## Preface

Annual catch quotas and other regulations of the Barents Sea fisheries are set through negotiations between Norway and Russia. Assessment of the state of the stocks and quota advices are given by the International Council for the Exploration of the Sea (ICES). Their work is based on survey results and international landings statistics. The results from the demersal fish winter surveys in the Barents Sea are an important source of information for the annual stock assessment.

The development of the survey started in the early 1970s and focused on acoustic measurements of cod and haddock. Since 1981 it has been designed to produce both acoustic and swept area estimates of fish abundance. Some development has taken place since then, both in area coverage and in methodology. The development is described in detail by Jakobsen et al. (1997), Johannesen et al. (2009) and Appendix 2. At present the survey provides the main data input for a number of projects at the Institute of Marine Research, Bergen:

- monitoring abundance of the Barents Sea demersal fish stocks
- mapping fish distribution in relation to climate and prey abundance
- monitoring food consumption and growth
- estimating predation mortality caused by cod

This report presents the main results from the surveys in January-March 2013-2014. The surveys were performed with the Norwegian research vessels "Johan Hjort" and "Helmer Hanssen" and the Russian research vessels "Fridtjof Nansen" and "Vilnyus". Annual survey reports since 1981 are listed in Appendix 1, and names of scientific participants are given in Appendix 3.

## 1 Introduction

The Institute of Marine Research (IMR), Bergen, has performed acoustic measurements of demersal fish in the Barents Sea since 1976. Since 1981 a bottom trawl survey has been combined with the acoustic survey. Typical effort of the combined survey has been 10-14 vessel-weeks, and about 350 bottom trawl hauls have been made each year. Most years three vessels have participated from about 1 February to 15 March.

The purpose of the investigations is:

- Obtain acoustic abundance indices by length and age for cod, haddock and redfish
- Obtain swept area abundance indices by length (and age) for cod, haddock, redfish and Greenland halibut
- Map the geographical distribution of those fish stocks
- Estimate length, weight and maturity at age for those stocks
- Collect and analyse stomach samples from cod, for estimating predation by cod
- Map the distribution of maturing/prespawning capelin

Data and results from the survey are used both in the ICES stock assessments and by several research projects at IMR and PINRO.

From 1981 to 1992 the survey area was fixed (strata 1-12, main areas ABCD in Fig. 2.1). Due to warmer climate and increasing stock size in the early 1990s, the cod distribution area increased. Consequently, in 1993 the survey area was extended to the north and east (strata 123, main areas D'ES in Fig. 2.1) in order to obtain a more complete coverage of the younger age groups of cod, and since then the survey has aimed at covering the whole cod distribution area in open water. For the same reason the survey area was extended further northwards in the western part in 2014 (strata 24-26 in Fig. 2.1). In most years since 1997 Norwegian research vessels have had limited access to the Russian EEZ, and in 1997, 1998 and 2007 the vessels were not allowed to work in the Russian EEZ. In 1999 the coverage was partly limited by a rather unusually wide ice-extension. Since 2001, except in 2006 and 2007, Russian research vessels have participated in the survey and the coverage has been better, but for various reasons not complete in most years. In 2008-2014 Norwegian vessels had access to major parts of the Russian EEZ. The coverage was more complete in these years, especially in 2008, 2011 and 2014. In 2009, 2010, 2012 and 2013 the coverage in eastern areas was more limited due to strict rules regarding handling of the catch, bad weather or vessel problems. Table 3.6 summarizes degree of coverage and main reasons for incomplete coverage in the Barents Sea winter 1981-2014.

## 2 Methods

### 2.1 Acoustic measurements

The method is explained by Dalen and Smedstad (1979, 1983), Dalen and Nakken (1983), MacLennan and Simmonds (1991) and Jakobsen et al. (1997). The acoustic equipment has been continuously improved. Since the early 1990s Simrad EK500 echo sounder and Bergen Echo Integrator (BEI, Knudsen 1990) have been used. The Simrad ER60 echo sounder and the Large Scale Survey System (LSSS, Korneliussen et al. 2006) has replaced the EK500 and BEI; on R/V "Johan Hjort" since the 2005 survey and on R/V "Helmer Hanssen" since the 2008 survey. On the Russian vessels EK 500 was used from 2000 to 2004 and ER60 since 2005.

In the mid 1990s the echo sounder transducers were moved from the hull to a retractable centreboard, on R/V "Johan Hjort" since the 1994 survey and on R/V "Jan Mayen" since the 2008 survey. This latter change has largely reduced the signal loss due to air bubbles in the close to surface layer. None of the Russian vessels have retractable centreboards.

On the Norwegian vessels acoustic backscattering values $\left(\mathrm{s}_{\mathrm{A}}\right)$ are stored at high resolution in LSSS. After scrutinizing and allocating the values to species or species groups, the values are stored with 10 m vertical resolution and 1 nautical mile (NM) horizontal resolution. The procedure for allocation by species is based on:

- composition in trawl catches (pelagic and demersal hauls)
- the appearance of the echo recordings
- inspection of target strength distributions
- inspection of target frequency responses

For each trawl catch the relative $\mathrm{s}_{\mathrm{A}}$-contribution from each species is calculated (Korsbrekke 1996) and used as a guideline for the allocation. In these calculations the fish length dependent catching efficiency of cod and haddock in the bottom trawl (Aglen and Nakken 1997) is taken into account. If the trawl catch gives the true composition of the species contributing to the observed $\mathrm{s}_{\mathrm{A}}$ value, those catch-based $\mathrm{s}_{\mathrm{A}}$ - proportions could be used directly for the allocation. In the scrutinizing process the scientists have to evaluate to what extent these catch-based $\mathrm{s}_{\mathrm{A}}$-proportions are reasonable, or if they should be modified on the basis of knowledge about the fish behaviour and the catching performance of the gear.

## Estimation procedures

The area is divided into rectangles of $1 / 2^{\circ}$ latitude and $1^{\circ}$ longitude. For each rectangle and each species an arithmetic mean $\mathrm{s}_{\mathrm{A}}$ is calculated for the demersal zone (less than 10 m above bottom) and the pelagic zone (more than 10 m above bottom). Each of those acoustic densities by rectangle are then converted to fish densities by the equation:

$$
\begin{equation*}
\bar{\rho}_{A}=\frac{\bar{s}_{A}}{\bar{\sigma}_{A}} \tag{1}
\end{equation*}
$$

$\bar{\rho}_{A}$ is average fish density (number of fish / square NM) by rectangle
$\bar{s}_{A}$ is average acoustic density (square $\mathrm{m} /$ square NM) by rectangle
$\bar{\sigma}_{A}$ is average backscattering cross-section (square NM) by rectangle

For cod, haddock and redfish the backscattering cross-section ( $\sigma$ ), target strength (TS) and fish length ( L cm ) is related by the equation (Foote, 1987):

$$
\begin{equation*}
\mathrm{TS}=10 \cdot \log \left(\frac{\sigma}{4 \pi}\right)=20 \cdot \log (L)-68 \tag{2}
\end{equation*}
$$

Indices for the period 1981-1992 have been recalculated (Aglen and Nakken 1997) taking account of:

- changed target strength function
- changed bottom trawl gear (Godø and Sunnanå 1992)
- size dependant catching efficiency for cod and haddock (Dickson 1993a,b)

In 1999 the indices for cod and haddock were revised and some errors in the time series were discovered and corrected (Bogstad et al. 1999).

Combining equations 1 and 2 gives

$$
\begin{equation*}
\bar{\rho}_{A}=5.021 \cdot 10^{5} \cdot \bar{s}_{A} / \bar{L}^{2} \tag{3}
\end{equation*}
$$

$\bar{L}^{2}$ is average squared fish length by rectangle and by depth channels (i.e., pelagic and bottom).

As a basis for estimating $\bar{L}^{2}$ trawl catches considered to be representative for each rectangle and depth zone are selected. This is a partly subjective process, and in some cases catches from neighbouring rectangles are used. Only bottom trawl catches are used for the demersal zone, while both pelagic and bottom trawl catches are applied to the pelagic zone. Length frequency distributions by 1 cm length groups form the basis for calculating mean squared length. The bottom trawl catches are normalised to 1 NM towing distance and adjusted for length dependant fishing efficiency (Aglen and Nakken 1997, see below). Length distributions from pelagic catches are applied unmodified. Since 2001 the post processing program BEAM has been used for working out the acoustic estimates. This program provides an automatic allocation of trawl samples to strata (rectangles). The automatic allocation is modified by the user when considered necessary.

Let $f_{i}$ be the (adjusted) catch by length group $i$ and let $L_{i}$ be the midpoint ( cm ) of the length interval $i$. Then:

$$
\begin{equation*}
\bar{L}^{2}=\frac{\sum_{i=i_{\min }}^{i_{\max }} f_{i} \cdot L_{i}^{2}}{\sum_{i=i_{\min }}^{i_{\max }} f_{i}} \tag{4}
\end{equation*}
$$

For each species the total density ( $\bar{\rho}_{A}$ ) by rectangle and depth zone is now calculated by equation (3). This total density is then split on length groups according to the estimated length distribution. Next, these densities are converted to abundance by multiplying with the area of the rectangle. The abundance by rectangle is then summed for defined main areas (Figure 2.1). Estimates by length are converted to estimates by age using an age length key for each main area. The total biomass is estimated by multiplying the numbers at age by weight at age from the swept area estimates (see section 2.3).

### 2.2 Swept area measurements

All vessels were equipped with the standard research bottom trawl Campelen 1800 shrimp trawl with 80 mm (stretched) mesh size in the front. Prior to 1994 a cod-end with $35-40 \mathrm{~mm}$ (stretched) mesh size and a cover net with 70 mm mesh size were used. Since this mesh size may lead to considerable escapement of 1 year old cod, the cod-ends were in 1994 replaced by cod- ends with 22 mm mesh size. At present a cover net with 116 mm meshes is mostly used.

The trawl is now equipped with a rockhopper ground gear (Engås and Godø 1989). Until and including 1988 a bobbins gear was used, and the cod and haddock indices from the time period 1981-1988 have since been recalculated to 'rockhopper indices' and adjusted for length dependent fishing efficiency and/or sweep width (Godø and Sunnanå 1992, Aglen and Nakken 1997). The sweep wire length is 40 m , plus 12 m wire for connection to the doors.

In the Norwegian shrimp survey (Aschan and Sunnanå 1997) the Campelen trawl has been rigged with some extra floats ( 45 along the ground rope and 18 along the under belly and trunk, all with 20 mm diameter) to reduce problems on very soft bottom. This rigging has been referred to as "Tromsø rigging". When the shrimp survey was terminated 2004 and later merged with the Ecosystem survey in 2005, improved shrimp data were also requested from the winter survey, and the "Tromsø rigging" was used in parts of the shrimp areas in 2004 (11 stations) and 2005 ( 9 stations). Since 2006 the "Troms $\varnothing$ rigging" has been used for nearly all bottom trawl stations taken by Norwegian vessels in the winter survey.

Vaco doors ( $6 \mathrm{~m}^{2}, 1500 \mathrm{~kg}$ ), were previously standard trawl doors on board the Norwegian research vessels. On the Russian vessels and hired vessels V-type doors (ca $7 \mathrm{~m}^{2}$ ) have been used. In 2004, R/V "Johan Hjort" changed to a V-type door (Steinshamn W-9, 7.1m², 2050 kg ), the same type as used on the Russian research vessels. In 2010 the V-doors were replaced
by 125 " Thyborøn trawl doors. R/V "Helmer Hanssen" has used Thyborøn trawl doors since the 2008 survey.
In order to achieve constant sampling width of a trawl haul independent of e.g. depth and wire length, a $10-14 \mathrm{~m}$ rope "locks" the distance between the trawl wires $80-150 \mathrm{~m}$ in front of the trawl doors on the Norwegian vessels. This is called "strapping". The distance between the trawl doors is then in most hauls restricted to the range 48-52 m regardless of depth (Engå and Ona 1993, Engås 1995). Strapping was first attempted in the 1993 survey on board one vessel, in 1994 it was used on every third haul and in 1995-1997 on every second haul on all vessels. Since 1998 it has been used on all hauls when weather conditions permitted. Strapping is not applied on the Russians vessels, but the normal distance between the doors is about 50 m (D. Prozorkevich, pers. comm.).

Standard tow duration is now 15 minutes (until 1985 the tow duration was 60 min . and from 1986 to 201030 min ). Trawl performance is constantly monitored by Scanmar trawl sensors, i.e., distance between the doors, vertical opening of the trawl and bottom contact control. In 2005-2008 sensors monitoring the roll and pitch angle of the doors were used due to problems with the Steinshamn W-9 doors. The data is logged on files, but have so far not been used for further evaluation of the quality of the trawl hauls.

The positions of the trawl stations are pre-defined. When the swept area investigations started in 1981 the survey area was divided into four main areas (A, B, C and D, Fig 2.1) and 35 strata.

Figure 2.1. Strata (1-23) and main areas (A,B,C,D,D',E and S) used for swept area estimations. The main areas are also used for acoustic estimation. Additional strata (24-26, main area N) covered in 2014, but not included in the estimations.

During the first years the number of trawl stations in each stratum was set based on expected fish distribution in order to reduce the variance, i.e., more hauls in strata where high and variable fish densities were expected to occur. During the 1990s trawl stations have been spread out more evenly, yet the distance between stations in the most important cod strata is shorter ( 16 or 20 NM ) compared to the less important strata ( 24,30 or 32 NM ). During the 1990s considerable amounts of young cod were distributed outside the initial four main areas, and in 1993 the investigated area was therefore enlarged by areas D', E, and the ice-free part of Svalbard (S) (Fig. 2.1 and Table 3.5), 28 strata altogether. In the 1993-1995 survey reports, the Svalbard area was included in A' and the western (west of $30^{\circ} \mathrm{E}$ ) part of area E. Since 1996 a revised strata system with 23 strata has been used (Figure 2.1). The main reason for reducing the number of strata was the need for a sufficient number of trawl stations in each stratum to get reliable estimates of density and variance. In later years a few pre-defined trawl stations have been performed north of the strata system due to increased abundance of cod in these areas, and in 2014 the investigated area was enlarged by three new strata in northwest, 24-26 (main area N, Fig. 2.1). However, the data are so far not included in the estimation of standard abundance indices.

## Swept area fish density estimation

Swept area fish density estimates $\left(\rho_{s, l}\right)$ by species ( $s$ ) and length ( $l$ ) were estimated for each bottom trawl haul by the equation:

$$
\rho_{\mathrm{s}, l}=\frac{f_{\mathrm{s}, l}}{a_{\mathrm{s}, l}}
$$

$\rho_{s, l} \quad$ number of fish of length $l$ per n.m. ${ }^{2}$ observed on trawl station $s$
$f_{s, l}$ estimated frequency of length $l$
$a_{s, l} \quad$ swept area:

$$
a_{s, l}=\frac{d_{s} \cdot E W_{l}}{1852}
$$

$d_{s}$ towed distance (nm)
$E W_{l}$ length dependent effective fishing width:

$$
\begin{aligned}
& E W_{l}=\alpha \cdot l^{\beta} \text { for } l_{\min }<l<l_{\max } \\
& E W_{l}=E W_{l_{\min }}=\alpha \cdot l_{\min }^{\beta} \text { for } l \leq l_{\min } \\
& E W_{l}=E W_{l_{\max }}=\alpha \cdot l_{\max }^{\beta} \text { for } l \geq l_{\max }
\end{aligned}
$$

The parameters are given in the text table below:

| Species | $\boldsymbol{\alpha}$ | $\boldsymbol{\beta}$ | $\boldsymbol{I}_{\min }$ | $\boldsymbol{I}_{\max }$ |
| :--- | :---: | :---: | :---: | :---: |
| Cod | 5.91 | 0.43 | 15 cm | 62 cm |
| Haddock | 2.08 | 0.75 | 15 cm | 48 cm |

The fishing width was previously fixed to $25 \mathrm{~m}=0.0135 \mathrm{~nm}$. Based on Dickson (1993a,b), length dependent effective fishing width for cod and haddock was included in the calculations in 1995 (Korsbrekke et al., 1995). Aglen and Nakken (1997) have adjusted both the acoustic and swept area time series back to 1981 for this length dependency based on mean-length-atage information. In 1999, the swept area 1983-1995 time series was recalculated for cod and haddock using the new area and strata divisions (Bogstad et al. 1999).

For redfish, Greenland halibut and other species, a fishing width of 25 m was applied, independent of fish length.

For each station, s, observations of fish density by length ( $\rho_{\mathrm{s}, l}$ ) is summed in 5 cm lengthgroups. Stratified indices by length-group and stratum will then be:

$$
L_{p, l}=\frac{A_{p}}{S_{p}} \cdot \sum_{\text {sin stratum } p} \rho_{s, l}
$$

$L_{p, l}$ index, stratum $p$, length-group $l$
$A_{p}$ area (n.m. ${ }^{2}$ ) of stratum $p$ (or the part of the stratum covered by the survey)
$S_{p}$ number of trawl stations in stratum $p$

The coverage of the most northern and most eastern strata differs from year to year. The areas of these strata are therefore calculated according to the coverage each year (Table 3.5). Indices are estimated for each stratum within the main areas A, B, C, D, D', E and S. Total number of fish in each 5 cm length group in each main area is estimated by adding the indices of all strata within the area. Total number of fish at age is estimated by using an age-length key constructed for each main area. Total indices on length and age are estimated adding the values for all main areas.

### 2.3 Sampling of catch and age-length keys.

Sorting, weighing, measuring and sampling of the catch are done according to instructions given in Mjanger et al. (2014). Since 1999 all data except age are recorded electronically by Scantrol Fishmeter measuring board, connected to stabilized scales. The whole catch or a representative sub sample of most species was length measured on each station.

At each trawl station age (otoliths) and stomach were sampled from one cod per 5 cm lengthgroup. In 2007-2009, all cod above 80 cm were sampled, and in 2010 all above 90 cm , limited to 10 per station. The stomach samples were frozen and analysed after the survey. Haddock
otoliths were sampled from one specimen per 5 cm length-group. Regarding the redfish species, Sebastes norvegicus and S. mentella, otoliths for age determination were sampled from two fish in every 5 cm length-group on every station. Greenland halibut were sorted by sex before length measurement and otolith sampling. From this species otoliths were collected from 5 fish per 5 cm length group for each sex on all stations. Table 3.4 gives an account of the sampled material.

An age-length key is constructed for each main area. All age samples are included and weighted according to:

$$
w_{p, l}=\frac{L_{p, l}}{n_{p, l}}
$$

$w_{p, l}$ - weighting factor
$L_{p, l}$ - swept area index of number fish in length-group lin stratum $p$
$n_{p, l}$ - number of age samples in length-group $l$ and stratum $p$

Fractions are estimated according to:

$$
P_{a}^{(l)}=\frac{\sum_{p} n_{p, a, l} \cdot w_{p, l}}{\sum_{p} n_{p, l} \cdot w_{p, l}}
$$

$p_{a}^{(l)} \quad$ - weighted fraction of age $a$ in length-group $l$ and stratum $p$
$n_{p, a, l}$ - number of age samples of age $a$ in length-group $l$ and stratum $p$

Number of fish by age is then estimated following the equation:

$$
N_{a}=\sum_{p} \sum_{l} L_{p, l} \cdot P_{a}^{(l)}
$$

Mean length and -weight by age is then estimated according to (only shown for weight):

$$
W_{a}=\frac{\sum_{p} \sum_{l} \sum_{j} W_{a, p, l, j} \cdot w_{p, l}}{\sum_{p} \sum_{l} \sum_{j} w_{p, l}}
$$

$W_{a, p, l, j}$ - weight of sample $j$ in length-group $l$, stratum $p$ and age $a$

## 3 Survey operation and material

Table 3.1 presents the vessels participating in the survey in 2013 - 2014 and IMR trawl station series numbers. Catch data and biological samples from the Russian vessels were converted to the IMR SPD-format. The acoustic data from the Russian vessels was reported to IMR as allocated values by species at 5 nm intervals, split on a bottom layer ( $<10 \mathrm{~m}$ from bottom) and a pelagic layer (>10m above bottom).

Table 3.1. Norwegian and Russian vessel participation by time period and Norwegian trawl station series numbers by vessel for the winter surveys 2013-2014.

|  | Year |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
|  | 2013 |  |  | 2014 |
| Vessel | Period | Series no. | Period | Series no. |
| Johan Hjort | $01.02-14.03$ | $70001-70187$ | $31.01-11.03$ | $70001-70196$ |
| Helmer Hanssen |  |  | $22.01-02.03$ | $70301-70490$ |
| Fridtjof Nansen | $08.02-02.03$ | $00001-00128$ |  | $0001-17.02$ |
| Vilnyus |  |  | 00113 |  |

Table 3.2 presents the number of swept area trawl stations, other bottom trawl stations and pelagic trawl stations taken in the different main areas. For the calculation of swept area indices, only the successful pre-defined bottom trawl stations within the strata system were used. The number of stations in the new strata 24-26 are also given. Table 3.3 gives an account of the sampled length- and age material from bottom hauls and pelagic hauls. Figure 3.1 shows survey tracks and trawl stations for each survey in 2013-2014.

Figure 3.1. Survey tracks and all trawl stations in the winter survey 2013-2014. Data source for the monthly ice cover: ftp://sidads.colorado.edu/DATASETS/NOAA/G02135/shapefiles/

Table 3.2. Number of trawl stations by main area in the Barents Sea winter 2013-2014. $\mathrm{B}_{1}=$ swept area bottom trawl (quality $=1$ and condition<3), $\mathrm{B}_{2}=0$ other bottom trawl, $\mathrm{P}=$ pelagic trawl, $\mathrm{N}=$ trawl stations in new strata.

## 4 Hydrography

The standard hydrographical sections "Fugløya-Bjørnøya" and "Vardø-Nord" are taken during the later part of the surveys. Figure 4.1 shows the observed mean temperature at 50200 m depth for the period 1977-2014. Both time series show an increasing trend. The increases in temperatures are approximately 0.44 ("Fugløya-Bjørnøya") and 0.51 ("VardøNord") ${ }^{\circ} \mathrm{C}$ per decade. Unfortunately, the time series have some missing values.

Figure 4.1. Mean temperatures in 50-200 m depth in 1977-2014.
A) "Fugløya-Bjørnøya" in March, B) "Vardø-Nord" in March.

## 5 Total echo abundance of cod and haddock

Table 5.1 presents the time series of total echo abundance (echo density multiplied by area) of cod and haddock in the investigated areas. Since 1993 the acoustic values have been split between the two species during the scrutinizing. The values for cod have showed an increasing trend since the mid 2000s, with a peak in 2013. The values for haddock increased gradually from the end of the 1990s to 2009, and have decreased somewhat in the later years. The fraction of the total echo abundance recorded in the bottom layer has been somewhat lower in later years for cod compared to the mid 2000s. For haddock this fraction is lower than for cod and more stable over the time series.

Figures 5.1 and 5.2 present the distribution of total echo abundance by estimation rectangles in 2013-2014 for cod and haddock, respectively. The 2014 maps show distributions north of the swept area strata, probably extending even further north.

Table 5.1. Cod and haddock. Total echo abundance and echo abundance in the 10 m layer above the bottom in the Barents Sea winter 1981-2014 ( $\mathrm{m}^{2}$ reflecting surface $\cdot 10^{-3}$ ). 1981-1992 includes only mainly areas A, B, C and D.

Figure 5.2. HADDOCK. Distribution of total echo abundance winter 2013-2014. Unit is $\mathrm{s}_{\mathrm{A}}$ per square nautical mile ( $\mathrm{m}^{2} / \mathrm{n}$.mile ${ }^{2}$ ). Swept area strata and main areas (thick line) in red.

## 6 Distribution and abundance of cod

### 6.1 Acoustic estimation

Surveys in the Barents Sea at this time of the year mainly cover the immature part of the cod stock. Most of the mature cod (age 7 and older) have started on their spawning migration southwards out of the investigated area, and are therefore covered to a lesser extent. There are indications that a higher proportion than normal spawned along Finnmark in some of the recent years, e.g. 2004-2006. Thereby a higher proportion of the spawners might have been covered by the survey these years.

Table 6.1 shows the acoustic indices for each age group by main areas in 2013-2014. The time series (1981-2014) is presented in Table 6.2. The estimates have been variable and increasing in later years, with a peak in 2013, and this may partly be explained by variable and not complete coverage of the distribution area towards north and east in several years. As cod grow older, their distribution shifts more south-westerly during winter, and they it so to say "grows" into the incomplete survey. This is especially evident for the strong 2004 and 2005 year-classes, which as 6-7 year olds stand out as the strongest in the time series. Of more recent year-classes the 2011 year-class seems to be strong.

Table 6.1. COD. Acoustic abundance for the main areas of the Barents Sea winter 2013-2014 (numbers in millions).

Table 6.2. COD. Abundance indices from acoustic surveys in the Barents Sea winter 1981-2014 (numbers in millions). 1981-1992 includes only main areas A, B C and D. Observations outside main areas A-S not included.

[^1]
### 6.2 Swept area estimation

Figures 6.1-6.4 show the geographic distribution of bottom trawl catch rates (number of fish per $\mathrm{NM}^{2}$, for cod size groups $\leq 19 \mathrm{~cm}, 20-34 \mathrm{~cm}, 35-49 \mathrm{~cm}$ and $\geq 50 \mathrm{~cm}$. As in previous years, a high proportion of the smallest cod (less than 35 cm ) were found in the eastern part of the survey area within the Russian EEZ and near the northern borders of the standard strata system (strata 1-23). In 2014 a higher proportion of $\operatorname{cod} \leq 19 \mathrm{~cm}$ were found in the extended survey area (strata 24-26) than in the rest of the survey area (Table 6.3). These size groups have probably been largely underestimated in earlier years. Mehl et al. (2013) found that since 2009 more of the largest cod had been found in the north-western part of the survey area (main area S), and this trend is confirmed by the 2013 and 2014 estimates.

Figure 6.1. COD $\leq 19 \mathrm{~cm}$. Distribution in valid bottom trawl catches winter 2013-2014 (number per $\mathrm{nm}^{2}$ ). Zero catches are indicated by black points.

Figure 6.2. COD 20-34 cm. Distribution in valid bottom trawl catches winter 2013-2014 (number per $\mathrm{nm}^{2}$ ). Zero catches are indicated by black points.

Figure 6.3. COD 35-49 cm. Distribution in valid bottom trawl catches winter 2013-2014 (number per $\mathrm{nm}^{2}$ ). Zero catches are indicated by black points.

Figure 6.4. $C O D \geq 50 \mathrm{~cm}$. Distribution in valid bottom trawl catches winter 2013-2014 (number per $\mathrm{nm}^{2}$ ). Zero catches are indicated by black points.

Table 6.3 presents the distribution of the indices by main areas and age and the whole time series (1981-2014) is shown in Table 6.4. Also the bottom trawl indices have fluctuated somewhat due to the same reasons as for the acoustic indices, and the 2004 and 2005 yearclasses at the moment stand out as the strongest in the time series. Both the 2009 and 2011 year-classes seemed to be strong as 1 -year olds, but the 2009 year-class was reduced to below average level at age 3. A considerable amount of cod was found in the extended survey area (Table 6.3), on average over all age groups about $76 \%$ of the amount found in the standard survey area by numbers and about $15 \%$ by biomass.

Table 6.3. COD. Abundance indices from bottom trawl hauls for main areas of the Barents Sea winter 20132014 (numbers in millions.).

### 6.3 Growth and survey mortalities

Tables 6.5 and 6.6 present the time series for mean length (1981-2014) and mean weight (1983-2014) at age for the entire standard area. Weights and lengths at age were fairly low in the period 1995-2000, but increased somewhat in 2001. Since then there has been moderate fluctuations, but with a slight decreasing trend for older fish (6+) in later year. The same pattern is reflected in the annual weight increments (Table 6.7).

Table 6.8 gives the time series of survey based mortalities (log ratios between survey indices of the same year class in two successive years) since 1993. These mortalities are influenced by natural and fishing mortality, age reading errors, and the catchability and availability (coverage) at age for the survey. In the period 1993-1999 there was an increasing trend in the survey mortalities. The trend appears most consistent for the age groups 3-7 in the swept area estimates. Most later surveys show lower mortalities, but there are some fluctuations for the same reasons as mentioned for the acoustic and swept area indices. Presumably the mortality of the youngest age groups (ages 1-3) is mainly caused by predation, while for the older age groups it is mainly caused by the fishery. Before 2001 the survey mortalities for age 4 and older were well above the mortalities estimated in the ICES assessment. Decreasing survey catchability at increasing age could be one reason for this. Another possible reason could be that the assessment does not include all sources of mortality, like discards, unreported catches, or poorly quantified predation. The low survey mortalities in the most recent years, even with "impossible" negative values, could partly be caused by fish gradually "growing into" the covered area at increasing age. The observed mortality rates in the acoustic investigations have been more variable. This might be caused by changes in fish behaviour and how available the fish is for acoustic registration.

Table 6.5. COD. Length (cm) at age in the Barents Sea from the investigations winter 1981-2014. Observations outside main areas A-S not included.

| Year | Age |  |  |  |  |  |  |  |

### 6.4 Stomach sampling

Since 1984, cod stomachs have been sampled regularly during the winter survey. The sampling strategy has generally been the same as that for sampling otoliths. Stomach have been frozen onboard and analysed in the laboratory, except for the period 1994-2000, when some of the stomachs were analysed onboard and only the main prey categories were identified. For details about the sampling methodology and the Norwegian-Russian cooperation on diet investigations in the Barents Sea, see Mehl and Yaragina (1992) and Dolgov et al. (2007).

The number of stations and stomachs sampled as well as the proportion of empty stomachs and the mean stomach fullness index (SFI, see below) for each of 4 size groups ( $\leq 19 \mathrm{~cm}, 20$ $34 \mathrm{~cm}, 35-49 \mathrm{~cm}, \geq 50 \mathrm{~cm}$ ) is given in Table 6.9. Table 6.10-6.13 show the mean diet composition by prey species/groups by year for each size group. Note that in the years 19942000, blue whiting, long rough dab and Norway pout were included in the category 'other fish' when stomachs were analysed onboard.

The stomach fullness index is calculated as $\mathrm{SFI}_{\mathrm{i}}=100 * \mathrm{LWS}_{\mathrm{i}} / \mathrm{W}_{\mathrm{i}}$, where $\mathrm{WS}_{\mathrm{i}}$ is the weight $(\mathrm{g})$ of the stomach of fish $i$, and $\mathrm{W}_{\mathrm{i}}$ is the weight ( g ) of fish i. For 1987 SFI has not been calculated, because very few fish were weighed that year due to technical problems. The distribution on prey groups has been adjusted by distributing the unidentified component of the diet proportionally among the various components, taking into account the level of identification.

The geographical distribution of stomach fullness and prey composition divided into three prey categories (capelin, other fish, other food) by length group and year is shown in Figures 6.5-6.6. The proportion of empty stomachs is largest for the smallest fish (Table 6.9), a pattern seen for all years. Capelin is the dominating prey for cod $\geq 20 \mathrm{~cm}$ (Tables 6.11-6.13), while krill dominates for the smallest cod (Table 6.10). However, in many years capelin is also an important prey for the smallest cod. The diet composition in 2013-2014 was generally similar to that in the period 2008-2012. The stomach fullness index SFI was generally lower than in the period 2008-2012. In particular, the SFI for the largest fish ( $>=50 \mathrm{~cm}$ ) in 2014 was the lowest since 1998, and the proportion of capelin in the diet of this size group in 2014 was the lowest since 2009. Reasons for this could be both that the 2014 survey also covered the area west of Svalbard, where capelin is scarce, and also that the proportion of the fish >= 50 cm which is mature is higher than in previous years. Mature fish probably feeds less intensively than immature fish at this time of the year.

The highest stomach fullness is found in the south-eastern part of the survey area and along the coast of Norway and Russia. However, there are also in most years some stations with high stomach fullness close to the northern limit of the survey area. In the western part of the Barents Sea and west of Svalbard the SFI is generally low.
Table 6.9. Number of stations and stomach sampled, \% empty stomachs, and mean stomach fullness by length group in the Barents Sea winter 1984-2014.

|  |  | Stomachs |  |  |  | \% empty |  |  |  | Stomach fullness |  |  |  |

Figure 6.5. Stomach fullness and diet composition by cod size group in 2013 , by $1^{\circ} \times 2^{\circ}$ areas. Prey are grouped into the categories capelin, other fish and other prey. The size of the circles indicate the stomach fullness.

Figure 6.6. Stomach fullness and diet composition by cod size group in 2014 , by $1^{\circ} \times 2^{\circ}$ areas. Prey are grouped into the categories capelin, other fish and other prey. The size of the circles indicate the stomach fullness.

## 7 Distribution and abundance of haddock

### 7.1 Acoustic estimation

Like for cod it is expected that the survey best covers the immature part of the stock. At this time of the year a large proportion of the mature haddock (age 6 and older) are on its spawning migration south-westwards out of the investigated area. In some earlier years, e.g. 2004 and 2005, concentrations of mature haddock have been observed pelagic rather far above bottom along the shelf edge. These concentrations are poorly covered by the bottom trawl sampling.

There are indications that the distribution of age groups 1 and 2 in some years are concentrated in coastal areas not well covered by the survey. This occurred in the late 1990s and will have strongest effect on poor year-classes. In the later surveys small haddock has been widely distributed, and the strong year-classes have been found unusually far to the north. This might be caused by favourably hydrographic conditions and/or density-dependent mechanisms. However, it is difficult to separate the two factors. Favourable hydrographic conditions may lead to better distribution of larvae and thus better survival. On the other hand, high densities of juveniles may cause delayed settlement and more active movement in search of prey.

Table 7.1 shows the acoustic abundance indices by age within the main areas. As in most of the previous years the highest abundance was observed in main area D. The time series (19812014) are presented in Table 7.2. The strong 2004-2006 year-classes can be followed through the time series and still have a strong contribution to the total abundance. In later years, the 2009, 2011 and 2013 year-classes seem to be fairly strong.

Table 7.1. HADDOCK. Acoustic abundance indices for the main areas of the Barents Sea winter 2013-2014 (numbers in millions).

### 7.2 Swept area estimation

Figures 7.1-7.4 show the geographic distribution of bottom trawl catch rates (number of fish per $\mathrm{NM}^{2}$ ) for haddock size groups $\leq 19 \mathrm{~cm}, 20-34 \mathrm{~cm}, 35-49 \mathrm{~cm}$ and $\geq 50 \mathrm{~cm}$. Like in previous years (Mehl et al. 2013), the distribution extends further to the north and to the east than what was usual in the 1990s. To a certain degree, one can follow the high densities through the size groups, especially the northern and eastern distributions. This indicates that the distribution is more cohort-dependent than age-dependent, and it may be more appropriate to use cohort as scaling covariate rather than age, when indices are adjusted for poor coverage.

Table 7.3 presents the indices for each age group by main areas. The time series (1981-2014) are shown in Table 7.4. As with the acoustic indices, the strong 2004-2006 year-classes dominates bottom trawl indices. Overall, this survey tracks both strong and poor year-classes fairly well. In later years, the 2009, 2011 and 2013 year-classes are stronger than the 2007, 2008, 2010 and 2012 year-classes.

Compared to cod a much lower proportion of haddock was found in the extended survey area (Table 6.3), on average over all age groups about $10 \%$ of the amount found in the standard survey area by numbers and about $6 \%$ by biomass (Table 7.3).

Figure 7.1. HADDOCK $\leq 19 \mathrm{~cm}$. Distribution in valid bottom trawl catches winter 2013-2014 (number per $\mathrm{nm}^{2}$ ). Zero catches are indicated by black points.

Figure 7.2. HADDOCK 20-34 cm. Distribution in valid bottom trawl catches winter 2013-2014 (number per $\mathrm{nm}^{2}$ ). Zero catches are indicated by black points.

Figure 7.3. HADDOCK $35-49 \mathrm{~cm}$. Distribution in valid bottom trawl catches winter 2013-2014 (number per $\mathrm{nm}^{2}$ ). Zero catches are indicated by black points.

Figure 7.4. HADDOCK $\geq 50 \mathrm{~cm}$. Distribution in valid bottom trawl catches winter 2013-2014 (number per $\mathrm{nm}^{2}$ ). Zero catches are indicated by black points.

Table 7.3. HADDOCK. Abundance indices from bottom trawl hauls for main areas of the Barents Sea winter 2013-2014 (numbers in millions).

### 7.3 Growth and survey mortalities

Tables 7.5 and 7.6 present the time series for mean length (1983-2014) and mean weight (1983-2014) at age for the entire standard area. Length estimates have been variable with no specific trends in the latest years. However, the variation is less than what it has been in earlier periods. Weight estimates also show less variation in later years, however there is a slight trend of decreasing weights of 4 years and older haddock for the last decade. Annual weight increments are shown in Table 7.7, these are highly variable and show no trends.

Table 7.5. HADDOCK. Length (cm) at age in the Barents Sea from the investigations winter 1983 - 2014. Observations outside main areas A-S not included.

Survey mortalities based on the acoustic indices (Table 7.8) have varied between years, and for most age groups there is no obvious trends. However, there are signs of co-variability within years.

Table 7.8. Survey mortality observed for haddock during the winter survey in the Barents Sea for the period 1993-2014.

## 8 Distribution and abundance of redfish

### 8.1 Acoustic estimation

Earlier reports from this survey has presented distribution maps and abundance indices based on acoustic observations of redfish. In recent years blue whiting has dominated the acoustic records in some of the main redfish areas. Due to incomplete pelagic trawl sampling the splitting of acoustic records between blue whiting and redfish has been very uncertain. The uncertainty relates mainly to the redfish, since it only make up a minor proportion of the total value. This has been the case since the 2003 survey, and the acoustic results for redfish are therefore not included in the report.

### 8.2 Swept area estimation

The swept area time series for redfish (Tables $8.1-8.3$ ) are based on catch data from trawls with bobbins gear until 1988 inclusive, and rockhopper gear since 1989. The time series has not been adjusted for this change.

Figure 8.1 shows the geographical distribution of Sebastes norvegicus (Golden redfish) based on the catch rates in bottom trawl. It is mainly distributed south of the Bear Island. In most years the distribution is completely covered except towards northwest. Also S. norvegicus was found in the extended survey area in 2014, mainly west of Spitsbergen (strata 24), on average over all size groups about $34 \%$ of the amount found in the standard survey area by numbers (Table 8.1). Table 8.1 presents the time series (1986-2014) of swept area indices by 5 cm length groups. The indices have remained low since 1999 for all length groups. This indicates that at least the last fifteen year classes are very weak.

The mapping of the distribution of $\boldsymbol{S}$. mentella (Beaked redfish) (Figure 8.2) is not complete west and north of Spitsbergen. However, compared to S. norvegicus a smaller proportion was found in the extended survey area in 2014, only about $7 \%$ of the amount found in the standard survey area by numbers. Table 8.2 presents the time series (1986-2014) of swept area indices for $S$. mentella by 5 cm length groups. A few good year classes were born in 1988-1990 before the recruitment collapse in 1991 and the stock decreased to low levels for about fifteen years. However, these few year classes got enough protection to survive to maturity and since 2007-2008 both recruitment and the number of larger S. mentella has been at a fairly high level.

Figure 8.3 shows the geographical distribution of S. viviparus (Norway redfish / lesser redfish) and Table 8.3 presents the time series (1986-2014) of swept area indices by 5 cm length groups. Almost all S. viviparus are found in area ABCD , and mainly in main area B. The indices are often driven by a few large catches, and since the mid 1990s the indices has most in years been below the average level in the time series 1986-2014. There was a large and unexplained increase in the indices for most size groups from 2013 to 2014. The total index is the highest in the time series back to 1986.

Figure 8.1. Sebastes norvegicus. Distribution in the trawl catches winter 2013-2014 (number per $\mathrm{nm}^{2}$ ). Zero catches are indicated by black points.

Figure 8.2. Sebastes mentella. Distribution in the trawl catches winter 2013-2014 (number per $\mathrm{nm}^{2}$ ). Zero catches are indicated by black points.

Figure 8.3. Sebastes viviparus. Distribution in the trawl catches winter 2013-2014 (number per $\mathrm{nm}^{2}$ ). Zero catches are indicated by black points.

Table 8.1. Sebastes norvegicus. Abundance indices from bottom trawl surveys in the Barents Sea winter 19862014 (numbers in millions). 1986-1992 includes only main areas A, B, C and D. Observations outside main areas A-S not included. Species identification uncertain for fish $<10 \mathrm{~cm}$.

## 9. Distribution and abundance of greenland halibut and long rough dab

### 9.1 Greenland halibut

Figure 9.1 shows the distribution of bottom trawl catch rates of Greenland halibut. The most important distribution areas for the adult fish (depths between 500 and 1000 m along the western slope), are not covered by the survey. Greenland halibut was found in the extended survey area in 2014, on average over all size groups about $24 \%$ of the amount found in the standard survey area by numbers (Table 9.1). The observed distribution pattern in 2013-2014 was similar to those observed in previous years' surveys, i.e., mainly in the Bear Island channel towards the Hopen Deep, with some registrations in deep and cold water further east.

Figure 9.1 GREENLAND HALIBUT. Distribution in the trawl catches winter 2013-2014 (number per nm²). Zero catches are indicated by black points.

The time series of swept area indices by 5 cm length groups for 1990-2014 is presented in Table 9.1. Abundance indices have been low in the whole period, with few signs of improved recruitment in the covered area. However, recruitment from more northern areas has lead to an increase in abundance indices of length groups above 30 cm since about 2005.
Table 9.1. GREENLAND HALIBUT. Abundance indices from the bottom trawl surveys in the Barents Sea winter 1990-2014 (numbers in thousands). 1990-1992 includes only main areas A, B, C and D. Observations outside main areas A-S not included.

### 9.2 Long rough dab

Figure 9.2 shows the geographical distribution of long rough dab based on catch rates in bottom trawl. Like in previous years, long rough dab was caught on almost every station in 2013-2014, also in the extended survey area in 2014. It is more evenly spread over its area of distribution than most of the other reported species. This is also reflected in the low relative standard errors (rse) of the abundance indices (Table 9.2).

There was an increase in abundance until about 2002, since then most abundance indices have been relatively stable (Figures 9.3a-b). The recruitment index has been more variable, with highest values between 2000 and 2006 (Figure 9.3a).

Figure 9.2. LONG ROUGH DAB. Distribution in the trawl catches winter 2013-2014 (number per $\mathrm{nm}^{2}$ ). Zero catches are indicated by black points.

Table 9.2 LONG ROUGH DAB. Abundance (N), recruitment (R), total biomass (B), biomass length (L) $\geq 25 \mathrm{~cm}$ and spawning stock biomass (SSB) indices with relative standard errors (rse) from bottom trawl surveys in the Barents Sea winter 1989-2014 (numbers in millions, biomass in 1000 t). 1989-1992 includes only main areas A, B, C and D. Observations outside main areas A-S not included.

| Year | N | rse(N) | R | rse(R) | B | rse(B) | $\mathrm{B}(\mathrm{L} \geq 25)$ | $\begin{aligned} & \text { rse(B) } \\ & (\mathbf{L} \geq 25) \end{aligned}$ | SSB | $\begin{gathered} \text { rse(SSB } \\ \text { ) } \end{gathered}$ |

## 10 Distribution and abundance of capelin, polar cod and blue whiting

### 10.1 Capelin

Although capelin is primarily a pelagic species, small amounts of capelin are normally caught in the bottom trawl throughout most of the investigated area. In Figure 10.1 catch rates of capelin smaller and larger than 14 cm are shown for each of the winter surveys in 2013-2014. Capelin smaller than 14 cm during this period will mainly comprise the immature stock component, while the larger capelin constitute the prespawning capelin stock. Some few trawl hauls show large capelin catches (numbers exceeding 100000 individuals) and these can probably not be considered representative for the density in the area, because such hauls will either result from hitting a capelin school at the bottom or up in the water column. For this reason, we chose not to present swept-area based indices for capelin in this report.

At this time of the year, mature capelin have started their approach to the spawning areas along the coast of Troms, Finnmark and the Kola peninsula, while immature capelin will normally be found further north and east, in the wintering areas. This is reflected on the maps of capelin distribution, even though some large capelin are always found north of $75^{\circ} \mathrm{N}$, and smaller capelin are found sporadically in near-coastal areas in a couple of years. The geographical coverage of the total capelin stock is incomplete, but the maturing component is probably completely covered.

It has been noted during several surveys that when sampling capelin from demersal and pelagic trawls, the individuals from demersal trawls are normally larger (and older) than those sampled pelagically. This has led to the formulation of a hypothesis saying that larger individuals tend to stay deeper than smaller individuals and some even to take up a demersal life. This hypothesis has not been tested, and during the winter surveys there are probably too few pelagic hauls to study the vertical distribution of capelin in a systematic way.

Figure 10.1. CAPELIN. Distribution in the trawl catches winter 2013-2014 (number per $\mathrm{nm}^{2}$ ). Zero catches are indicated by black points.

### 10.2 Polar cod

Polar cod are not well represented in the trawl hauls conducted during the winter surveys (Figure 10.2). This reflects the more northern and eastern distribution area of this endemic arctic species. During this time of the year, the polar cod is known to be spawning under the ice-covered areas of the Pechora Sea and close to Novaya Semlya. It is not clear whether the concentrations found in open water these years are mature fish either on their way to spawning or from the spawning areas, or this is immature fish.

Figure 10.2 POLAR COD. Distribution in the trawl catches winter 2013-2014 (number per $\mathrm{nm}^{2}$ ). Zero catches are indicated by black points.

### 10.3 Blue whiting

Since 2000 the blue whiting has shown a wider distribution than usual. The echo recordings in 2001 and 2002 indicated unusual high abundance in the Barents Sea, while in 2003 it had decreased somewhat. In the 2004 survey the echo abundance increased again and peaked in 2006. Since then it has decreased considerably. Figure 10.3 shows the geographical distribution of the bottom trawl catch rates of blue whiting in 2013-2014. Since the fish was mainly found pelagically, the bottom trawls do not reflect the real density distribution, but give some indication of the distribution limits. Acoustic observations would better reflect the relative density distribution. The number of pelagic hauls has, however, been too low to properly separate the pelagic recordings. During the years with high abundance of blue whiting, recordings of pelagic redfish, haddock and small cod might have been masked by dense concentrations of blue whiting.

Table 10.3 shows the bottom trawl swept area estimates by 5 cm length groups for the years 2001-2014. High abundance of fish below 20 cm in 2001, 2002, 2004, 2005 and 2012 reflects abundant recruiting (age 1) year classes. These recruits are observed in the survey as larger fish in the following years.

Table 10.3. BLUE WHITING. Abundance indices (swept area estimates) from bottom trawl surveys in the Barents Sea winter 2001-2014 (numbers in millions). Observations outside main areas A-S not included.

## 11 Registrations of other species

During the survey 2007-2014 92 fish taxa were recorded (Table 11.1). These include 4 genera and 88 species belonging to 34 families. Of the 92 , 50 were recorded all years. Distribution maps of all species caught at the winter survey 2007-2012 were presented as a separate report (Wienerroither et al. 2013) similar to the Atlas of the Barents Sea fishes (Wienerroither et al. 2011, based on data from the ecosystem survey). Since the start of the winter survey (1981) the number of fish taxa recorded at the survey has increased mostly due to expansion of the area surveyed and better taxonomic skills and identification keys (Johannesen et al. 2009). During the eight years considered in this report, there was no increasing trend in the number of taxa recorded. Due to dedicated workshops on identification, better identification keys and routines for freezing difficult specimens for later identification on land by taxonomists the fish species identification was good. Still there are some groups that remain problematic, mainly liparids and eelpouts.

Table 11.1. Fish species recorded at the winter survey 2007-2014, all gears included. The number of years each species were recorded is shown and for species not caught all years the capture history ( $1=$ caught and $0=$ not caught) are shown in parenthesis for consecutive years 2007-2014. Some clear misidentifications have been left out and some may be uncertain (see comment).

## 12 SUMMARY

In later years it has again become obvious that not all species and age groups are properly covered in the enlarged survey area, e.g. young age groups of the strong 2004 and 2005 yearclasses of cod. This will have strong implications on both the consistency of the time series and the quality and uncertainty of the whole assessment and management advice. Good coverage of the whole available distribution area is therefore essential. In 2014 the investigated area was enlarged by three new strata in northwest, 24-26 (Fig. 2.1). However, the data are so far not included in the estimation of standard abundance indices.

## Cod

The estimates have been variable and increasing in later years, and this may partly be explained by variable and not complete coverage of the distribution area towards north and east in several years. In 2014 a considerable amount of cod was found in the extended survey area, about $76 \%$ of the amount found in the standard survey area by numbers and about $15 \%$ by biomass. A higher proportion of $\operatorname{cod} \leq 19 \mathrm{~cm}$ were found in the extended survey area than in the rest of the survey area. These size groups have probably been largely underestimated in later years. Since 2009 more of the largest cod have been found in the north-western part of the survey area, and this trend is confirmed by the 2013 and 2014 estimates. The 2004 and 2005 year-classes at the moment stand out as the strongest in the time series. Both the 2009 and 2011 year-classes seemed to be strong as 1 -year olds, but the 2009 year-class was reduced to below average level at age 3 .

## Haddock

Overall, the survey tracks both strong and poor year-classes fairly well. In later years, the 2009, 2011 and 2013 year-classes are stronger than the 2007, 2008, 2010 and 2012 yearclasses. The strong 2004-2006 year-classes have dominated in both the acoustic and bottom trawl indices. Compared to cod a much lower proportion of haddock was found in the extended survey area, about $10 \%$ of the amount found in the standard survey area by numbers and about $6 \%$ by biomass.

## Redfish

Also S. norvegicus was found in the extended survey area in 2014, about $40 \%$ of the amount found in the standard survey area by numbers. The indices have remained low since 1999 for all length groups. This indicates that at least the last fifteen year classes are very weak. A smaller proportion of S. mentella was found in the extended survey area in 2014, only about 7 $\%$ of the amount found in the standard survey area by numbers. Since 2007-2008 both recruitment and the number of larger S. mentella has been at a fairly high level. There was a large and unexplained increase in the indices for most size groups of S. viviparus from 2013 to 2014, and the total index is the highest in the time series back to 1986.

## Greenland halibut

The most important distribution areas for the adult fish are not covered by the survey. Greenland halibut was found in the extended survey area in 2014, on average over all size groups about $24 \%$ of the amount found in the standard survey area by numbers. Recruitment from more northern areas has lead to an increase in abundance indices of length groups above 30 cm since about 2005.

## Long rough dab

Like in previous years, long rough dab was caught on almost every station in 2013-2014, also in the extended survey area in 2014. It is more evenly spread over its area of distribution than most of the other reported species. This is also reflected in the low CVs of the abundance indices.

## Capelin

No quantitative acoustic or trawl indices have been calculated for capelin. Capelin is normally found throughout the investigated area; mainly immature fish is found north of $74^{\circ} \mathrm{N}$ while maturing, prespawning fish is found south of this latitude. The mapped distribution of capelin in bottom trawl seems to correspond well with the distribution of capelin in cod stomachs. An interesting feature is that the smallest cod, which generally eat small amount of capelin, seem to contain more capelin in the northern areas than in the southern. This probably reflects the length distribution of capelin: smaller capelin in the north are more suitable as food for smaller cod, while small and large capelin in the total distribution area constitute a major prey item for larger cod.

## Polar cod

Polar cod are not well represented in the trawl hauls during the winter survey. This reflects the more northern and eastern distribution area of this endemic arctic species. During this time of the year, the polar cod is known to be spawning under the ice-covered areas.

## Blue whiting

The echo abundance of blue whiting in the survey area peaked in 2006. Since then it has decreased considerably. High abundance of fish below 20 cm , e.g. in 2012, reflects abundant recruiting (age 1) year classes.

## Appendix 2. Changes in survey design, methods, gear etc.

| Year | Change from | To |
| :---: | :---: | :---: |
| 1984 | Representative age sample, 100 per station | Stratified age sample, 5 per 5-cm length group |
| 1986 | 1 research vessel, 2 commercial trawlers | 2 research vessels, 1 commercial trawler |
| 1987 | 60 min . tow duration | 30 min . tow duration |
| 1989 | Bobbins gear | Rock-hopper gear (time series adjusted for cod and haddock) |
| 1990 | Random stratified bottom trawl stations Simrad EK400 echo sounder | Fixed station grid, 20 nm distance <br> Simrad EK500 echo sounder and BEI post processing |
| 1993 | $\mathrm{TS}=21.8 \log \mathrm{~L}-74.9$ for cod and haddock | $\mathrm{TS}=20 \log \mathrm{~L}-68$ for all demersal species (time series corrected) |
|  | Fixed survey area (A,B,C,D), 1 strata system, 35 strata | Extended, variable survey area (A,B,C,D,D', E,S) |
|  | Fixed station grid, 20 nm distance | 2 strata systems, $53+10$ strata <br> Fixed station grid, 20/30/40 nm distance |
|  | No constraint technique (strapping) on bottom trawl doors | Constraint technique on some bottom trawl hauls |
|  | 5 age samples per 5-cm group, 2 per stratum | 2 age samples per $5-\mathrm{cm}$ group, 4 per stratum (cod and haddock) |
|  | Weighting of age-length keys by total catch | Weighting of ALK by swept area estimate |
| 1994 | $35-40 \mathrm{~mm}$ mesh size in cod-end Strapping on some hauls | 22 mm mesh size in cod-end <br> Strapping on every 3. haul |
|  | Hull mounted transducers | Keel mounted transducers Johan Hjort |
| 1995 | Variable use of trawl sensors | Trawl manual specifying use of sensors |
|  | Constant effective fishing width of the trawl | Fish size dependent effective fishing width (time series corrected) |
|  | Strapping on every 3. haul | Strapping on every 2. haul |
|  | 2 research vessels, 1 commercial trawler | 3 research vessels |
| 1996 | 2 strata systems and 63 strata, 20/30/40 nm distance | 1 strata system and 23 strata, $16 / 24 / 32 \mathrm{~nm}$ distance |
|  | 2 age samples per $5-\mathrm{cm}$ group, 4 per stratum | 1 age sample per $5-\mathrm{cm}$ group, all stations with > 10 specimens (cod and haddock) |
| 1997 | 16/24/32 nm distance | 20 nm distance |
|  | Hull mounted transducers | Keel mounted transducers G.O. Sars (Sarsen) |
| 1998 | Strapping on every 2. haul | Strapping on every haul |
|  | 20 nm distance | 20/30 nm distance |
| 2000 | 3 Norwegian research vessels | 2 Norwegian and 1 Russian research vessel |
| 2002 | 20/30 nm distance station grid | 16/20/24/32 nm distance station grid |
| 2003 | Height trawl sensor for opening and bottom contact | Trawl eye for opening and bottom contact |
| 2004 | Vaco trawl doors | V- doors G.O. Sars and Johan Hjort |
|  | EK 500 and BEI Sarsen | ER60 and LSSS G.O. Sars |
| 2005 | EK 500 and BEI | ER60 and LSSS Johan Hjort |
|  | EK 500 | ER60 Russian vessels |
| 2006 | Standard Campelen rigging | "Tromsø rigging" on Norwegian vessels |
| 2008 | V trawl doors | Thyborøn doors Jan Mayen/Helmer Hanssen |
| 2010 | V trawl doors | Thyborøen doors G.O. Sars and Johan Hjort |
| 2011 | 30 min . tow duration | 15 min . tow duration |
