See section 4, experimental issues).

Echogram of capelin distribution is shown in Figure 2.3.3.

### 2.3.1.2 Abundance estimate and size by age

A detailed stock size estimate is given in Table 2.3.1, and the time series of abundance estimates is summarized in Table 2.3.2. The main results of the abundance estimation in 2005 are summarised in the text table below. The 2004 estimate is shown on a shaded background for comparison.

Summary of stock size estimates for capelin.

| Year class |  | Age | Number ( $\mathbf{1 0}^{9}$ ) |  | Mean weight (g) |  | Biomass ( $10^{\mathbf{3}} \mathrm{t}$ ) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2004 | 2003 | 1 | 26.9 | 51.2 | 3.7 | 3.8 | 99.6 | 195.3 |
| 2003 | 2002 | 2 | 13.0 | 24.8 | 14.3 | 11.9 | 185.9 | 293.9 |
| 2002 | 2001 | 3 | 1.8 | 5.6 | 20.8 | 21.5 | 36.8 | 121.4 |
| 2001 | 2000 | 4 | 0.07 | 0.7 | 25.8 | 24.2 | 1.7 | 17.4 |
| Total stock in: |  |  |  |  |  |  |  |  |
| 2005 | 2004 | 1-4 | 41.8 | 82.3 | 7.8 | 7.6 | 324.0 | 628.0 |
| Based on TS value: $19.1 \log \mathrm{~L}-74.0$, corresponding to $\sigma=5.0 \cdot 10^{7} \cdot \mathrm{~L}^{1.91}$ |  |  |  |  |  |  |  |  |

The total stock is estimated at about 0.3 million tonnes, about $50 \%$ lesser than the stock estimated last year. About $54 \%$ (174 thousand tonnes) of this stock is above 14 cm and considered to be maturing. The 2004 year class (1-group) consists, according to this estimate, of about 27 billion individuals. This estimate is about $50 \%$ lower than that obtained for the 1 group last year. The mean weight is estimated at 3.7 g , which is near the same as that measured last year, and the long-term average. The biomass of the 2004 year class is about 0.1 million tonnes. It should be kept in mind that, given the limitations of the acoustic method concerning mixed concentrations of small capelin and 0 -group fish and near-surface distribution, the 1 -group estimate might be more uncertain than that for older capelin.

The estimated number of fish in the 2003 year class (2-group) is about 13 billion, about half the size of the 2002 year class measured last year. The mean weight at this age is $14.3 \mathrm{~g}(11.9$ g in 2004), and consequently the biomass of the two years old fish is about 0.2 million tonnes. The mean weight is higher than in recent years and is 3.9 g above the long-term average (Table 2.3.2).

The 2002 year class is estimated at about 1.8 billion individuals with mean weight 20.8 g , giving a biomass of about 0.04 million tonnes. The mean weight is lower than that for the 2004, but is 2.2 g above the long-term average. The 2001 year class (now 4 years old) is estimated at 0.07 billion individuals. With a mean weight of 25.8 g this age group makes up only about 2 thousand tonnes. A few capelin older than four years were found.

Since 2003 the joint Russian-Norwegian 0-group and pelagic fish surveys became a part of an ecosystem survey. In addition to pelagic trawl stations a lot of bottom trawl stations were included. It allows to investigate to what extent the biomass of capelin is underestimated due to that especially older fish are distributed close to the bottom and could not be seen by echosounder. A new time series of capelin assessment which has been started in 2004, and including the "bottom" component of the stock has been continued. Results of capelin bottom component assessment by a swept area method will included in volume 2 of joint survey report. "Traditional" capelin index time series based on acoustic estimation only and used for capelin stock assessment and reference points were continued without changes.

### 2.3.1.3 Mortality

Table 2.3.4 shows the number of fish in the various year classes, and their "survey mortality" from age one to two. As there has been no fishing on these age groups, the figures for total mortality constitute natural mortality only, and probably reflect quite well the predation on capelin. As can be seen from the table, the mortality was high prior to 1988, but then a substantial decrease occurred in 1988-89. This coincided with a considerable increase in the stock size caused by the rich 1989 year class. From 1990, the mortality again increased, up to $85 \%$ in 1992-93. This increase is in accordance with the observation of an increasing stock of cod, which were preying on a rapidly decreasing stock of capelin. The mortalities calculated for the period 1996-2002 varied between 20 and 52\% and indicate a somewhat lower level of mortality. In 2003 a considerable increased natural mortality was observed, at the level (around 85\%) observed in 1985-86 and in 1992-93 and this high level was continued from 2003 to 2005. The results of the calculation for the year classes 1988, 1992, and 1994 shows, however, that either the one-group are underestimated or the two-group is overestimated these years. Knowing that the measurement of the 1 -group is more uncertain than the older age groups due to limitations in the acoustic method, the first mentioned possibility is the most probable.

### 2.3.2 Polar cod

Compared to recent years, the polar cod distribution was almost completely covered. Only in the northern areas a definite boundary of the polar cod distribution area was not found. During the trawl survey for Greenland halibut in the areas around Spitsbergen and between Novaja Zemlja - Frans Josef Land, considerable amounts of polar cod was caught in bottom trawl in the studied areas. This situation is common during the autumn, when the polar cod stock is widely distributed in the northern part of the Barents Sea.

### 2.3.2.1 Distribution

The geographical density distribution of the total stock and for age 1 fish are shown in Figs. 2.3.4 to 2.3.5. The densest registrations of polar cod were found in a wide area between $73^{\circ}$ $76^{\circ} \mathrm{N}$ and $42^{\circ}-53^{\circ} \mathrm{E}$. Main centres of gravity were observed along $74^{\circ} 30^{\prime} \mathrm{N}$ between $42^{\circ}-$ $53^{\circ} \mathrm{E}$ and at $75^{\circ} 30^{\prime} \mathrm{N}, 43^{\circ} \mathrm{E}$. This species had a wide distribution, mainly to the east of $37^{\circ} \mathrm{E}$. Local concentrations were registered around Spitsbergen also. Figure 2.3 .6 shows typical acoustic registrations of polar cod.

### 2.3.2.2 Abundance estimation

The stock abundance estimate by age, number, and weight was calculated using the same computer program as for capelin. The geographical density distribution of polar cod is shown in Figs. 2.3.4-2.3.5.

A detailed estimate is given in Table 2.3.5, and the time series of abundance estimates is summarized in Table 2.3.6. The main results of the abundance estimation in 2005 are summarised in the text table below. The 2004 estimate is shown on a shaded background for comparison.

## Summary of stock size estimates for polar cod

| Year class |  | $\frac{\text { Age }}{1}$ | Number ( $10^{9}$ ) |  | Mean weight (g) |  | Biomass ( $\left.10^{3} \mathrm{t}\right)$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2004 | 2003 |  | 71.7 | 99.4 | 8.7 | 6.3 | 626.6 | 627.1 |
| 2003 | 2002 | 2 | 57.1 | 22.8 | 18.0 | 17.8 | 1028.2 | 404.9 |
| 2002 | 2001 | 3 | 3.7 | 2.6 | 32.5 | 31.3 | 120.2 | 82.2 |
| 2001 | 2000 | 4 | 0.2 | 0.4 | 43.6 | 55.3 | 7.6 | 24.6 |
| Total stock in |  |  |  |  |  |  |  |  |
| 2005 | 2004 | 1-4 | 132.9 | 125.3 | 13.6 | 9.1 | 1803.3 | 1143.8 |
| Based on TS value: $21,8.1 \log \mathrm{~L}-72.7$, corresponding to $\sigma=6.7 \cdot 10^{7} \cdot \mathrm{~L}^{2.18}$ |  |  |  |  |  |  |  |  |

The number of individuals in the 2004 year class (the one-year-olds) is about $28 \%$ lower than the one- group measured last year, but their mean weight is 2.4 gram higher. The biomass is, therefore, near the same level as that of the one-year-olds measured last year. The abundance of the 2003 year class (the two-year-olds) is 57.1 billions. This is almost 2.5 times higher than the two-group found last year with about the same mean weight. The biomass has, therefore, increased 2.5 times compared to the 2002 year class estimated last year. The three-years-old fish (2002 year class) is about 3.7 billions that is $42 \%$ larger than the three-group estimated last year and has 1.2 g higher mean weight. Consequently, the biomass of this age group has increased with about $46 \%$ compared to that for the corresponding age group during the 2004 survey. The four-year-olds (2001 year class) are scarcely found and even less than in last year. The total stock, estimated at 1.8 million tonnes, is at the same level as in 2001 and 1.6 times larger than the biomass estimated last year. The reason for the dramatic increase in biomass for polar cod might be that the area of distribution was much better covered this year compared to last year.

### 2.3.2.3 Mortality

Table 2.3.7 shows the "survey-mortality rates" of polar cod in the period 1985 to 2005. The mortality estimates are unstable during the whole period. Although unstable mortalities may indicate errors in the stock size estimation from year to year, the impression remains that there is a considerable total mortality on young polar cod. Prior to 1993, these mortality estimates
represent natural mortality only, as practically no fishing took place. In the period 1993 to 2005 catches were at a level between 0 and 50000 tonnes. Since there has been a minimum landing size of 15 cm (from 1998, 13 cm ) in that fishery, a considerable amount of this could consist of two- and even one-year-olds, and this may explain some, but only a small part of the high total mortality. From 2003 to 2004 there are negative survey mortalities both for age groups 1-2 and for 2-3, confirming the impression expressed in the 2003 report that the 2003 estimate for various reasons was an underestimate.

### 2.3.3 Herring

The youngest age groups (age $0+$ to $3+$ ) of the Norwegian spring spawning herring stock are found in the Barents Sea at irregular intervals. It is difficult to assess the stock size during autumn, due to various reasons. The age groups 1-3 are found mixed with 0 -group herring and other 0 -group fish, and these age groups are difficult to catch in the sampling trawl used during this survey. Besides, the herring schools are partly found near the surface, above the range of the echo sounders. The stock size estimates of herring are therefore considered less reliable than those for capelin and polar cod.

### 2.3.3.1 Distribution

The distribution of young herring is shown in Figure 2.3.7. According to the distribution herring was divided into east and west components. Eastern juvenile herring with predominance of 1 year olds were distributed over a large area between $25^{\circ}$ and $44^{\circ} \mathrm{E}$ and up to $75^{\circ} \mathrm{N}$. West of $25^{\circ} \mathrm{E}$ there were dominated 3 year olds and older herring dominated. Aggregations with highest density of young herring were recorded in the southern part of the sea between $32^{\circ}$ and $43^{\circ} \mathrm{E}$. Further east of $46^{\circ} \mathrm{E}$ as in 2004 there were not found any registrations east of $46^{\circ} \mathrm{E}$. The distribution area of herring in 2005 resembles that of the past few years.

### 2.3.3.2 Abundance estimation

The estimated number and biomass of eastern (east of $25^{\circ} \mathrm{E}$ ) herring from the Barents Sea per age- and length group is given in Table 2.3.8. The main results of the abundance estimation in 2005 are summarised in the text table below. The 2004 estimate is shown on a shaded background for comparison.

Summary of abundance estimates of the portion of the herring stock found in the Barents Sea.

| Year class |  | $\frac{\text { Age }}{1}$ | Number ( $\mathbf{1 0}^{9}$ ) |  | Mean weight (g) |  | Biomass ( $10{ }^{\mathbf{3}} \mathrm{t}$ ) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2004 | 2003 |  | 46.4 | 12.3 | 21.2 | 28.5 | 983.7 | 406.4 |
| 2003 | 2002 | 2 | 16.2 | 36.5 | 65.2 | 74.7 | 1054.5 | 2.725 .3 |
| 2002 | 2001 | 3 | 7.0 | 0.9 | 114.0 | 118.3 | 795.2 | 106.6 |
| Total stock in: |  |  |  |  |  |  |  |  |
| 2005 | 2004 | 1-3 | 69.5 | 51.7 | 40.8 | 62.9 | 2833.4 | 3.251 .9 |

Based on TS value: $20.0 \log \mathrm{~L}-71.9$, corresponding to $\sigma=8.1 \cdot 10^{-7} \cdot \mathrm{~L}^{2.00}$
Total abundance was estimated at $69 \times 10^{9}$ fish and biomass at $2.8 \times 10^{6} \mathrm{t}$. The majority of fish (about $67 \%$ by number) was from the 2003 year class. According to these results, the 2001 year class has left the Barents Sea and was found during survey in Norwegian Sea. Incompatibility between age 2 in this year and age 1 in the previous year may be explained by underestimation of young herring below 12 cm length in 2004. It has been strong mix with 0 group, so this length limit ( 12 cm ) was determined.

### 2.3.4 Blue whiting

In the southwestern part of the Barents Sea blue whiting were observed as in last year. In recent years, the blue whiting have seemingly expanded its distribution area towards northeast, partly entering the Barents Sea. A quantitative estimation of this species has normally not been attempted during this survey, since only a small part of the total distribution area of this species is covered. Nevertheless, this species is now a major component of the Barents Sea ecosystem, and consequently, it was decided to make a stock size estimate of the covered part of the stock during the current survey. The target strength used for blue whiting is uncertain, and the estimate should to a greater extent than the other estimates be considered as a relative quantity only.

### 2.3.4.1 Distribution

The distribution of blue whiting (all age groups) is shown in Figure 2.3.8. As in 2004 the distribution area stretches from the western border of the covered area east to a line between North Cape and Spitsbergen. In addition, lower concentrations were detected along the coast of Finnmark east to Vardø.

### 2.3.4.2 Abundance estimation

The estimated number and biomass of blue whiting per age- and length group is given in Table 2.3.8. Total abundance was estimated at $15 \times 10^{9}$ fish and biomass at $1.1 \times 10^{6} \mathrm{t}$, compared to $1.4 \times 10^{6} \mathrm{t}$ in 2004. The main bulk of this stock component consisted of 20002004 yearclasses at age 1-5. Older fish at age 6-9 were found in small quantites and insignificant numbers of fish up to 15 years of age were found.

### 2.4 Demersal fish

Figures 2.4.1-2.4.15 and Tables 2.4.1-2.4.11 show the distribution and abundance of demersal fish. Appedix 3 lists the numer of fish sampled during the survey.

### 2.4.1 Cod (Fig. 2.4.1 and Table 2.4.1)

The total distribution area of cod in the Barents Sea was covered. At this time of the year, towards the end of the feeding period, the distribution of cod is wide. Cod reach the limits of its natural habitat and single fishes were caught as far north as $80-82^{\circ} \mathrm{N}$. Two main concentrations were observed; one in the south-eastern areas from Murman Shallow to the slope of Goose Bank and Novaya Zemlya archipelago, and the other in the northern area south-eastwards and eastwards of Spitsbergen archipelago. Compared to the observations last year very small changes were found in the distribution patterns in 2005 . The abundance of cod between 10 and 40 cm was about the same as last year, while the abundance of cod $>40$ cm was considerably lower than last year.

### 2.4.2 Haddock (Fig 2.4.2 and Table 2.4.2)

The haddock distribution was covered well by the survey. Haddock were distributed in the warm water masses and along the coast of Norway and Russia between $17-47^{\circ} \mathrm{E}$ and to a lesser degree to the west of Spitsbergen. Dense concentrations were found between $35-44^{\circ} \mathrm{E}$ along Murman Coast and to the north of Norwegian coast. The catches of haddock as well as the distribution area increased considerably in 2005 comparing to the survey in 2004 . The
abundance of haddock increased considerably from last year. Most of the increase is in the length groups $15-24 \mathrm{~cm}$, corresponding mainly to age 1 fish.

### 2.4.3 Saithe (Fig 2.4.3)

Saithe were distributed in the warm water masses and along the coast of Norway and Russia between $18-40^{\circ} \mathrm{E}$, with a single observation as far east as $47^{\circ} \mathrm{E}$. The catches of saithe were observed near Spitsbergen ( $77-78^{\circ} \mathrm{N}$ ). Compared to the survey in 2004, the eastern border of its distribution and the area with the highest densities moved eastwards in 2005.

### 2.4.4 Greenland halibut (Fig 2.4.4 and Table 2.4.3)

Mainly young age groups of Greenland halibut were observed because the adult part of the stock was distributed outside of the survey area. Main concentrations were located in the deeper part of the Spitsbergen slope and in the area between Spitsbergen and Franz Josef Land archipelago, as well as between Bear Island and Hopen Island. Catches of Greenland halibut were taken as far east as $61^{\circ} \mathrm{E}$ and north as $82^{\circ} \mathrm{N}$. The catches of Greenland halibut increased in all areas in 2005 compared to the survey in 2004. The abundance of Greenland halibut increased considerably, mainly due to an increase in the abundance of $10-19 \mathrm{~cm}$ fish.

### 2.4.5 Redfish (Sebastes marinus and Sebastes mentella) (Fig. 2.4.5-2.4.6 and Table 2.4.4-2.4.5)

Redfish were only distributed in the western and northern parts of the survey area. Most dense concentrations were located along the shelf slope from the Norwegian coast to west of Spitsbergen. In all other areas, including the area between Spitsbergen and Franz Josef Land archipelago, redfish was only found in scattered densities. The abundance of S. mentella was close to that estimated last year. The abundance of S. marinus was slightly higher than last year, but is very low compared to the abundance of $S$. mentella.

### 2.4.6 Long rough dab (Fig. 2.4.7 and Table 2.4.6)

The distribution of long rough dab was wider than the distribution of other species. It was practically found in all areas, and its catches were quite significant in most cases. Catches of LRD were taken as far east as $62^{\circ} \mathrm{E}$ and north as $82^{\circ} \mathrm{N}$. The abundance of long rough dab decreased slightly compared to 2004.

### 2.4.7 Wolffishes (Fig. 2.4.8-2.4.10 and Table 2.4.7-2.4.9)

The abundance of Atlantic wolffish was the same as last year, while the abundance of spotted and northern wolffish decreased slightly.

### 2.4.8 Non-target species (Figs 2.4.11-2.4.15, Tables 2.4.10-2.4.12)

Totally 89 fish species from 30 families occurred in the trawl catches during the survey. A list of the species and ecological and zoogeographic characteristics is given in Appendix 4. The highest number of species was observed in the families Zoarcidae (11 species), Gadidae ( 9 species), Cottidae ( 8 species) and Pleuronectidae ( 7 species).

Five species were chosen as indicator species to demonstrate the distribution patterns of fishes from the different zoogeographic groups - mainly Arctic sea tadpole Careproctus reinhardti, arcto-boreal Atlantic poacher Leptagonus decagonus, mainly boreal hook-ear sculpin

Artediellus atlanticus and thorny skate Amblyraja radiata and boreal european Norway pout Trisopterus esmarkii.

### 2.4.8.1 Sea tadpole (Fig. 2.4.11)

This species was distributed mostly in the central and northern Barents Sea. The biggest catches were observed near the southern and eastern coast of Spitsbergen and in the area between Spitsbergen and Franz Josef Land archipelago.

### 2.4.8.2 Atlantic poacher (Fig. 2.4.12, Table 2.4.10)

The species was distributed mostly in the central and northern Barents Sea. The biggest catches were observed near the southern and eastern coast of Spitsbergen and in the central open part of the Barents Sea. The species is practically absent in the warm water in the southwestern part of the sea. Its distribution is similar to the distribution of cold water. The abundance decreased slightly from 2004 to 2005.

### 2.4.8.3 Hook-ear sculpin (Fig. 2.4.13)

The species is widely distributed in the Barents Sea. The biggest catches were observed in the northern Barents Sea (near the southern and eastern coast of Spitsbergen and in the area between Spitsbergen and Franz Josef Land archipelago).

### 2.4.8.4 Thorny skate (Fig. 2.4.14, Table 2.4.11)

The species was widely distributed in the Barents Sea excluding the northern areas near Franz Josef Land archipelago, as well as the western Norwegian coast. The biggest catches were observed in the central part of the Barents Sea, in the area between Spitsbergen and the Bear Island as well as in the southeastern part of the Barents Sea near the Kanin Peninsula.

### 2.4.8.5 Norway pout (Fig 2.4.15)

The species was distributed only in the southwestern part of the Barents Sea near Norway and to a lesser extent along the Murman coasts. Its distribution is similar to the distribution of the warmest Atlantic water. Single specimens were found near the southern coast of Spitsbergen.

### 2.5 Phytoplankton

Data on fluorescence, chlorophyll a, nutrients and phytoplankton species composition data are now being processed and analyzed at the IMR laboratory. A summary and some preliminary results will be available for volume 2 of the report.

### 2.6 Zooplankton

The map of zooplankton sampling localities and sampling gear (Russian and Norwegian vessels) is shown in figure 2.3. The main results of zooplankton observations will be presented in volume 2 of Joint Ecosystem Survey Report after working up data in the laboratories.

From figure 2.3 it is apparent that the investigated area is covered reasonably well as seen from a zooplankton point of view. The table below gives an overview of total zooplankton hauls for different types of zooplankton sampling gear during the Ecosystem survey.

Total number of zooplankton hauls obtained during the Norwegian and Russian surveys in the Barents Sea in August-October 2005.

| Net | Norwegian ships |  | Russian ships |  |
| :---: | :---: | :---: | :---: | :---: |
|  | «G.O.Sars» | «J.Hjort» | «F.Nansen» | «Smolensk» |
| WP-2 | 201 | 123 | 21 | - |
| Juday | 10 | - | 228 | 101 |
| MOCNESS | 34 | 27 | - | - |

In figure 2.6.1 an overview of zooplankton biomass (wet-weight $\mathrm{mg} / \mathrm{m}^{3}$ ) from the Russian vessel Fridtjof Nansen in the upper $0-50 \mathrm{~m}$ by Juday net is shown. We observe that biomass from mid August to September in different areas of the survey were rather high and that a marked downward seasonal shift in the vertical distribution of zooplankton also took place (not shown).

Biomass data collected by Norwegian and Russian vessels from stations where WP2 and Juday both have been used will be compared as soon as all relevant data are available. Secondly, species composition and abundance from WP2 and Juday nets collected at the same stations in 2004 and 2005 will be analyzed and compared. Preliminary analysis has shown a significant variability in stage composition of key species of Calanus. A more extensive comparison and analysis should therefore be undertaken to help quantify this variability, based on data from 2004 and 2005. The agreement on comparative collection of zooplankton samples by WP-2 and Juday net on Norwegian and Russian vessels (c.f. Meeting in April 2005) will be followed up by both parties with regard to working up samples, exchange of raw data, analysis and publication in relevant reports or international refereed journals. It is suggested that the agreement is strengthened with additional sampling and also new approaches in future surveys with the ultimate goal of a unified sampling approach.

It is recommended, based on experience during field sampling in 2005 and from preliminary comparisons based on data from 2004, that a Bongo-like rig should be built that can hold both a WP2 and a Juday net for better performance and more efficient comparisons between the sampling gear. This way the problems concerning variability between consecutive net hauls can be reduced.

### 2.7 Sea mammals and birds

A total of 622 observations of 5564 individuals of marine mammals comprising 17 species were recorded from RVs "Johan Hjort", G.O. Sars, "F. Nansen", "Smolensk" and the aircraft "Arktika". Number of marine mammals observed by species is listed in Table 2.7.1. The most abundant species in terms of individuals were harp seals ( $49 \%$ of total number of individuals observed), due to one observation of 2000 individuals made on board "F. Nansen", and dolphins, of which white-beaked dolphins were the predominant species ( $23 \%$ of total number of individuals observed). Of the baleen whales ( $10 \%$ of total number of individuals observed), minke and fin whales were most numerous (Table 2.7.1).

Minke whales had the widest distribution among the baleen whales as they were observed both on and off the shelf and throughout the survey area (Fig. 2.7.1). Humpback and fin whales were observed on the shelf or the shelf break west of Spitsbergen, and while humpback whales were observed both in the northern and southern Barents Sea, fin whales were more restricted to the central and northern Barents Sea. Sei whales, normally considered as a southern deep-sea species, were observed both west and east of Svalbard and in the
$\overline{\text { central Barents Sea. Finally, one observation of the rare bowhead whale was recorded east of }}$ Svalbard in the northern Barents Sea. Both sei and bowhead whales were observed in open water, about 120 nautical miles from the sea ice edge. The dolphins, predominantly comprising white-beaked dolphins, were observed throughout the Barents Sea. In contrast, sperm whales were only observed off the shelf break, mainly south of Bear Island (Fig. 2.7.2). Harp seals were observed east of Svalbard only, close to the sea ice edge (Fig. 2.7.2).

Around 6000 observations of 115218 sea birds comprising 29 species were recorded onboard the vessels "G. O. Sars", "Johan Hjort", "F. Nansen" and the aircraft "Arktika" (Table 2.7.2). The procellarids were the most abundant species group in terms of individuals observed (59 586) due to high abundances of northern fulmars, while the alcids were the most abundant group in terms of observations ( 7773 ). The most abundant single species was the northern fulmar with 59499 individuals recorded (Table 2.7.2).

The alcids were observed throughout the study area, but the abundance and species distribution varied geographically (Fig. 2.7.3). Number of individuals increased northwards and eastwards. In the south-western Barents Sea puffins and common guillemots dominated, the central areas were dominated by brünnich's guillemots and the northern areas by brunnich's guillemots, little auks and black guillemots. Little auks were generally closer to Svalbard than the brunnich's guillemots. Furthest north black guillemots were observed in high concentrations.

The gulls and the northern fulmars are ship-followers, and hence their observed distribution will be influenced by the presence of the ships. Figure 2.7.4 show the distribution of these species as observed from the aircraft "Arktika" (mainly northern fulmars and kittiwakes) and the vessels "G.O. Sars" and "Johan Hjort" (based on counts every half-hour). Northern fulmars were observed in most of the study area, although they dominated the abundances in the western part. Kittiwakes dominated the abundances in the eastern and northern areas. Great black-backed gulls and herring gulls were observed in the southern Barents Sea, while ivory gulls were observed only in the extreme north. A few glaucous gulls were observed in the central Barents Sea, around Bear Island and southern Svalbard.

Four species of skuas were observed; great, pomarine, long-tailed and arctic skua (Fig. 2.7.5). Numbers of skuas increased towards the north and east, with arctic skuas dominating the southern areas and pomarine and great skuas dominating the northern areas.

The observed distributions of marine mammals and birds shown in Figs. 2.7.1-2.7.5 are not effort corrected. Due to unfavourable weather and light conditions observers were active parts of the survey time only, which may yield biased distribution maps.

### 2.8 Benthos investigations

The five vessels involved in the ecosystem survey sampled in different areas of the Barents Sea. Bottom trawl (Campelen) was used on all ships (see table below) in the whole survey area, but only F. Nansen and GO Sars had taxonomic experts participating on the cruise. The southeastern part of the survey area and the area around Svalbard was sampled with grab (van Veen) and small trawls (Sigsby and Beam trawl). Video rig and epibenthic sled (RP sled) were only used onboard GO Sars (see table 2.8.1).

The samples collected with all gears except bottom trawl are currently being processed at PINRO and IMR. The bycatch data from the Russian vessels is already punched into databases. Unfortunately, the recorded bycatch data from GO Sars is not completely finished
at this point. A preliminary species list of bycatch invertebrates recorded onboard the different ships is provided in Appendix 5.

There was a tendency to decreased number of species in larger trawl samples (Fig. 2.8.1).
This can best be explained by the fractionation of large samples. More analysis of the bycatch data is needed to understand the potential and limitation of this survey technique.

The number of identified taxa in the bycatch material was in total 313 (see table below). Only 10 taxa were recorded on all five vessels. Of these, only two were identified to species level (Pandalus borealis and Sclerocrangon ferox).

Figure 2.8 .2 shows the biomass distribution of benthic invertebrates in the Barents Sea caught as by-catch in the bottom trawl.

Number of identified and unidentified invertebrate species recorded in the bycatch onboard the five research vessels involved in the ecosystem survey.

Vessels

| Equipment | GO Sars | Johan Hjort | Jan Mayen | Fritjof Nansen | Smolensk |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Number of identified <br> taxa | 117 | 72 | 40 | 176 | 77 |
| Identified species (\% <br> of total taxa number) | 34 | 42 | 7 | 71 | 58 |

## King Crab (Paralithodes camtschaticus) - figure 2.8.4

The distribution area for king crab was mainly located close to the coast (between $27-45^{\circ} \mathrm{E}$ ). High catches of king crab were caught in the eastern area. The westernmost record was from north of Porsangerfjorden.

## Snow crab (Chionoecetes opilio) (figure 2.8.3)

Snow crab was registrated only on two stations between $30^{\circ}$ and $40^{\circ} \mathrm{E}$, and $71^{\circ}$ and $73^{\circ} \mathrm{N}$. Standardised to hours of trawling the catch was around $2-3 \mathrm{~kg}$.

## Shrimp (Pandalus borealis) figure 2.8.5

Shrimp was distributed practically all over the surveyed areas. The larger size shrimp were mainly found in the northern part of the survey area.

## 3 ECOLOGICAL CONSIDERATIONS

During the ecosystem survey major components of the ecosystem are monitored synoptically. Traditionally the results of these are presented and treated separately, but then the potential to gleam insight into the ecology of the Barents Sea ecosystem is not utilized to the full extent. The synoptic data from this ecosystem survey provides a unique opportunity to study ecological interactions between species and the relationships between the physical processes and species distribution.

There is a great need for such ecological knowledge when implementing ecosystem-based management. Therefore preliminary analyses of ecological interactions will be included in volume 2 of the survey report. However, the ecological analysis cannot be started until data from surveyed components of the ecosystem are available. In volume 2 of the cruise report we plan to carry out the following preliminary ecological analyses: 1) Estimate and map species overlap between for key prey and predator species, 2) Map biodiversity, also in relation to physical processes, 3)Estimate and map species distribution in relationship to physical processes and habitat for key species and processes.

## 4 EXPERIMENTAL WORK. SWEPT AREA METHOD FOR CAPELIN ESTIMATION BY PELAGIC TRAWL.

As known, the acoustic method possibilities for fish detection as in "near the bottom", as in "near the surface" layers, are too much limited according to "the echosounder acoustic dead zone". In this connection the trawl method (or swept area method) is often applied for the density estimation of fish, distributed close to bottom or close to surface.

As in previous years, for the south-east part of the Barents Sea in August 2005 the "close to surface" capelin distribution was typical, especially at night time. It often brought to the situations when the catches of capelin in the near-surface pelagic hauls had achieved several hundreds specimen but acoustic $\mathrm{s}_{\mathrm{A}}$ values was being about zero. So the using of the trawl method for capelin estimation in the near-surface layers looked enough adjustable in this case. Based on the $\mathrm{r} / \mathrm{v}$ "Smolensk" data, the near-surface capelin estimations by the trawl and acoustic methods were made for the south-east part of the Barents Sea.

Acoustic estimation was made by the classical method using the mean $\mathrm{s}_{\mathrm{A}}$ values per WMO squares and of summarized capelin length distribution for the all area. The trawl estimation was made by using of the usual "swept area method", taking in attention the regular distribution of the pelagic hauls positions 35 nm each from other by the formula for each $35 \times 35 \mathrm{~nm}^{2}$ square:

$$
\mathrm{N}_{\mathrm{i}}=\frac{\text { Catch }_{\mathrm{i}} \cdot 1852 \cdot 35 \cdot 35 \cdot \mathrm{~K}_{\mathrm{i}} \cdot \mathrm{~K}_{\mathrm{TR}}}{\mathrm{~L}_{\mathrm{eff}} \cdot \mathrm{D}_{\mathrm{TR}}}
$$

where $\mathrm{N}_{\mathrm{i}}$ - abundance of the i-length group fishes inside of each $35 \times 35 \mathrm{~nm}^{2}$ square;
Catch $_{i}$ - the number of the i-length group fishes in the trawl catch;
$\mathrm{K}_{\mathrm{i}}$ - theoretical length-dependant catchability index assumed for the sampling trawl (Mamylov, 2004);
$\mathrm{K}_{\mathrm{TR}}=\left(\mathrm{H}_{\mathrm{TR} \max }+\mathrm{dH}_{\mathrm{TR}}-\mathrm{H}_{\mathrm{TR} \min }\right) / \mathrm{dH}_{\mathrm{TR}}$ (the number of trawl horizons for each haul);
Leff - the horizontal trawl opening assumed to be equal 15 meters
$\mathrm{D}_{\mathrm{TR}}$ - distance of trawling (nm).
The results of the capelin estimation by the acoustic and trawl methods are in the table below.

It's seen that the trawl method gives more than 3 times higher capelin abundance compared to the acoustic method.

Capelin estimation results in the south-east part of the Barents Sea by the acoustic and the pelagic trawl methods (Total area 127088 sq.nm)

| L,cm | q | w, g | Acoustic estimation |  | Trawl estimation |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | N, 10^6 | w, tonn | N, 10^6 | W, tonn |
| 5.7 | 92 | 0.5 | 47.9 | 25.6 | 163.8 | 87.5 |

## Tables

Table 2.1.1. Mean water temperature ${ }^{1)}$ in the main parts of standard oceanographic sections in the Barents Sea and adjacent waters in August-September 1965-2005. The sections are: Kola ${ }^{2)}$ (column 1-3), Kanin (column $4^{3)}-5^{4)}$ ), North Cape-Bear Island (column $6^{5)}$ ), Bear Island - West (column $7^{6}$ ), Vardo - North (column 8), Fugløya - Bear Island (column 9).

| Year | Section and layer (depth in metres) |  |  |  |  |  |  |  |  |

| Average | 7.5 | 3.9 | 4.8 | 4.3 | 3.3 | 5.8 | 4.7 | 4.2 | 5.8 |

${ }^{1)}$ Earlier presented temperatures have been slightly adjusted (Tereshchenko, 1992).
${ }^{2)}$ Murmansk Current; Kola section ( $70^{\circ} 30^{\prime} \mathrm{N}-72^{\circ} 30^{\prime} \mathrm{N}, 33^{\circ} 30^{\prime} \mathrm{E}$ )
${ }^{3)}$ Kanin section $\left(68^{\circ} 45^{\prime} \mathrm{N}-70^{\circ} 05^{\prime} \mathrm{N}, 43^{\circ} 15^{\prime} \mathrm{E}\right)$
${ }^{4)}$ Kanin section $\left(71^{\circ} 00^{\prime} \mathrm{N}-72^{\circ} 00^{\prime} \mathrm{N}, 43^{\circ} 15^{\prime} \mathrm{E}\right)$
${ }^{5)}$ North Cape Current; North Cape-Bear Island section ( $71^{\circ} 33^{\prime} \mathrm{N}, 25^{\circ} 02^{\prime} \mathrm{E}-73^{\circ} 35^{\prime} \mathrm{N}, 20^{\circ} 46^{\prime} \mathrm{E}$ )
${ }^{6)}$ West Spitsbergen Current; Bear Island - West section ( $74^{\circ} 30^{\prime} \mathrm{N}, 06^{\circ} 34 \mathrm{E}-15^{\circ} 55^{\prime} \mathrm{E}$ ).
${ }^{7)}$ The temperature wasn't evaluated because the Bear Island - West section was carried out with station positions that differed from the conventional.

Table 2.2.1. Abundance indices (area method) of 0 -group fish in the Barents Sea and adjacent waters in August-September 1965-2005

| Year | Capelin ${ }^{1}$ | $\mathrm{Cod}^{2}$ | Haddock ${ }^{2}$ | Herring ${ }^{3}$ | Polar cod |  | Redfish | Greenland halibut | Long rough dab |

## APPENDIX 2

## Ecosystem survey 2005

SPHERE CALIBRATION OF ECHOSOUNDERS EK-500, ER60
(on copper sphere CU60, TS $=33,6 \mathrm{~dB}$, at frequency 38 kHz )

| Research vessel | G.O. Sars | Johan Hjort | Jan-Mayen | Smolensk | F. Nansen |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Type of echosounder | ER60 | ER60 | ER60 | EK60 | EK60 |
| Date | 14.04 .2005 | 18.08 .2005 | 15.08 .2005 | 11.08 .2005 | 13.10 .2004 |
| Place | Ugdalseide | Coles bay <br> Spitsbergen | Coles bay, <br> Spitsbergen | $69^{\circ} 13^{\prime} \mathrm{N}$ <br> $35^{\circ} 10^{\prime} \mathrm{E}$ | $69^{\circ} 13^{\prime} \mathrm{N}$ <br> $35^{\circ} 10^{\prime} \mathrm{E}$ |
| Bottom depth (m) | 88 |  | 41 | 42 | 52 |
| Depth to sphere (m) | 20.8 | 19.0 | 37 | 30.57 | 27.4 |
| Temperature ( $\left.{ }^{\circ} \mathrm{C}\right)$ | 3.31 | 3.5 | 1.0 | 10.1 | 3,5 |
| Salinity (\%) | 31.96 | 32.7 | 34.0 | 32.6 | 33,9 |
| TS of sphere (dB) | -33.6 | -33.7 | -33.6 | -33.6 | -33.6 |
| Transducer type | ES38B | ES38B | ES38B | ES38B | ES38B |
| Transducer depth (m) | 5.5 | 0 |  | 0 | 0 |
| Real sphere depth (m) |  | 19.0 |  | 30.57 | 27.40 |
| Sound velocity (m/sec) | 9.321 | 9.782 | 1464.0 | 1453.0 | 1485 |
| Absorption coefficient (dB/km) | 1.024 | 1.024 | 1.024 | 1467 |  |
| Pulse length (Short/Med./Long, <br> ms) | 2.425 kHz |  |  |  | 9.76 |

## APPENDIX 3

## Sampling of fish

|  | Norwegian vessels | Russian vessels | Sum |
| :---: | :---: | :---: | :---: |
| Capelin |  |  |  |
| No of samples | 338 | 220 | 558 |
| Nos. length measured | 10155 | 12470 | 22625 |
| Nos. aged | 2600 | 1077 | 3677 |
| Polar cod |  |  |  |
| No of samples | 405 | 220 | 625 |
| Nos. length measured | 14425 | 64085 | 78510 |
| Nos. aged | 2005 | 1414 | 3419 |
| Herring |  |  |  |
| No of samples | 125 | 75 | 200 |
| Nos. length measured | 4048 | 2805 | 6853 |
| Nos. aged | 680 | 368 | 1048 |
| Blue Whiting |  |  |  |
| No of samples | 196 | 7 | 203 |
| Nos. length measured | 8082 | 2403 | 10485 |
| Nos. aged | 812 | 205 | 1017 |
| Cod |  |  |  |
| No of samples | 530 | 285 | 815 |
| Nos. length measured | 17548 | 8373 | 25921 |
| Nos. aged | 1615 | 1150 | 2765 |
| Haddock |  |  |  |
| No of samples | 474 | 124 | 598 |
| Nos. length measured | 19825 | 4934 | 24759 |
| Nos. aged | 1069 | 283 | 1352 |
| Redfish (Sebastes marinus) |  |  |  |
| No of samples | 65 | 15 | 80 |
| Nos. length measured | 363 | 39 | 402 |
| Nos. taken for age | 166 | 14 | 180 |
| Redfish (Sebastes mentella) |  |  |  |
| No of samples | 200 | 60 | 260 |
| Nos. length measured | 5740 | 888 | 6628 |
| Nos. taken for age | 996 | 1 | 997 |
| Saithe |  |  |  |
| No of samples | 78 | 37 | 115 |
| Nos. length measured | 527 | 87 | 614 |
| Nos. taken for age | 25 | 8 | 33 |
| Greenland halibut |  |  |  |
| No of samples | 464 | 73 | 537 |
| Nos. length measured | 6327 | 12326 | 18653 |
| Nos. taken for age | 681 | 697 | 1378 |
| Atlantic wolffish (Anarhichas lupus) |  |  |  |
| No of samples | 56 | 34 | 90 |
| Nos. length measured | 318 | 73 | 391 |
| Spotted wolffish <br> (Anarhichas minor) |  |  |  |
| No of samples | 48 | 34 | 82 |
| Nos. length measured | 103 | 99 | 202 |
| Northern wolffish <br> (Anarhichas denticulatus) |  |  |  |
| No of samples | 50 | 12 | 62 |
| Nos. length measured | 63 | 14 | 77 |
| Long rough dab |  |  |  |
| No of samples | 388 | 343 | 731 |
| Nos. length measured | 9190 | 24238 | 33428 |

Length measurements include 0 -group samples. Demersal fishes will be aged after the survey.

## APPENDIX 4

List of the Barents Sea fish species caught during the ecosystem survey 2005.

| № | Species | Ecologic group | Zoogeographic group |
| :---: | :---: | :---: | :---: |
| Cephalaspidomorphi |  |  |  |
| Petromyzontiformes |  |  |  |
|  | Petromyzontidae |  |  |
| 1. | Petromyzon marinus Linnaeus, 1758 | Anadromous | Southboreal atlantic |
| 2. | Lethenteron camtschaticum (Tilesius, 1811) | Anadromous | Mainly boreal |
|  | Elasmobranchii |  |  |
|  | Squaliformes |  |  |
|  | Squalidae |  |  |
| 3. | Somniosus microcephalus (Bloch et Schneider 1801) | Near bottom pelagic | Mainly boreal |
|  | Rajiformes |  |  |
|  | Rajidae |  |  |
| 4. | Bathyraja spinicauda (Jensen, 1914) | Bottom | Mainly boreal |
| 5. | Raja clavata Linnaeus, 1758 | Bottom |  |
| 6. | Rajella fyllae (Lütken, 1888) | Bottom | Boreal atlantic |
| 7. | Amblyraja hyperborea (Collett, 1879) | Bottom | Arctic |
| 8. | Amblyraja radiata (Donovan, 1808) | Bottom | Mainly boreal |
|  | Holocephali |  |  |
|  | Chimaeriformes |  |  |
|  | Chimaeridae |  |  |
| 9. | Chimaera monstrosa Linnaeus, 1758 | Near bottom | Boreal european |
|  | Teleostomi |  |  |
|  | Clupeiformes |  |  |
|  | Clupeidae |  |  |
| 10. | Clupea harengus Linnaeus, 1758 | Nerito-pelagic | Mainly boreal |
| 11. | Clupea pallasii suworowi Rabinerson, 1927 | Nerito-pelagic | Mainly boreal |
|  | Salmoniformes |  |  |
|  | Argentinidae |  |  |
| 12. | Argentina silus (Ascanius, 1775) | Bathypelagic | Boreal atlantic |
|  | Osmeridae |  |  |
| 13. | Mallotus villosus (Müller, 1776) | Nerito-pelagic | Mainly boreal |
|  | Salmonidae |  |  |
| 14. | Salmo salar Linnaeus, 1758 | Anadromous | Mainly boreal |
|  | Stomiiformes |  |  |
|  | Sternoptychidae |  |  |
| 15. | Maurolicus muelleri (Gmelin, 1789) | Bathypelagic | Boreal atlantic |
|  | Aulopiformes |  |  |
|  | Paralepididae |  |  |
| 16. | Arctozenus risso (Bonaparte, 1840) | Bathypelagic | Widely distributed |
|  | Myctophiformes |  |  |
|  | Myctophidae |  |  |
| 17. | Benthosema glaciale (Reinhardt, 1838) | Bathypelagic | Mainly boreal |
| 18. | Myctophum punctatum |  |  |
|  | Gadiformes |  |  |
|  | Macrouridae |  |  |
| 19. | Coryphaenoides rupestris Gunnerus, 1765 | Near bottom | Boreal atlantic |
| 20. | Macrourus berglax Lacepede, 1810 | Near bottom | Boreal atlantic |
|  | Gadidae |  |  |
| 21. | Boreogadus saida (Lepechin, 1774) | Cryopelagic | Arctic |
| 22. | Eleginus navaga (Pallas, 1811) | Near bottom pelagic | Arctic |
| 23. | Gadiculus argenteus thori Schmidt, 1914 |  |  |
| 24. | Gadus morhua Linnaeus, 1758 | Near bottom pelagic | Mainly boreal |
| 25. | Melanogrammus aeglefinus (Linnaeus, 1758) | Near bottom pelagic | Mainly boreal |
| 26. | Merlangius merlangus (Linnaeus, 1758) | Near bottom pelagic | Southboreal european |
| 27. | Micromesistius poutassou (Risso, 1826) | Nerito-pelagic | Mainly boreal |
| 28. | Pollachius virens (Linnaeus, 1758) | Nerito-pelagic | Mainly boreal |
| 29. | Trisopterus esmarkii (Nilsson, 1855) | Nerito-pelagic | Mainly boreal |
|  | Lotidae |  |  |

Appendices
Ecosystem survey of the Barents Sea autumn 2005 vol. 1

| 30. | Brosme brosme (Ascanius, 1772) | Near bottom | Mainly boreal |
| :---: | :---: | :---: | :---: |
| 31. | Enchelyopus cimbrius (Linnaeus, 1766) | Near bottom | Boreal atlantic |
| 32. | Gaidropsarus argentatus (Reinhardt, 1838) | Near bottom | Arctic |
| 33. | Gaidropsarus ensis (Reinhardt, 1837) | Near bottom | Boreal atlantic |
| 34. | Molva molva (Linnaeus, 1758) | Near bottom | Boreal atlantic |
| 35. | Phycidae <br> Phycis blennoides (Bruennich, 1768) Lophiiformes | Near bottom pelagic | Southboreal european |
| 36. | Lophiidae <br> Lophius piscatorius Linnaeus, 1758 Gasterosteiformes | Bottom | Southboreal atlantic |
| 37. | Gasterosteidae <br> Gasterosteus aculeatus Linnaeus, 1758 Syngnathiformes | Nerito-pelagic | Mainly boreal |
| 38. | Syngnathidae <br> Syngnathidae spp. <br> Scorpaeniformes |  |  |
|  | Sebastidae |  |  |
| 39. | Sebastes marinus (Linnaeus, 1758) | Near bottom pelagic | Mainly boreal |
| 40. | Sebastes mentella Travin, 1951 | Near bottom pelagic | Mainly boreal |
| 41. | Sebastes viviparus Kröyer, 1844 Cottidae | Near bottom | Boreal atlantic |
| 42. | Artediellus atlanticus Jordan et Evermann, 1898 | Bottom | Mainly boreal |
| 43. | Gymnocanthus tricuspis (Reinhardt, 1830) | Bottom | Mainly arctic |
| 44. | Icelus bicornis (Reinhardt, 1840) | Bottom | Mainly arctic |
| 45. | Icelus spatula Gilbert et Burke, 1912 | Bottom | Arctic boreal |
| 46. | Myoxocephalus scorpius (Linnaeus, 1758) | Bottom | Mainly boreal european |
| 47. | Triglops murrayi Günther, 1888 | Bottom | Boreal atlantic |
| 48. | Triglops nybelini Jensen, 1944 | Bottom | Arctic |
| 49. | Triglops pingelii Reinhardt, 1837 | Bottom | Arctic boreal |
|  | Psychrolutidae |  |  |
| 50. | Cottunculus microps Collett, 1875 | Bottom | Mainly arctic |
| 51. | Cottunculus sadko Essipov, 1937 | Bottom | Arctic |
|  | Agonidae |  |  |
| 52. | Leptagonus decagonus (Bloch et Schneider, 1801) | Bottom | Arctic boreal |
| 53. | Ulcina olrikii (Lütken, 1876) | Bottom | Arctic |
|  | Cyclopteridae |  |  |
| 54. | Cyclopterus lumpus Linnaeus, 1758 | Near bottom pelagic | Mainly boreal atlantic |
| 55. | Eumicrotremus derjugini Popov, 1926 | Bottom | Arctic |
| 56. | Eumicrotremus spinosus (Müller, 1777) Liparididae | Bottom | Arctic |
| 57. | Careproctus ranula (Goode et Bean, 1880) | Near bottom | Arctic |
| 58. | Careproctus reinhardti (Kröyer, 1862) | Near bottom | Arctic |
| 59. | Liparis fabricii Kröyer, 1847 | Near bottom | Arctic |
| 60. | Liparis gibbus Bean, 1881 | Bottom | Mainly arctic |
| 61. | Liparis liparis (Linnaeus, 1766) Perciformes | Bottom | Boreal european |
|  | Zoarcidae |  |  |
| 62. | Gymnelus sp. | Bottom | Arctic |
| 63. | Lycenchelys kolthoffi Jensen, 1903 | Bottom | Arctic |
| 64. | Lycodes esmarki Collett, 1875 | Bottom | Mainly boreal atlantic |
| 65. | Lycodes eudipleurostictus Jensen, 1901 | Bottom | Arctic |
| 66. | Lycodes frigidus Collett, 1878 | Bottom | Arctic |
| 67. | Lycodes pallidus Collett, 1878 | Bottom | Arctic |
| 68. | Lycodes polaris (Sabine, 1824) | Bottom | Arctic |
| 69. | Lycodes reticulatus Reinhardt, 1835 | Bottom | Arctic |
| 70. | Lycodes rossi Malmgren, 1864 | Bottom | Arctic |
| 71. | Lycodes seminudis Reinhardt, 1837 | Bottom | Arctic |
| 72. | Lycodes vahli gracilis Sars, 1867 | Bottom | Mainly boreal european |
|  | Stichaeidae |  |  |
| 73. | Anisarchus medius (Reinhardt, 1837) | Bottom | Boreal atlantic |
| 74. | Lumpenus fabricii (Valenciennes, 1836) | Bottom | Mainly arctic |
| 75. | Lumpenus lampretaeformis (Walbaum, 1792) | Bottom | Mainly boreal european |
| 76. | Leptoclinus maculatus (Fries, 1837) Anarhichadidae | Bottom | Mainly boreal atlantic |
| 77. | Anarhichas denticulatus Kröyer, 1845 | Near bottom | Mainly boreal atlantic |
| 78. | Anarhichas lupus Linnaeus, 1758 | Bottom | Mainly boreal atlantic |
| 79. | Anarhichas minor Olafsen, 1772 | Bottom | Mainly boreal atlantic |

|  | Ammodytidae | Bottom | Bottom |
| :--- | :--- | :--- | :--- |
| 80. | Ammodytes marinus Raitt, 1934 |  | Mainly boreal european |
| 81. | Ammodytes tobianus Linnaeus, 1758 <br> Scombridae | Neritopelagic | Boreal european |
| 82. | Scomber scombrus Linnaeus, 1758 <br> Pleuronectiformes | Southboreal atlantic |  |
|  | Pleuronectidae | Bottom |  |
| 83. | Glyptocephalus cynoglossus (Linnaeus, 1758) | Bottom | Bottom |
| 84. | Hippoglossoides platessoides (Fabricius, 1780) | Bottom | Mainly boreal atlantic |
| 85. | Hippoglossus hippoglossus (Linnaeus, 1758) | Bottom | Mainly boreal european |
| 86. | Limanda limanda (Linnaeus, 1758) | Bottom | Mainly boreal european |
| 87. | Microstomus kitt (Walbaum, 1792) | Bottom | Boreal european |
| 88. | Pleuronectes platessa Linnaeus, 1758 |  | Mainly boreal european |
| 89. | Reinhardtius hippoglossoides (Walbaum, 1792) | Mainly boreal atlantic |  |
